VOL. XLII. JANUARY 7, 1898. No. 1,050.

CONTENTS:

THE ELECTRICAL REVIEW.

Published every FRIDAY, Price 4d.

The Oldest Weekly Electrical Paper. Established 1872.

TO BE OBTAINED BY ORDER FROM ANY NEWSAGENT IN TOWN OR COUNTRY.

OFFICE:—4 LUDGATE HILL, LONDON.

Telegraphic Address: "AGEEKAY, LONDON." Code A B C.

Telephone No. 963 Holborn.

ALL Letters should be addressed to the Proprietors, H. Alabaster, Gatehouse & Co.

ADVERTISEMENT RATES ON APPLICATION.

The "Electrical Review" is the recognised medium of the Electrical Trades.

SUBSCRIPTION RATES.—In *Great Britain*, Post Free per Year, 19s. 6d. To all *other countries*, per Year, £1 4s.

BINDING.—Subscribers' numbers bound, including case, for 4s. each volume.

CASES.—Cloth Cases for Binding can be had, price 2s. 6d. each.

READING CASES, to hold from One to Twenty-six Numbers until the Volume is complete for Binding, can now be had from the Publishers, Price 6s. or Free by Post (in Great Britain), 6s. 6d.

FOREIGN AGENTS.—*New York:* D. VAN NOSTRAND, 23, Murray Street. *Paris:* VEUVE J. BOYVEAU, 22, Rue de la Banque. *Berlin:* ASHER & Co., 5, Unter den Linden.

Cheques and Postal Orders (on Chief Office, London) to be made payable to Mr. H. ALABASTER, 4, Ludgate Hill E.C.

THE ENGINEERS' STRIKE.

CURIOUSLY enough the *Engineer* of last week propounded the idea that the strike was past help or advice, and the daily press of even date contained a notification from Cantuar and Ebor, which are understood to stand for the Archbishops of Canterbury and York, commending the whole business to prayer. It is recorded among the profane that when two men were cast away in an open boat and felt themselves to be very much *in extremis*, they deemed it necessary to pray. They were unequal to this, so a hymn was suggested. This also proved to be outside the sphere of their practical politics, and, as a last resource, in order that something religious should be done, they had a collection, that perennial joy to the churchgoer which possibly so well answers the oft-repeated cry, "Why do not the poor go to church?" Our good archbishops have seen probably that it is to long-continued collections that the strike owes its continuance, and so they have turned to prayer. Well, this is better than the ill-informed interference of the Bishop of Hereford. On the bishop's interference we cannot do better than quote the *Engineer* as follows:—"If, for example, the bishop could be led to understand the position in which he would be if his coachman refused to permit his lordship to use his carriage as he pleased, limited the hours during which it was to be out of the coach-house, refused to permit anyone else to drive it but himself, settled the rate at which it was to be driven, and the number of individuals it was to carry, and lastly, if dismissed for incompetence, or refusal to obey orders, took all the rest of the bishop's household with him, and then prevented him getting others in their places, we fancy the bishop would regard the position of the employers in the present struggle with a little more favour."

We hope someone has sent this copy of the *Engineer* to the good bishop, because it puts the whole case in a nutshell. The carriage is a machine in which a rich bishop is carried from place to place, where a poor clerk would have to walk. It is a luxury under the full control of the bishop. A machine tool is a machine costing, as a rule, more than a carriage. It is not a luxury, but is used as a means of obtaining bread and clothing for an employer and his family, and that of the man who is paid to work the machine. Yet this necessity—for a machine tool is a necessity—is to be provided by the employer, housed by him, and he is not to have a word to say as to how it shall be worked, but is to pay a fixed sum to have a man attend to it, and receive himself no return. It is as though the bishop were compelled by his household servants to keep a carriage, but only allowed to use it himself when no one else wanted it.

If the bishop did not approve he could, of course, cease, as the law now stands, to use it, he could cut off his carriage and the annoyance at once. He could walk, and no one would be the worse, except the coachman; indeed, the bishop would probably benefit by the exercise. But England would not suffer by the suppression of 50 bishops' luxuries.

England does suffer if a single machine tool is stopped or hindered, and the very men suffer the most who are doing the evil deed. Last week we proposed a new form of trades union which we hoped might at least provide food for thoughts that would lead to something being done. Further thought on the subject has not moved us from our feeling that the scheme, we ventured to propound, has in it the elements of success. We know the difficulties in the way. Men have been too prone to throw aside the decision of arbitration when it suited them to do so. The employers repudiate outside interference, for they have already had so much of it with such ruinous results, that they are strong in their refusal to budge an inch. We do not wish to appear unduly unfavourable to the men, but we are, and have been, convinced that their executive are elected or appointed in a wrong manner. We think that if our suggestion of a permanent joint committee could be brought about, the men's representatives should be drawn from the various districts in the country according to number of members in the different districts. No man should serve longer than, say, three years, and every year one-third would retire and go back to the bench. The pay of a member should be little more than his wages. Votes should accrue to the men for purposes of election in the ratio of their years of membership. This would steady the ship greatly.

As the war is now going on again in full blast, we would appeal to the men, especially to the older and steadier among them, to carefully consider their present status, and the true facts of the present dispute. We would ask them, Does it appeal to your common sense that machinery should be run slowly to reduce its output? Does this cause commend itself to you as a means for you to earn higher wages? Does it not occur to you that the mechanics of America, whose skill as a mass is not greater than that of the labourers who work machines in English shops, are earning bigger wages very largely because American shop management is conducted upon the lines you are fighting against? Can you not see that your persistence in your present course can have only one of two endings? Either you must be hopelessly beaten, or trade will go to foreign countries, and very few of you will get back again to work. Can you not already see that you are fighting against sense and reason, as did the mistaken Luddites and machine wreckers generally? We tell you plainly you cannot win this battle, into which we know from conversation with many of you, you have been driven by a fatuous and wicked policy. For six months you have been fighting, and for what end? If you are wise, you will reconsider your position and place trades unionism on a sound basis. You will put a stop to the use of benefit funds for fighting purposes. You will have a secretary whom you can dismiss at a day's notice if he misbehaves himself, or mistakes himself for the Almighty.

Above all, beware of talkers. When a man like John Burns goes on a platform and says he will have the strike all over in a fortnight, as he did say half a year ago, you believe him; you always do believe these stump orators; they turn a working man inside out, because working men, as a rule, are not prone to making speeches, and are apt to take the ability to talk as evidence of wisdom. Are not the sufferings of the past half year a severe enough lesson for believing Mr. Burns, that you must still go on believing men who are leading you deeper and deeper into the depths of misery and poverty? Do you not know that every week sees the workshops getting into fuller work *without your aid*, and that unskilled labourers and apprentices are proving the possibility of easily doing more and better work than your executive has been allowing you to do, on the pretence that, to obtain a full day's pay for half a day's work, is to your benefit? Can it be possible that you believe these absurdities? Are you willing to allow Mr. Barnes to continue to trade on your simple trust? There are about half a million men in the engineering trade, and only about 80,000 of them are members of the A.S.E.; of these 80,000 there are 55,000 at work under the very conditions which you are striving against, and they do not complain, but are earning good wages, working overtime, and paying levies to keep you idlers half fed. There are 25,000 of you, or, perhaps, now nearly 30,000, undergoing semi-starvation for a false idea. One man of you is out of work for every 19 men, unionist and non-unionist at work. Are you willing to go on with a hopeless fight while the other 19 are in full swing? Go back to work. See to it that English workshops turn out as much per man as the workshops of America, by putting a stop to this folly of restriction. Let the employers have a free hand to manage their business and a heart to seek orders and take contracts with no misgiving, and then ask them to raise your pay.

If you act as above, the profits of the employers will be so ample that not one of them will care to risk their stoppage by refusing your proper demand. In the present dispute you have made an unreasonable demand upon your employers, and you have been in the position of a footpad, who, in asking a man for his purse, has given him the alternative of death by shooting if he acceded or by drowning if he refused. Even a coward will fight if he must otherwise die. You have compelled your employers to fight for their lives, and you have been beaten; and if you had won, there are two men behind the hedge would take the spoil, and leave you as dead as your employer. These two men behind the hedge are encouraging you, and helping you to fight your employer until you are both exhausted. Their contributions will cease as soon as they see both you and your employer have bled each other to death.

Men of the Amalgamated Society of Engineers! have you positively ascertained that among the agitators who are goading you on to your doom there is not one who is in the pay of Germany or America?

Note on Helium and Argon.—An attempt has been made to cause helium or argon to pass through red-hot metals, such as iron, palladium, and platinum, and the results form the subject of a paper by Prof. William Ramsay and Morris W. Travers, which was communicated to the Royal Society on May 14th. To chronicle experiments which produce no result is a necessity, though not entirely an agreeable one. Whatever the reason of the passage of hydrogen through red-hot iron, and through moderately heated palladium and platinum—whether it be due to the solubility of the gas in the metal, or to the formation of an easily decomposable compound—neither argon or helium is able to pass through any one of these metals, even at a fairly high temperature. This would imply their inability to form any compound, however unstable, with these metals, or to dissolve in them at a red heat. Such inactivity is in accordance with their general behaviour, and is still another proof of their inertness.

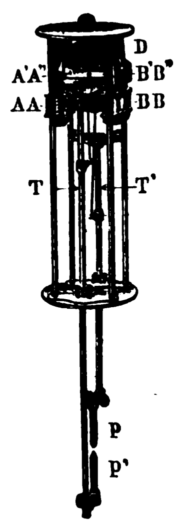
HENRION'S ALTERNATING ARC LAMP.*

By M. ALIAMET.

ALTERNATING current arc lamps are beginning to be somewhat extensively used, and, with the exception of a few rare types, their regulating mechanism does not act very satisfactorily with the alternating current, at any rate with frequencies included between 39 and 45, these being the prevailing limits in France at least.

The firm of Fabius Henrion, which at one time brought about a revolution in the market of continuous current arc lamps by bringing out the Pilsen lamp, has just produced a regulator for alternating current lamps, with an asynchronous reversible motor to effect the regulation.

Principle.—The two carbon-holders, *p p'* (see figure), are balanced and kept in position by a band to which they are



suspended. This band passes into the groove of a pulley, P, on the axle of which is mounted a disc, D, of red copper.

It is this disc that, by turning in one direction or the other, separates the carbons or brings them together. The rotary movement is obtained by the following arrangement:

An electro-magnet, A A, with a core of insulated sheet-iron, has its pole-pieces shaped in the form of jaws, A' A", between which comes the edge of the disc, D. The bobbins of this electro are connected in series with the arc, and the play between the disc, D, and the pole-pieces, A' A", is reduced to a minimum.

When the current passes through the bobbins it generates an alternating flow in the electro-magnet; this flow is closed in the air on passing through the disc, D. The flow produced by the bobbins agrees within very little, with the difference of potential at the terminals of the lamp, whereas the magnetic field developed by the currents induced in the disc, D, lags by about a quarter of a period behind this difference of potential.

Repulsion is then produced between the periphery of the disc and the pole-pieces, the effect being of the kind of the electro-dynamic repulsions discovered by Elihu Thomson in 1884. Every point of the disc tends to be repelled in an upward direction, away from the field of the electro-magnet A A' A". The disc then turns in the direction of the hands of a watch; moreover, the couple is greater in proportion as the intensity of current is stronger. At B B, B' B" is another electro-magnet, the bobbins of which are connected in derivation on the terminals of the lamp. This magnet tends to make the disc revolve in the opposite direction to the hands of a watch by the very fact of its symmetrical position with regard to the magnet A A' A". The couple produced in this last case is in proportion to the ampere-turns acting on the magnet B B' B", *i.e.*, to the difference of potential at the terminals or to the length of the arc.

Lastly, the disc, D, acts as the armature of an asynchronous motor with two independent inductive fields acting in opposite directions on this common armature. The rest of the construction of this lamp reminds us very much of the Pilsen model. There is the same case, the same guiding apparatus for the carbon-holders, T T', which pass through the lower base of the case, being guided by three rollers placed in three planes 120° apart. This arrangement ensures the perfect centreing of the carbons.

Working.—When the current is sent through, the carbons being separated, for instance, the magnet, B B' B", acts alone, and makes the disc, D, revolve so as to bring the carbons together. When they are in contact, the current passes into the electro-magnet, A A' A", and makes the disc revolve, thus separating the carbons, for, at the moment of contact, the electro-magnet, B B' B", ceases to act. The arc being thus lighted, regulates itself according to the predominance of effect of the A A' A" or B B' B".

The lamp is therefore differential, and a recoil can always be produced and the arc relighted when, through any cause, the carbons come in contact. The production of this recoil is a necessary consequence of the independence of action of the magnets in series and in derivation.

The lamp is regulated to work at 33 volts, so that three can be connected in series at 110 volts.

Two types are in course of construction which only differ in the length of the working range of the carbon-holders. The smaller model enables 400 mm. of carbons to be used, and allows of from 6 to 10 hours of lighting.

The larger model has a length of 560 mm., and, according to the diameter of the carbons, has a duration of 8 to 16 hours.

The steadiness of the light is guaranteed, and also the fact that the lamp requires no attention or cleaning. It seems that the motor answers to a variation in E.M.F. of ·1 of a volt, which seems somewhat exaggerated. What surprises us somewhat in this lamp is the absence of any slackening apparatus for the purpose of avoiding pumping.

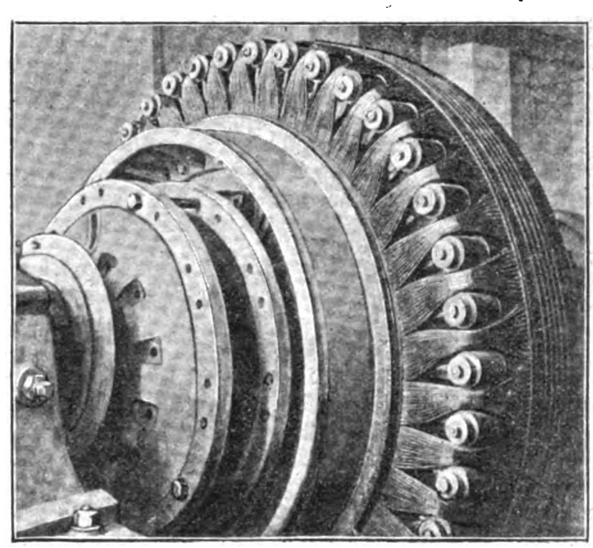
GENERATORS IN THE UNION LOOP STATION.*

THE illustration represents the armature and commutator of one of the Siemens & Halske 1,500-kw. generators now being installed in the Union Loop power house in Chicago. The arrangement of the armature winding and the connections to the commutator are clearly shown. This construction has all the advantages of internal fields; great radiating



surface and maximum magnetic effect are to be found. The commutator is on the armature spider, and its construction and insulation are for large current capacity and long life. The armature winding is such as to give good ventilation. The poles will be 16 in number.

The armature was entirely assembled at the company's works and had to be transported on a special car, on account of its great size and weight. For such service the company has designed and built two or three flat cars, with two out-

* *Street Railway Review.*

board bearings, on either side of the car near the middle. The armature shaft rests on these bearings and part of the armature projects beneath the car floor, but far enough above the roadbed to prevent any damage from obstructions there. By this means armatures of very large diameter can be transported and come beneath the limit of height prescribed by the railroad companies. This armature had to be moved for some distance through the streets, from the tracks of the Chicago & Northern Pacific to the station. The trucks were removed from under the car body and it was let down on skids and pulled along on rollers by means of a capstan. The rest of the machine is so divided as to be easily handled.

This is the first of three machines to be installed in a short time, and the work on the station is being pushed as rapidly as possible.

CANDLE-POWER OF ARC LAMPS.

We (*Canadian Electrical News*) have already had occasion to refer to the candle-power of arc lamps, and the very indefinite way of specifying it. It seems to have become fixed in the minds of a large number of persons that a 9·6 ampere arc lamp will give 2,000 candle-power, and that a 6·8 ampere will give 1,200 C.P. When, therefore, such lamps are put into circuit, and seem to give a light deemed not up to their standards, disappointment and dissatisfaction result. The manufacturing companies are blamed for trying to sell under worthless guarantees, and the customer considers himself badly treated. Now, it is not the business of this journal to take the part of manufacturers against the public, but we deem it in the true interests of the electrical industry to point out to our operating readers that the above dissatisfaction is most emphatically largely their own fault. A man who does not take the trouble to study the details of a business out of which he makes his living almost deserves to be deceived, more especially when the whole literature of the subject is at his disposal, is extremely interesting, and written in a state to suit not only the technical, but also the popular reader. When purchasing an arc dynamo the purchaser usually asks for a 2,000 or a 1,200 C.P. outfit, and without giving the matter a moment's thought, concludes that a "nominal" 2,000 C.P. lamp will give actually 2,000 C.P. If he were to devote to the subject as much thought as he gives to the purchase of a hand lamp for his kitchen—to use oil—it would probably occur to him that just as the amount of light given to his coal oil lamp depends on the quality of the oil, the size of the wick, and whether the wick is turned up or down, so the light given by an arc lamp depends not merely on the current, but also on the quality of carbons, their size, and the distance between their points. As a matter of fact, anyone can prove for himself that one can get more light from a 5-ampere lamp than from a 10-ampere one, by simply varying the size, quality and distance of the carbons. An arc lamp is nothing more or less than a mechanism for keeping two carbon rods always a little distance apart, and the lamp itself has no more to do with the light than has the bulb of the hand lamp that holds the oil, or the screw that raises the wick. So that if a purchaser desires to buy arc lamps properly, he should not ask for one of a particular candle-power, but for one adapted for the use of a certain current to maintain the carbon rods a certain distance apart, and with a certain drop of potential across its terminals. The candle-power is then entirely his own affair, and if he wishes to be very severe in his requirements he will then need to specify that with such a lamp as above, and using carbons of such and such a particular make, the candle-power observed at such and such a distance from the crater, and at a specified angle from the horizontal plane passing through the crater, must be what he considers he wants. With a specification such as this he is equipped and is in a position to talk to manufacturers, but to consider himself badly treated and deceived because a lamp bought as a supposed 2,000-C.P. does not give it with any kind and size of carbon, and at any distance from the ground, is just about as business-like as to buy a heating stove without saying whether it is to burn wood or coal. As a matter of fact it has been over and over again again proved that a nominal 2,000 candle-power lamp does not give more than 800 C.P. in the most intense direction with ordinary carbons, &c. If the electrical operating industry would take a hold of its interests a little better and would dictate its requirements it would be better for both operators and manufacturers.

ONE OF THE USEFUL APPLICATIONS OF THE STORAGE BATTERY.*

By WILLIAM BAXTER, Jun.

When the storage battery first came prominently before the world, it was thought that its great field of usefulness would be that of the transportation of energy from coal fields and large water power sites to centres of industry. It was also believed that it would enable the electric motor to become a formidable rival of the steam locomotive, not only because it would reduce the cost of hauling a train, but because, in addition, it would remove many of the objectionable features of steam transit, such as smoke, cinders, &c. When put to the test it was found that the batteries, at least as then constructed, could not withstand the hard usage to which they were subjected in railway work; and as to their value as transferrers of energy from the source of supply to the points of demand, it was found upon investigation that they could not compete with existing methods, even if made sufficiently substantial to endure constant usage with slight deterioration, and so perfect electrically as to have the greatest storage capacity, per unit of weight, consistent with theoretical possibilities. In this latter field they would necessarily fail, because, if made as light as possible, they would weigh at least 12 lbs. for each horse-power hour capacity, and as good steam engines can develop the same amount of energy from 3 or 4 lbs. of coal, the weight of batteries to be transported back and forth would be three to four times that of the coal necessary to do the same work. The batteries then made weighed from 150 to 200 lbs. per horse-power hour capacity, instead of 12; hence, the difference in weight to be transported under the actual conditions was so great as to render it impossible to accomplish anything practical in that field, even if the energy could be obtained free of cost.

When it was seen that the storage battery could not accomplish anything of a revolutionary character, those interested in its development began to study its adaptability to less pretentious work, and soon realised that it would be decidedly valuable as an adjunct to electric lighting stations, as it would be to these what the gasometer is to a gas distributing system—a reservoir from which the demand of customers could be supplied, should it become necessary at any time to stop the machinery for a few hours. Without the aid of storage batteries, if from any cause the operation of the generators is suspended, the lights will instantly go out and remain out until the generators are set in motion again. After years of persistent and very commendable experimental work, the inventors of storage batteries succeeded in making these devices sufficiently durable to withstand the wear and tear they are subjected to in station work, without unreasonable deterioration. Since that time they have been used to a considerable extent in that field, and within the last two years their use has been increasing at a very rapid rate; in fact, a first-class station of to-day would not be considered complete without a storage battery plant.

The first battery plants installed in lighting stations were intended simply as a safeguard, to render it possible to keep up a supply of current in case of accident to the machinery; but it was not long before it was realised that by enlarging the capacity of the batteries, the output of the station could be greatly increased without materially increasing the expense of operation. How this result can be accomplished will be readily understood when it is considered that the demand for light is not uniform throughout the whole 24 hours, but varies from little or nothing, during the day and the early hours after midnight, up to to the maximum

* *Scientific American.*

amount between 9 and 10 in the evening. The station capacity, however, must be sufficient to meet the greatest demand; therefore, during the greater part of the time the machinery is only worked to a fraction of its full capacity. By using storage batteries, the generators can be worked to their full capacity all the time, and when the demand of consumers is small the surplus energy is stored, to be given out when the demand is in excess of the amount developed by the machinery.

From the very fact that the demand for current is variable, it becomes possible for batteries to be used not only to reduce the cost of production and increase the capacity of the station, but also to reduce the cost of line wires. This last result can be accomplished in any case where the station is located at some distance from the district in which the current is distributed. To illustrate this point, suppose the station is located, say, one mile from the centre of the city or town in which the lights are used. If the current runs direct from the generators to the customers' lamps, the line wires must be of sufficient size to carry the maximum supply with a loss of pressure low enough to not interfere with the brilliancy of the light. If the maximum demand lasted for a considerable portion of the day, the full capacity of the line wire would be used to a reasonable extent, but the duration of this maximum demand is seldom over one-half, or, at the most, one hour; therefore, during the rest of the time a large portion of the line capacity may be regarded as wasted. The difference between the average and the greatest demand varies within wide limits, in different stations, but in the majority the ratio is not much below one to two. Whatever it may be, however, if the current could be supplied at the average rate, and the excess over the demand when the consumption is small were stored, the amount so stored could be used to supply the deficiency when the demand is large. This is accomplished in many cases at the present time by placing a storage battery plant at the centre of the district in which the customers are located. The wires coming from the generating station are so connected with the battery and the distributing mains that, whenever the drain is less than the current coming from the station, the batteries are charged, and when the demand is in excess of the current from the station, the battery feeds into the distributing mains. The current passing from the generating station to the battery station is about 10 per cent. more than the average demand, so as to cover the loss in the charging and discharging of the batteries.

The saving in wire by this arrangement will run from about 25 to 75 per cent., depending upon the relation between the average and the maximum current, and also upon the amount of energy that is lost in transmitting the current from the generators to the battery. When the generating station feeds directly into the distributing mains, the loss of energy in transmission is governed by the condition that the pressure of the current must not drop so much as to interfere with the brilliancy of the lights, and therefore, the line loss is generally low; but when batteries are used, located at the centre of distribution, they regulate the pressure of the current supplied to the lamps; and, therefore, the loss between generator and battery may be made anything desired, without affecting the brilliancy of the lights. If the power is obtained from a waterfall or from coal near a railroad, when it can be obtained at a very low price, it may be more economical to increase the loss of energy between generator and battery, and thus reduce the cost of line wire, but such conditions cannot be taken advantage of if the battery is not used.

ELECTRICAL BOOKS—PRACTICAL AND ELEMENTARY.

"Oh, that mine enemy would write a book!" is a wish that might not inaptly proceed from the thoughts of many a practical electrical engineer to-day, for undoubtedly were the said enemy to do so, it may be taken for granted that the work would be constructed upon the same lines that have now apparently become stereotyped, and thus would arise the opportunity for attack. Perchance from out of the resulting conflict might arise some truths that would impress themselves upon those who seek to impart their knowledge of electrical engineering to their less learned brethren. That the writers responsible for many existing treatises have not been assailed more often is possibly due to the imposing effect of the professional character and reputation that surround them, or it may be that they are fortunate enough to exist without enemies.

Nevertheless, it is a fact that a current of opinion is commencing to flow, which will, sooner or later—and the sooner the better—sweep away not a few prevailing opinions as to the proper manner of compiling the works required by the electrical engineer for the furtherance of his knowledge.

Almost the first impression that one receives after studying a few of these books, both those recognised as standards, and others of less note, is that each individual author seems to arrogate to himself the honour of being the reader's sole teacher of all the elementary facts regarding electricity. In the case of a work that is not only professedly but *actually* introductory to the study of a subject, no objection of this nature can reasonably be made. The majority, however, while claiming on their title pages, or in the prefaces, to be elementary, have, as a matter of fact, ceased to be so, long before the concluding chapter is reached. In a very limited sense they may indeed be termed "elementary," but for all practical purposes this description is misleading, and affords no complete and real intimation of the nature of the contents. A work that, for instance, discusses, amongst other things, the design of 500 kw. dynamos, the effects of self-induction in alternators or combinations of resistance, self-induction and capacity of transformer circuits, cannot fairly be regarded as elementary, even though it also deals in its early part with the units of measurement or the method of calculating horse-power. While it is true that instruction in first principles is necessary in order that a grasp of any branch of electrical science may be obtained, it does not follow that the beginner should be dragged through the whole range of electrical engineering in one volume; and, conversely, the man who has passed the initial stages should not be expected to go over again and again work with which he already is conversant. Some day it will dawn upon a writer that the average engineer who seeks to enlarge his knowledge has gone through the electrical alphabet, and no more requires to repeat his letters than he does to learn his own name. Then all those points of information which at present seem to be included in the majority of works—the statements regarding the supposed natures of electricity, the description of simple experiments from the rubbing of amber or sealing wax, to that hoary-headed and inevitable old friend, the demonstration of the lines of magnetic force by means of iron filings on a card,—these and the multitude of others will become incorporated into true elementary works alone. Everything has its place, and there is just cause for complaint at the inclusion of these facts in works that subsequently attain to heights quite above the reach, for some time to come, of the learner who is a learner from the beginning.

The practice is to be regretted for more reasons than one. Even in the case of those who have justly earned the right to be regarded as the authors of standard works, it would undeniably be of benefit to their writings if a division into different volumes of elementary, middle, and advanced stages were made. Thus each course would receive more ample and explicit treatment than is now practicable, owing to the necessity of paying due regard to considerations of space.

To the electrical engineer a technical library of his own is an absolute necessity; more often than not it is formed slowly, for generally the princely remunerations that are the rule in this, the richest country in the world, become in most cases attenuated almost to the vanishing point when the ordinary cost of living has been met, and consequently books can only be indulged in at infrequent intervals. When the majority of works that in their main part are really helpful to the practical man, each contain from one to five, or more, chapters devoted to the simple elementary principles of electricity before proceeding to instruct in modern methods and applications (the matter that sells the book), an injustice is done to the purchaser, who has to take what he does not want, in order to obtain that which he does. It may perhaps be contended that one or two standard works on any theme contain practically all that the average man requires to know, therefore no real ground for objection to the inclusion of the introductory course exists, seeing that these are sufficient in themselves for instruction in the subject they deal with.

Admitting, for the sake of argument, that it is not necessary to possess more than this number, there still remains the fact that knowledge should be imparted in accordance with the needs of the learner. To assume a man's complete ignorance of everything connected with electricity because he asks for information on dynamo design or polyphase power transmission practice is nothing less than to offer him an insult. A writer on the derivation of language does not commence a treatise by instructing his readers how to spell, neither does the political economist consider it necessary to first explain to his disciples the meaning of such words as "land," "king," or "people." And yet this is precisely the kind of error that so many writers of electrical books commit to-day! With the class of works compiled expressly for the use of the students of A Technical College, or B Engineering Institution these remarks are not now dealing. Such form a class to themselves, and exist for a specified purpose that is distinct from the one under discussion. But in the case of those put forward for the use of the practical electrical engineer—the man who is engaged in handling, operating, or manufacturing apparatus and plant—it is time that attention should be paid to actual requirements.

The present mode of treatment would appear to be a survival of that past day when the various branches of electrical science were more or less in an embryo state—when, in fact, electricity was "in its infancy"—and could be adequately dealt with between the covers of one volume. The advance of knowledge has already brought us specialised works; it yet remains to separate in these the elementary portions from the more advanced. With the accomplishment of this "consummation devoutly to be wished" will come a satisfaction to the young beginner, to the practical man, and last, but not least, to the author.

SOME PRACTICAL POINTS ON THE DESIGN OF A SHUNT DYNAMO.

By V. ZINGLER, A.I.E.E.

So much has been written, and is still being written, on the design of dynamos as they now are, that it is, perhaps, difficult to attack the subject from any point of view without having been anticipated, or in default of this, without being expected to say something quite new or to announce some startling discovery. It has, however, occurred to the writer that very little is found either in text-books or in papers, other than the theoretical discussion of the question, and if examples of building up and winding are given, they are usually obtained by working backwards from a dynamo which the author has before him, or of which he has all the finished data; or else the usual well-known formulæ are given and the winding is then laid on—piled on—as it were, without any reference to small details of insulation, &c., which are so absolutely necessary in making out specifications for the shops—quite apart from considerations of a physical kind.

The object of these notes is, therefore, not to discuss formulæ or the methods by which they are arrived at (it will be assumed that the reader is acquainted with the dynamo design as set forth in text-books, and the elementary theory of magnetism), but an attempt will be made to show how a dynamo may be calculated from first principles so that it may be put into the shops, and so that the winding as specified by the calculations will actually go on. In order to simplify matters we will take an ordinary two-pole inverted shunt dynamo with drum armature, a type such as is perhaps more frequently employed than any other. The methods we employ for winding this machine will of course hold good—as far as mechanical considerations go—for any other type of machine; the electrical considerations will, of course, vary according to the type of machine, but with these it is not proposed to deal, except so far as they concern the particular machine under discussion; the designer will use the same methods for winding different types of machines, and in accordance with his particular shop practice, although many other *forms* of winding have to be employed to give the various electrical duties required from more complex types of machines. The words "shop practice" are perhaps the only ones which raise any difficulty in the subject before us and which obliges us to assume something; for every shop has its own particular data as to insulation of the various parts of the machines, thickness of insulation for different voltages, method of forming armature bars, of winding same on the core and so on—which ultimately determine the whole method of building up the machine, although its efficiency and weight for output may be the same in any number of shops. The designer has therefore to fix on certain insulating materials, to gauge them accurately and to always keep these figures before him as constants. He has also to decide on a definite way of building his machine and then to use these constants in his calculations for winding.

We will, therefore, decide on building our machine in a definite way, and perhaps the simplest case is to assume that the armature should be built up of round core discs and the bars or wires laid on the periphery and keyed by wooden pegs, thus forming part of the air-gap. We will also assume that the bars are built up of copper strips of a minimum gauge of ·036 inch, placed edgeways on the core; the component strips of one bar being separated by thin paper to stop eddy currents. The bars will be wound round with shellaced cotton or other tape to a thickness of ·02 inch; the armature core will be insulated from the bars by means of presspahn or other insulating material to the thickness of ·05 inch; and the finished armature will be bound with piano wire over mica insertion to thickness of, say, ·065 inch. These figures are such as are used in actual practice, and may, for convenience of reference, be tabulated thus:—

Insulation on bars	·02 inch.
" " wire (d.c.c.)	·008 "
" " core	·05 "
Wire bands and mica	·065 "
Paper	·003 "
Minimum copper strip	·036 "

In any case, the designer will gauge the particular materials he proposes to use and endeavour to see that these do not vary in thickness.

In order to more easily demonstrate the process of winding, we may assume that a machine of a certain output is required, and that there are no other data to hand by which this machine can be approximated from others. For when a dynamo has once been built and another is required which varies only slightly in amperes, speed, or volts, or any combination of these, it is seldom necessary to do more than to alter either the winding of the armature, the section of the iron, or the winding of the fields. Dynamos of any one type are rated by the number of watts per revolution, and it is found in practice that, after taking a certain diameter of armature, a machine can be built round this up to a limited number of watts per revolution only—that is, after the armature has become twice the length of its diameter, in order to allow for an increased section of iron; or after the current has become so big that the size of bars required to carry it have reduced the number of bars to less than 40; or if the field winding takes up so much room that it cannot be put on the magnets without causing serious overheating due to want of radiating space; these, and several other factors, determine a figure for the watts per revolution (= w.p.r.), after which it becomes necessary to take a larger diameter for the armature.

Having then established a certain number of sizes of machines as fixed by their armature diameters or w.p.r., we can, within limits, tell at a glance on seeing the output required for a dynamo, what size of machine to take. This, of course, would not apply to plating dynamos or high voltage machines.

We will now take a machine with the following output:—400 amperes, 80 volts, 320 revolutions per minute (an Admiralty size). This gives 100 w.p.r.

We have now to decide on the size of armature, and it may be convenient to standardise our armatures by the diameter of the bore of the magnets—that is, the diameter of the armature if the air-gap were infinitely small. This allows us to vary the depth of winding or the diameter of the core plates without reference to the diameter of the armature. The question therefore arises: given our output, what sized armature shall be taken. This we can arrive at approximately in the following manner. Our fundamental equation is:—

$$N = \frac{E \times 60 \times 10^8}{n \times c}$$

where N = total number of magnetic lines.
n = revolutions per second.
c = number of convolutions or bars.

It is clear then that c is the only quantity wanting to determine N. Now, in fixing c, we are met by two considerations: (1) that c should not be much greater than 160 owing to expense, or below 40 owing to sparking; also (2) that it should be an even integer and preferably divisible by 8. Let us take $c = 120$, which will give us approximately the value we require for N, and will allow of altering the actual number of bars afterwards either way.

We therefore get

$$N = \frac{80 \times 60 \times 10^8}{320 \times 120}$$

$$= 12{\cdot}5 \times 10^6 \text{ nearly.}$$

To N we should add 10 per cent. for armature and demagnetisation losses $= 13{\cdot}75 \times 10^6$. Assuming our induction in the core to be 10,000 lines per square centimetre, this gives a total area of 1,375 square centimetres. To this we must again add about 20 per cent. to allow for the shaft, whose permeability will be much lower than that of the soft iron core, and also for the ventilation shafts through the core—always assuming that the armature is very little longer than its diameter.

This gives us 1,650 sq. cms., or about 250 sq. ins. to deal with. Now we have 120 conductors, and assuming a depth of bar of ·5 in., and a current density of 1,500 per sq. in., the area of bars will be

$$\frac{200}{1{,}500} = {\cdot}1333 \text{ sq. in.,}$$

and the breadth of bar = ·266 in., or with paper insulation, &c., about ·325 in.

The total periphery required will thus be

·325 × 120 + say 2 inches for pegs = 41 inches say 42 inches,

and the diameter of core

$$= \frac{42}{\pi} = 13\tfrac{1}{2} \text{ inches.}$$

The length of core will be

$$\frac{250}{13{\cdot}5} = 18{\cdot}5 \text{ inches.}$$

The core for 120 bars is thus $13\frac{1}{2}$ inches × $18\frac{1}{2}$ inches.

But as our desire is to make the core nearly square, even if a few more bars are put on, it can be made

$$15\tfrac{1}{2} \times 16 = 250 \text{ sq. ins. nearly.}$$

Now, assuming $\frac{3}{4}$-inch air-gap all round (our bars are $\frac{1}{2}$ inch deep), this gives us 15 inches + $1\frac{1}{2}$ inch, or, say, 17 inches for bore of pole-pieces, or armature rating.

Having now fixed the size of the armature (and as explained before, this can be done forthwith after a little experience), we can proceed with the proper winding. We have:

Current density, 1,500

Area of bars, $\frac{200}{1{,}500}$ ...	=	·1333 sq in.
Depth of bar	...	·5 inch.
Width of bar $\frac{{\cdot}1333}{{\cdot}5}$ ...	=	·2666 inch.
Minimum of gauge of strips	=	·036 inch.
Say seven strips, each ·038 ...	=	·266 inch.

Bars.—The bar will now be built up as follows:—

Copper, width	=	·266 inch.
Paper = 6 × ·003	=	·018 inch.
Insulation ·02 × 2	=	·040 inch.
Width of bar ...	=	·324 inch.

Also

Copper, depth	=	·500 inch.
Insulation	=	·040 inch.
Depth of bar ...	=	·54 inch.

Air-Gap.—

Depth of two bars	=	1·08 inch.
Insulation on core = ·05 × 2	=	·10 inch.
Wire bands and mica = ·065 × 2	=	·13 inch.
Clearance $\frac{1}{8}$ inch all round ...	=	·25 inch.
Total air-gap ...	=	1·56 inch.

(*To be continued.*)

ACCUMULATOR TRACTION.

By R. KENNEDY.

Prof. Ayrton, in his remarks on this subject in criticising Mr. Epstein's paper, gives a table on p. 860, No. 1,047, December 17th, 1897, of the Electrical Review, which would have been of great value had another column, giving the rate of discharge per pound of plates, or, better still, per pound of positive plates, at which the watt-hours capacity per pound gross was obtained for the last column.

For the purpose of the worthy Professor the table is all that is required, and his allowance of nine watt-hours per pound of battery is a very generous one considering all things. But that table, like many others given regarding storage batteries, is apt to be used by other people for other purposes, which the addition of a column of rate of discharge per pound of plates would have effectually defeated. Further, it ought to be pointed out that the results of tests on a 7-plate cell cannot be compared with the results of tests on a 17-plate cell; the table shows this clearly.

It is high time for electrical engineers to agree upon some orderly method of tabulating battery performances; at present complete chaos exists, so that fair comparisons are impossible. In any case the watt-hours discharge per pound must always be taken, with the rate of discharge per pound, and the cells compared must be of nearly the same rate of amperes discharge. If these two simple precautions are omitted the figures are valueless for comparative purposes.

The mean P.D. is not a matter of much importance, as in most cells it makes little difference in the total watt-hours whether it is 1·9 or 1·8, or even 1·7 volts; but it makes a vast difference if one cell is discharged at 0·75 amperes and another at 1·0 per pound of plates.

CORRESPONDENCE.

A Defence of Germany.

I regret to notice in No. 1,048 of the Electrical Review, under "Notes," a rambling rhapsodical recitation: "A Daniel come to Judgment," launched against the head of a neighbouring and friendly nation, against a Sovereign just as highly esteemed in Germany as Her Gracious Majesty Queen Victoria is in Great Britain and Ireland. If such contributions were the reciprocal effusion of bad temper, they might perhaps be explainable; but Germans have never gone so far, and a feeling of international decency will always prevent them from personal insults of other nation's monarchical personages.

It would be the proper thing to ignore similar productions, if they were not the outcome of a widespread contagious disease, which threatens in England to assume an alarmingly dangerous character. What must be the standard of mind of authors who produce such discord-sowing rhapsodies! Do they really dream for a moment that their assaults would change the conduct of the performers of their imaginary or wilfully distorted complaints. Certainly such assumption would be ridiculous, especially in a country whose educational standard is continuously and emphatically recommended for emulation, by the highest statesmen in England, such as by Lord Rosebery at Colchester, by the Marquis of Salisbury's nephew, Mr. Balfour, at Sheffield; by Mr. W. Woodall, M.P., and Imperial counsellor of technical education; by Mr. A. J. Mundella, M.P., at Birmingham; Sir A. Arnold, President of the London County Council; Mr. John Morley, M.P.; Sir Henry Roscoe, and the Duke of Devonshire; Lord Playfair, writer, politician, and M.P.; Mr. Doxford, M.P., one of the most celebrated ship-builders; also recommended at the opening of the Davy-Faraday Research Laboratory by the Prince of Wales (the laboratory is a present of the value of £100,000 gratuitously given to the English nation by the German chemist, Dr. Ludwig Mond); as also recommended by many others, including even Mr. H. M. Stanley, M.P., of "dark country" fame; the press, as for instance, the *Daily Telegraph*, of November 20th of last year, and "last, but not least," by the *Board of Trade Journal* in the December number of the same year.

What then could such discord-hunting epistles aim at? Do they intend to hit German self-esteem and national enviousness, or do they perhaps wish to contribute to a desired change in the new course of national economy and commercial policy in Germany in favour of English interests? I can assure you most emphatically that neither one nor the other could be attained by any such chauvinistic writing. The German people, who read English papers very much indeed, are by this time fully accustomed to see through the coarse meshes of clumsily distorted misrepresentations. They recognise at the bottom, under the sieve, the real motive of the outburst, which is always the result of some political or commercial disappointment, which could not be helped, and they look at it, to say the least, with equanimity and smilingly.

With regard to the new course of German commercial policy, no light-handed talking could have the slightest effect upon it, as it not even depends upon the wish nor the will of the nation, but is forced upon the country and laid down by the inflexible laws of nature. On this point, and with the hearty desire to arrive to a mutual understanding, I beg you to grant a German with 25 years' residence in England a few more words.

The greatest modern politician of Great Britain, Joseph Chamberlain, expressed at the Birmingham Chamber of Commerce, if not in exactly the same words, but as near as I can repeat them, the following doctrine: "The culminating point of governmental triumph consists in the extension and security of commerce. One must, however, never forget that other nations have the same desire as we in England, and that the demand of Germany, France, and Russia for colonial extension must be principally attributed to the longing for buying, selling and profiting!" In these few sentences the experienced politician and shrewd business man laid down the principle of policy of civilised nations, the fulcrum upon which all business and political transactions now-a-days are supported. Another great Englishman of the present day, the Viscount Wolseley, has said: "Cosmopolitanism is the excrescence of an unhealthy civilisation, and the product of a senseless and unpatriotic philosophy."

These dogmas, although recently uttered, are not at all new; in fact, one might say they were recognised and religiously followed in England since 300 years. They were the prime motor during the long and destructive wars against the Spaniards, Dutch and French; they achieved the exclusion of the German Hansa, destroyed armadas and empires, which even in those days were more extended than the British Empire of to-day. The same political dogma, with the help of German troops and the timely arrival of Blucher, crushed at Waterloo the ambition of Napoleon, who craved to dispute the supremacy of English commerce at sea. If this supremacy, since the accession of Queen Elizabeth, was not always the primary cause of English wars, it certainly was always the leading principle in concluding peace. England, by these principles, and the political testament of Elizabeth—"to be friends with all, and allied with nobody," became a self-relying, commercial and naval nation of the very first rank. It is, therefore, perhaps natural, that this supremacy at sea, and of commerce, supported by an enormous accumulation of wealth, should have created a national feeling, that a monopoly of commerce and a claim on any part of the globe, not yet included in the sphere of civilised nations, should fall to Great Britain as an inheritance of priority, there we arrive at the foundation of all the evil!

"*Tempora mutantur et nos mutamur in illis.*" During the centuries when England was fighting for the supremacy of commerce, Germany was involved in mighty continental disturbances, of which the 30 years' war, which reduced the population from 25 millions to 12 millions, threw the country into exhaustion and internal disorder, and it took all the time till the reign of the Emperor William I. to strengthen the shattered race and reunite the Empire. With a population of 30 millions, as Germany had in the year 1830, it was quite rational, to be principally an agrarian country, the competition in North American and British-Colonial agricultural products not yet existing. But the German population having now risen to 54 millions, with a yearly increase of 670,000 inhabitants, and after American and British-Colonial products have ruined German agriculture, the law of self-preservation has forced Germany, *nolens volens*, to cease being an agricultural country, but to enter the rank and file of industrial competitors, which, in due course, and in strict accordance with the Chamberlain dogma, led Germany to colonial and sea power. Thus, German increase of population, North American and British agricultural competition forced Germany to become a competitor of industrial, commercial, and colonial England. No light-handed grumbling about imagined interferences with rights, which have no legal standing, nor any amount of national outburst of bad temper could change the logical sequences of Nature's laws. There are only two alternatives for England to meet the altered state of things, viz., either to destroy by force of arms half of the German population, its industry and commerce, and thus to reduce the empire to its former state of under-population and disorder; or, to accept the altered state of international position, and to undertake, shoulder to shoulder with Germany and with all other competing nations, the peaceful development of civilisation and culture of industry and commerce. Fortunately there is still plenty of room for all of us in many foreign lands! Although Germany is fully prepared for any attempt in the direction of the first alternative, everybody in the country is most heartily wishing for the latter, and the sooner such also becomes recognised in England the better for general peace, and for the welfare of the world.

Only a few words more about the fallacy of chauvinistic literature. Your correspondent suggested to the head of the German Empire, "to purchase for a few marks some patent or other from one of his *starving subjects*," evidently endeavouring, and perhaps succeeding, to make his countrymen believe that German industry and trade are in a starving condition.

Now, then, sir, as starvation and emigration always go side by side, let us look at the figures of emigration in Germany and in England. As long as Germany was principally an agrarian state, the annual emigration reached a few hundred thousand; thus the year 1882 still showed 220,902 German emigrants. From that year, and hand in hand with the development of German industry and commerce, the emigration gradually dwindled down, till it reached, in the year 1896, the insignificant figure of 33,824; and this in spite of an increase of population of 6,944,000 during that period of 14 years. The statistics of English emigration, on the other hand, show quite a different picture. England, including Scotland and Ireland, with a much smaller population than Germany, always showed a larger emigration, which amounted to a yearly average of 256,726 persons during the eightieth years, and rather increased during the later period, shewing 271,772 emigrants during the year 1895. I leave it to the judgment of the impartial reader on which side starvation is most likely to be; anyhow, it does not seem to be on the German side.

Hoping that these lines might contribute somehow to a better mutual understanding with regard to the inflexible laws of international and political economy and to smoothing existing friction.

R. von Fischer-Treuenfeld.

Dresden, *December 28th*, 1897.

Dust Destructors.

Mr. Raworth's letter on the subject of the Shoreditch Dust Destructors is opportune, as hitherto there has not been much point in the arguments advanced. But he fails entirely to appreciate the question, which, to those of us who are looking on, is at issue in this connection. We are not wanting simply to be told that, providing the extra capital expenditure does not exceed a limit, a combined dust destruction and electric lighting station is an economical undertaking. This we can pre-determine with fair accuracy for ourselves.

What we *do* want to know is the actual practical value of the method of thermal storage in use? This, for us, is what is under trial at the Shoreditch station. Mr. Raworth's diagrams and arguments ignore this question of storage altogether; and, therefore, although by contrast so clearly and vigorously expressed, they are really beside the question.

Is the thermal storage effective for the purpose for which it was designed? The fact that some coal is already necessary, although the station is but lightly loaded electrically, while supplied with its full quota of refuse, in the absence of other information, affords reasonable excuse for doubt that it is. Either the storage capacity is too small, or the practical thermal efficiency of the plant is extremely low. Imagine balance-sheets of two instances, the one as at Shoreditch, the other similar in every respect, except that the thermal storage paraphernalia is absent. On the debit sides are the total calorific values of all the available refuse of the parish, and that of certain quantities of coal; on the credit sides are the electrical outputs. Question: would the Shoreditch balance-sheet show any substantial advantage over the other? and if so, is it sufficient to justify the extra capital charges incurred on the storage plant?

Now, it is scarcely reasonable to expect Mr. Kershaw to decide technical points of this nature; rather it is for the designers and contractors to take up the challenge that has been thrown down, and to give figures to show that the innovations they have introduced have proved a success. If they can it is in their interest to do so; but are they not very agreeably surprised by the somewhat mistaken view of the Shoreditch scheme that has been taken by the public in general, and Lord Kelvin in particular?

It must not be forgotten that Shoreditch is not the first district in which the heat of dust destruction has been utilised for the purposes of electrical supply. It is simply the first of such undertakings in which thermal storage has been attempted.

It is very clear, nowadays, that unless some really effective system of storage can be devised, the advantages derivable from the combination of these essentially antagonistic processes of dust destruction and electricity generation, cannot be of attractive dimensions, and they have an unpleasant habit of vanishing altogether when put to the practical test. There are several methods of storage, the three most direct and obvious are:—

1. Storage of refuse, and the provision of means by which it can be burnt at any desired rate.
2. Storage of heat.
3. Storage of electricity.

Two years ago the Battersea Vestry invited schemes for the utilisation of the waste heat of their dust destructors in connection with electric lighting. As one of the competitors, I proposed a rather fanciful system of storing the heat, by means of regenerative stoves of brickwork. As an alternative, I outlined a scheme of refuse storage, in which I have still much faith. The time allowed for this competition was much too short, otherwise it might have been productive of some useful and interesting proposals.

The third method, storage of electricity, is rather under a cloud, because of the poor results at St. Pancras. But has it had a fair trial? Its great advantage is the way it economises boilers and generating plant, and in this way it partially balances the extra capital expended on the batteries. I am much inclined to prophesy that eventually the Shoreditch plant will be worked wholly on this method.

James Whitcher, A.Inst.E.E.

New Thermal Ampere-meter.

Referring to a note in your last issue on a new thermal ampere-meter, the following remarks may be of some interest:—

Many years ago, in 1881 and 1882, I experimented with several forms of instrument on much the same principle as that described in your note. In some, the bulb of an ordinary thermometer was closely surrounded by a conductor heated by the current to be measured, in others the bulb was forked, and the current, or a derivation from it, passed up one leg and down the other.

The object was to provide a means of measurement for alternating currents. A sliding scale, calibrated by means of continuous currents, was used, the zero of the scale being made to correspond with the height of the thermometer before the current was applied. Several of these instruments were useful at the time, but I did not consider them as practical for ordinary use, partly as being very delicate and of limited range, but chiefly because their indications depended, to some extent, on the conditions as regards the radiation and convection of heat from them.

I therefore much preferred the principle of the voltmeter, which has since become well known, in which the wire heated by the current is entirely enclosed within a thin tube of an equal coefficient of expansion to which the wire is fixed, so that the expansion measured is not absolute, but relative to the enclosing tube, to which all the heat generated in the wire must pass.

Thus the instrument reads the difference of temperature between the wire and the tube. I consider this principle very important for accuracy in any instrument depending upon the expansion of a conductor heated by an electric current.

P. Cardew.

Localising Faults in Submarine Cables.

The following, read in conjunction with Mr. H. C. Cann's communication, published in your issue of December 18th, 1896, may prove of use to some of your readers.

Modification of the Kennelly break test:—

The battery to be grouped in certain determined ratios, such as 1—2—4, or 1—4—16; if the former, we shall have from the rule of inverse square roots the resistance of the exposed end, as 1, 0·696, 0·485.

Measurements to cable current zero, and zinc to line. When measuring with the intermediate and lowest powers, insert in the battery circuit a resistance equivalent to the difference between the internal resistance of the cells in use, and that of the total, or greatest number; then it will be found that X = A — 4·75 (B—C).

The measurements, A, B, C, as usual, A being that obtained with the lowest power. For breaks close to the observer, the above will be found to give excellent results.

A few examples.

Break at 10 ohms distant.

Grouping of cells, 16—8—4. I.R. of battery 48 ohms.

100/100 zinc to line, measurements to cable current zero:—

C = 25 ohms.
B = 33 ohms (24 added to battery cct.)
A = 48 ohms (36 " ")
∴ X = A—4·75 (B—C) = 48—38 = 10 ohms.

Ditto at 20 ohms.

C = 35
B = 43 (add as above).
A = 57 (" ") X = 57—38 = 19 ohms.

Ditto at 30 ohms.

C = 44
B = 52 (add as above)
A = 69 (" ") X = 69—38 = 31 ohms.

Ditto at 40 ohms.

C = 55
B = 63 (add as above)
A = 78 (" ") X = 78—38 = 40 ohms.

Ditto at 50 ohms.

C = 67
B = 75 (add as above)
A = 90 (" ") X = 90—38 = 52 ohms.

Break at 80 ohms.

C = 96
B = 105 (24 added to battery cct.)
A = 123 (" ")
X = 123—42·75 = 80·25 ohms.

Ditto at 100 ohms.

C = 117
B = 125 (added as above).
A = 138 (" ")
X = 138—38 = 100 ohms.

Ditto at 150 ohms.

C = 170
B = 180 (added as above).
A = 197 (" ")
X = 197—47·5 = 149·5 ohms.

Ditto at 500 ohms.

C = 522
B = 235 (added as above).
A = 562 (" ")
X = 562—61·75 = 500·25 ohms.

Ditto at 1,000 ohms.

C = 1,050
B = 1,070 X = 1,100—95 = 1,005 ohms.
A = 1,100

Break at 20 ohms.
Another set, bridge 100/10. I.R. 44 ohms.

C = 273
B = 302 (add to battery cct. 22 ohms)
A = 350 (" " " 35 ")
X = 350 — 137·75 = 212·25 = 21·22 ohms.

Break at 45 ohms. 100/100.

C = 51
B = 62 (add as above)
A = 72 (" ")
X = 72 — 28·5 = 43·5 ohms.

Ditto. ditto. 100/10.

C = 534
B = 568 (add as above)
A = 638 (" ")
X = 638 — 161·5 = 476·5 = 47·65 ohms.

Break at 20 ohms.
I.R. 16 minottos = 162 ohms. Bridge 100/10.

C = 365
B = 450 (added to battery cct. 81 ohms)
A 590 (" " " 120 ")
X = 590 – 4·75 (450 – 365) = 18·6 ohms.

Break at 500 ohms.

C = 5,250
B = 5,380 (added as above)
A = 5,580 (" ")
X = 5,580—4·75 (5,380 – 5,250) = 496·2 ohms.

John McGill.

Alexandria, Egypt, *December 22nd*, 1897.

Shoreditch and its Dust Destructor.

My attention having been called to the letter in your last week's issue signed "Power," and having also read the two letters in this week's issue signed by Mr. Raworth and Mr. F. W. Brookman—although, as I have already stated, it was not my intention to continue a newspaper correspondence with anonymous letter writers—I feel that, as the two letters in this week's issue are signed by gentlemen who show their *bona fides* by writing over their own names, I must, in courtesy, reply, as far as I am able, to the position of the Shoreditch destructor as they put it.

I must thank Mr. Raworth, whose acquaintance I have not had the pleasure of making, for his very lucid letter, which shows that, in contradistinction to your anonymous correspondents, he has at least grasped the reasons that have induced the Shoreditch Vestry to embark on this undertaking, and realises the certainty of their making some profit out of the combination which must, at least, be worth the having, whilst it may result in savings of a most considerable nature.

Referring to the remarks that appear over the *nom de plume* of "Power" once again, and to the general tone of the correspondence of this gentleman, "X. Y. Z.," and "Anti-Humbug," and likewise to the position you yourselves have thought fit to assume in this matter, I wish to protest in the most emphatic manner against the false impressions that are being disseminated amongst those who may be interested in adopting such a combination as we have, and who are more than likely to assume by you and your unknown correspondents' attitude that the allegations of deception and fraud so constantly reiterated by you and your anonymous friends must of necessity have some justifications in fact.

My Vestry have entered upon an experiment which they were led to believe would save them in the expense both of the disposing of their ash-bin refuse and in the production of electricity for the supply of their parish, and if these two hopes are realised, as they bid fair to, then they will have achieved all they hoped to do.

As you are well aware, quite recently attempts have been made in two London districts to effect the same object, with signal failure in both cases. By this I mean that in neither case has the refuse destructor been of any practical use in the generation of electricity in the electric light stations erected in proximity to these two dust destructors.

As I have constantly reiterated, so far the electricity supply in Shoreditch has been maintained by the combustion of the refuse, only excepting on those occasions when there has been no refuse to burn; and every fair-minded man holding unprejudiced views cannot but admit that the efforts of my Vestry have already resulted in turning into a not inconsiderable success that which has been attempted previously by others without success, and therefore some credit is due to us and our engineers for a pioneer effort in the direction of the utilisation of a waste product, even though it may be possible that in the future plant may be designed which may give better results than the first successful combination of the kind.

To read your own remarks and those of your anonymous correspondents, one would almost imagine that your journal had changed hands and is now being controlled by some journal having antagonistic interests to the advancement of electrical industries. I should myself have thought that your journal would have been the first to have congratulated us on the undoubted success we have met with, instead of doing all in your power and in that of your anonymous correspondents to make it appear that not only is the undertaking not a success, but that fraudulent means have been adopted to make it appear so.

I note, indeed, that you say "And if the first twelve months' work show that their combined scheme of dust destruction and electricity is successful we shall be the first to acknowledge it." Would it not have been fairer and in every respect more desirable—assuming you really had any desire to see the success of an electrical scheme, such as this, involving substantial progress—if you had left your remarks unsaid until such time as the works publish their first accounts, and then, and then only, used the influence and power of your journal to criticise it unfavourably, if it so deserved, than to endeavour to hound it down at this moment so as to discredit it in the eyes of others, who must undoubtedly be influenced by the erroneous view you take of the matter, and who, unfortunately, are hardly likely to notice those few words in which you may in the future acknowledge that you were mistaken in your previous impressions so continuously and emphatically reiterated in your paper from week to week by the shamefaced utterances of anonymous correspondents?

As an example of the way in which you and your correspondents endeavour to turn an easily explainable fact into a proof of the justness of your and their remarks, one cannot do better than read that portion of "Power's" letter in your issue of last week, in which he refers to the letter of the "Engineer in charge of the Dust Destructor, Shoreditch," to the *City Press* of August 11th, stating that "It is the fact that coal was used on the opening day, but that because we had no refuse, and therefore had to burn coal to generate the steam required," and in reference to which "Power" goes on to state that Lord Kelvin said dust only was used, while the engineer says that they had no refuse, but burnt coal to generate the steam, and that therefore Lord Kelvin was not in the coal secret, and ending up by inferring that a lie was told the assembled company in stating that the current was generated from dust, and dust only.

Now, Mr. Editor, what were the facts. The current during the morning and the afternoon was generated entirely by ash-bin refuse as stated, and would have continued to have been generated by ash-bin refuse throughout the night, had it not been that the Vestry had a parade of their dust carts in connection with the opening ceremony, as you yourself must have seen when you were there, and which naturally resulted in the dustmen not collecting any further refuse with contradictions, and are strangely out of agreement with each other. Having shunted the dispute once to the popular issue of hours, he does not find this to work, so he has tried to shunt on to an attack upon unionism. But his own friends have found him out, and we scarcely think that the A.S.E. is going to get its further funds for fighting, unless it be from Germany or America.

Additional Premises.—Owing to the increased business, Mr. F. C. Allsop has had to take large new additional premises at 126, Queen Victoria Street.

Business Announcement.—Messrs. Handley & Shanks have opened new offices and showrooms at 12, Dawson Street, Dublin. Mr. Arthur Handley, A.I.E.E., will act as manager for Dublin and neighbourhood. The firm undertakes all classes of electrical work, including town and private lighting, and transmission of power. They are carrying out important contracts for the principal railway companies in Ireland.

Calendars, &c.—Messrs. W. H. Willcox & Co., send us an 1898 Date Remembrancer, having a detachable sheet for each month.

We have also received, as usual, one of the E.P.S. Company's very useful blotting pads, with almanack for 1898, memoranda book, &c., attached, and some general information regarding the company's batteries. We believe there are many electrical men who, like ourselves, find these pads very serviceable.

Messrs. Hasel, Watson & Viney are sending out the seventeenth edition of the Hardware Trade Diary and Cash Book to the subscribers to the *Hardware Trade Journal*, in accordance with usual custom. This volume, we have no doubt, is welcomed by that class of business men for which it is intended, and particularly to those having to make a good number of cash entries every day. The book is ruled cash throughout, with the exception of a few memoranda pages, and there is half a page set apart for each day. All the pages are interleaved with blotting paper.

The Brockie-Pell Arc Lamp Company send out a handy pocket-card, with revolving arrangement, by means of which dates for any day up to 1903 may be ascertained.

Messrs. Jackson & Coleby, electrical engineers, of Thayer Street, W., have issued an 1898 calendar with a sheet for each month.

Messrs. Hodges & Todd, of Hampstead Road, N.W., have brought out a very neat and well printed calendar. There is a sheet for each month, and each sheet has a complete calendar for the year. This firm reports with regard to the business of last year that, notwithstanding the serious labour troubles, they have had a very successful year. Their trade in large switchboard and central station requirements has been quite unprecedented, whilst the demand for ammeters and voltmeters, together with their specialities in high tension apparatus, has been far ahead of previous years. During the year they have extended operations by opening premises in George Street, and cabinet works in Seaton Street, to cope with the large increase of trade.

Catalogue.—Messrs. W. M. Still & Co., of Charles Street, Hatton Garden, have compiled a new catalogue. Among a host of general brass and copper fittings for a variety of purposes, we observe stamped ornamental switch bases, or feet, for floor lamps, brass and copper art fittings, electric globe carriers, counterweights and pulleys, reflectors, switch covers, bell pushes, and numerous electrical accessories. There are further various artistic designs of coronets for arc lamps, the Still incandescent lamp, &c. The catalogue, which contains over 150 pages, and is well studded with illustrations, is bound in stiff green covers.

Changes of Address.—Mr. A. A. Crawford (The Bombay Electric Company), of Bombay, announces that owing to increased business, he has taken more extensive business premises at No. 9, Meadow Street, Bombay, where letters should now be addressed. The workshops are also being extended.

Owing to 19, Great George Street being required for the site of the New Government Offices, Edmundson's Electricity Corporation, Limited, have removed their offices to Broad Sanctuary Chambers, Westminster.

Messrs. Handcock & Dykes are removing from 5, Victoria Street, S.W., on January 29th, to Westminster Chambers, 1, Victoria Street, S.W.

Dissolution of Partnerships.—Messrs. Henry Lea and W. H. Thornbery, carrying on business as consulting engineers at Bennett's Hill, Birmingham, as Henry Lea & Thornbery, have dissolved partnership. The business will be continued by Mr. Henry Lea and his son, Mr. F. M. Lea, under the style of Henry Lea & Son. See our "Official Notices" for further particulars.

Messrs. C. F. Slater, S. R. Slater, and F. Crossley, manufacturers of surgical appliances and electrical apparatus, and manufacturing electricians, of 20, Baker Street, Portman Square, trading as Slater, Bros. & Crossley, have dissolved partnership. Debts will be attended to by C. F. & S. R. Slater.

Liquidation Notices.—A general meeting of the Acme and Immisch Electric Works, Limited, will be held on February 4th, at 3 o'clock, for receiving an account of the winding up from the liquidators, Messrs. E. Wilding and J. Gray.

Partnership Notice.—We are informed that Messrs. S. V. Clirehugh & F. A. Cortez Leigh have entered into partnership with Mr. E. M. Lacey, A.M.Inst.C.E., and Mr. A. M. Sillar, M.Inst.E.E. The title of the firm will now be Lacey, Clirehugh & Sillar, and the offices will henceforth be situated at 78, King Street, Manchester, and at 10, Delahay Street, Westminster. Each partner will, as heretofore, give personal attention to the work on which he is at present engaged. The notice we have received does not make it quite clear whether Mr. Cortez Leigh is included in the arrangement. His name is printed at the top of the printed circular, so we assume he is a partner.

Change of Name.—We are asked to state that the name of the firm of Venner & Sillar, of Delahay Street, has been changed to Venner & Co.

Electrical and General Engineering Company.—This company informs us that the electric lighting of Wellington Hotel, Tunbridge Wells, to which we referred recently, is being carried out by them; and they have also carried out other private installations in that town, including "Firmount." The same company has recently completed the wiring of Collins's Music Hall, having installed the equivalent of 3,000 8-C.P. lamps in a month. Among other contracts now in hand are mentioned installations for the Canterbury Arms, Brixton (including engine and dynamo), various City hotels, the Synagogue, St. John's Wood, the new Synagogue, Great St. Helen's, St. Swithin's Church, Wesleyan Chapel, East Road, &c.

Electrical Engineering in Italy.—A company has just been formed at Florence, with a capital of £80,000, to be known as La Società Toscana per Impresi Elettriche, to establish an electricity generating and distributing station in that city. It is said that Messrs. Schuckert & Co., of Nuremberg, Germany, are interested in the new undertaking.

Electrical Engineering in Germany.—Large new works for the manufacture of electric cables are about to be established at Spandau by Messrs. Siemens & Halske, of Berlin.

Gas.—A gas explosion, which occurred at Leicester on Saturday night last, did a great deal of damage to property. A nurse was thrown violently against the wall and killed on the spot.

Harrison & O'Brien.—This firm, owing to increased business, have removed their offices and testing department from Albany Buildings, 45, Victoria Street, Westminster, to 19 and 21, Queen Victoria Street, E.C. At their new address they are increasing the size of their laboratory and testing department, and will now be able to undertake all classes of work in that line, in addition to out-door testing and inspecting.

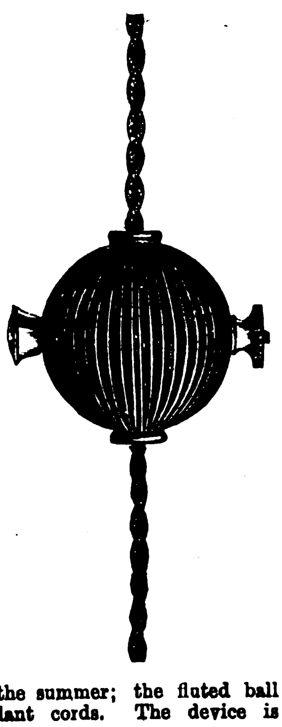
New Firm.—We are informed that Mr. J. Foxcroft and Mr. W. J. V. Duncan, late of the firm of Paterson & Cooper, Dalston, have started in business as electrical and mechanical engineers, at 24, Queen's Road, Dalston, where they propose manufacturing arc lamps, switchboards, indicators, &c. We understand that Mr. Foxcroft has had large experience in the manufacture of such goods, having been foreman and manufacturing contractor with the firm mentioned for 20 years.

New Journal.—We have received a copy of No. 1, December, 1897, of a new paper known as the *Journal of Acetylene Gas Lighting*. The journal will be published monthly from 13, Farringdon Avenue, London, E.C. The first number contains, among other items, an introductory article by Prof. Vivian B. Lewes, and "Some Notes on Acetylene" by Hiram S. Maxim.

New Premises.—Mr. Albert C. Hands announces that he has taken showrooms recently occupied by Messrs. Winfield, Limited, at 39, Snow Hill, E.C. Mr. S. Croneen, late of Winfield's, Limited, and Mr. G. Boorman, will represent the firm jointly in London and suburbs, and the country ground will be covered as usual by Messrs. A. C. & G. Hands. Mr. Hands has arranged a partnership with Mr. Harold Davis, of Star Works, Stafford Street, Birmingham.

Refuse Destructors.—Messrs. E. Green & Son, Limited, have received instructions to supply one of their economisers to the Shoreditch Vestry electric light and destructor works. We understand their apparatus is already used with highly satisfactory results at several other destructor plants, including Oldham and Winchester.

Regulating the Height of Incandescent Lamps.—Messrs. Chas. Joyner & Co., Limited, of Icknield Square, Birmingham, are just putting on the market a little contrivance to provide a simple and inexpensive means for altering the height of incandescent lamps without the need of counterweights. The firm is hoping that the device will supersede the unsightly method of looping and knotting flexible cords now used to shorten incandescent leads, which we illustrate herewith. A fluted ball divided into two halves forms the cover to a small reel upon which the flexible cord is wound by turning the fixed nut on the one side. This nut is serrated, so that when the lock-nut on the other side of the ball is screwed up tight the projections on the lock-nut engage in the grooves of the fluted cover and thus prevent the reel turning further. There are two types of this fitting made, one to be fitted up whilst the installation is being erected, and the other a pattern which can be applied to existing lamps by slipping sideways on the flexible cord. The advantages claimed for this device are: it is cheaper and more sightly than counterweights; the best height for the lamps can be found experimentally without knotting cords or breaking connections; the lamps can be wound up to the ceiling if not required in the summer; the fluted ball forms an ornament to plain pendant cords. The device is provisionally protected.



Reported Amalgamation.—It is stated from London, says the *Newcastle Daily Leader*, that the well-known firm of Easton, Anderson & Goolden, Limited, engineers and millwrights, of the Thames Ironworks, Erith, Kent, and Palace Chambers, Westminster, London, S.W., have amalgamated with Sir W. G. Armstrong, Whitworth, & Co. Messrs. Easton, Anderson & Goolden are at present engaged in substituting electric for hydraulic lifts on the Electric Railway, Stockwell and London Bridge, in addition to important contracts for Woolwich Arsenal.

Ryman v. Salmony & Co.—In our recent report of this case heard at the Westminster County Court, we stated that judgment was given for the plaintiffs for the balance of £8 10s. This, we are informed, should be 8s. 10d., which was for postage account. The only business done and paid for was £190 10s. 9d.

The Aston Lamp-Holder.—We illustrate below this new lamp-holder, which is being put before the electrical trade by Messrs. Veritys, Limited. It is claimed that the holder will meet with commendation from the fact that it possesses in a marked manner the two essential features of an ideal lamp-holder—small size and high insulating properties. With respect to the former characteristic, the "case" is $\frac{3}{8}$-inch shorter than that of the ordinary lamp-holder, while a neat and symmetrical outline has been preserved; as to insulation, the holder is provided with a new interior (M. B. Cotterell's Patent), which we illustrate. Fig. 1 shows the "base" end, and Fig. 2, the "lamp" end. Some of the strong points claimed by Messrs. Verity are that (1) Absolutely no metal of either conductor is exposed at the base end of the insulator. The fear of short-circuiting through one conductor being pinched down on to a terminal or plate of opposite polarity is thus altogether avoided. (2) The end of the insulator exposed to the lamp is of solid china, the two plungers alone protruding. Here, again, a short-circuit cannot occur under ordinary circumstances. (3) The chief danger in block terminal insulators is that a strand of flexible or other wire, by protruding too far through

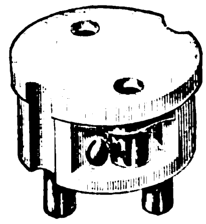


Fig. 1.

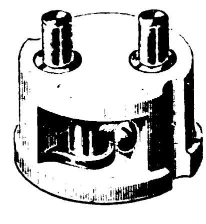

Fig. 2.

the terminal, is liable to short-circuit on to the other pole. In Cotterell's patent interior this is impossible, as the wire can only be passed a slight distance through the terminal. (4) The manner in which the metal parts carrying current of opposite polarity are separated leaves nothing to be desired as to insulating properties. The construction of the interior renders this holder admittedly suitable for use on 220 volt circuits, or even at higher E.M.F. Further, it is extremely easy to wire; its construction is simple; and, although its insulation is so high, the size of the holder is small, being that known as the dwarf type. We have before us a sample of this lamp-holder, and it is excellently made and finished off—in fact, it is one of the best we have seen.

1897.—Messrs. Geipel & Lange, in sending notes of last year's operations, report that the business in Geipel's steam trap or automatic drain cock has increased rapidly during the year, particularly with respect to the electricity supply stations. At present upwards of 40 stations, have adopted these traps, which have already been described in our columns. This trap is also being largely adopted in the States, in Europe, and in the Colonies, for pressures up to 300 lbs. per square inch, while it was awarded the gold medal at the Brussels Exhibition. The manufacture of these traps continues in the hands of the Shillingford Works Company; but on and after January 1st, the sales will be conducted entirely through Messrs. Geipel & Lange, of 68, Victoria Street, Westminster, S.W. During the past year the Westminster business of Messrs. Paterson & Cooper has been sold to Messrs. Geipel and Lange, and notwithstanding the transfer, their staff are stated to have been fully employed. Amongst work which they have carried out during the year, is the complete equipment of the Kennington Road Baths, the new Royal baths at Harrogate, the Church Missionary Society's premises in Salisbury Square, Lambert & Butler's new factory and offices in Drury Lane, Emanuel & Co.'s new premises, Fore Street, Public Market Hall, Harrogate, Dr. Palmer's new house in Queen Anne Street, &c. Messrs. Geipel and Lange have been appointed agents for Messrs. T. Richardson & Sons, of Hartlepool, for the Brown-Boveri power transmission plant, and by Messrs. Ganz and Co. for the Blathy alternate current meters, &c.

ELECTRIC LIGHTING NOTES.

Aberdeen.—Mr. Smith, gas manager, and Mr. Blackman, electrical engineer, have reported to the Gas and Electric Lighting Committee that additional motive power will be required at the electric station in view of the extension of the system. The lighting of the quays from the corporation mains will considerably increase the pressure on the plant, which even now is occasionally very heavy. The engines at present in the station have an aggregate of fully 1,000 H.P., and the committee is to invite tenders for an additional engine of from 600 to 700 H.P.

There is a proposal to light the streets with electricity where electric mains are available, and to light all other streets with incandescent gas lamps.

Belfast.—The Electric Committee report that the new station buildings are now progressing satisfactorily. The contractors expect to have completed the first section of the work by the middle of February, and soon after that the committee hope to be in a position to supply current. The Council has approved of the adoption of Wright's system of charging for electric current from July 1st next. The committee also desire authority to supply and let on hire motors, for which they propose to charge a rental of 15 per cent. on cost to cover interest, sinking fund, and depreciation.

The Council had a brief discussion regarding several increases which it is proposed to make in certain officials' salaries. Mr. V. M'Cowen, the Corporation electrical engineer, was spoken of in very high terms by several members, one speaker saying that he had saved the city at least £3,000 in the drawing up of plans and other matters in connection with the electric light station.

Bexhill.—There will be a Local Government Board inquiry on 12th inst. in reference to the Council's proposed £20,000 loan for electric lighting.

that day after the early morning, and as we have not yet solved the problem of raising steam without either refuse or coal, we were under the necessity of continuing with coal, when the refuse was completely burnt out, for the rest of that evening.

Referring now to Mr. Brookman's letter, I would again point out to you the damage that is occasioned by you and your anonymous correspondents' erroneous expressions, as is exemplified therein, for Mr. Brookman, who writes most fairly on the subject, states in his letter "As to anyone being ashamed of Shoreditch, I give the chairman credit for having done his best, and no one can do more, and that being so there is no need for shame, even if the scheme was an absolute failure, which cannot be said of Shoreditch *I think*." From which it is evident that he too has been misled by you into believing that there is certainly a taint of failure about the Shoreditch scheme, for he evidently is not quite sure but that it may possibly be a complete failure.

The destructor works being still under the guarantee of the contractors for this portion of the work, it is impossible for me, without violating my position as chairman of the Electric Light Committee, to give Mr. Brookman such answers to his questions as might place the Vestry in a false position with their contractors, especially seeing that Mr. Brookman, at the time when the contract for the said works was being settled, approached the Vestry as representing or assisting one of the competing contractors who did not obtain the work, and I would, therefore, ask him to wait for an answer to most of his questions until we are able to answer them authoritatively without prejudice to the contract, and would further point out to him that the total number of units sold as against the actual refuse burnt, could convey no conclusions to his mind, since the number of units that was sold from the combustion of that amount of refuse, although very considerable, does not represent the number of units that could be sold from the combustion of this amount of refuse, if the output demanded a further supply. I can, however, answer his question as to the size of the accumulator battery we have installed. It is only proportioned to give an output of 25 kw. during the hours of maximum load, and is therefore not a material help at that time, but is rather intended to provide an unfailing source of current whence to magnetise the fields of the various generators.

I therefore ask Mr. Brookman, and all the many readers of your Journal who may have been misled by the misstatements you and your anonymous correspondents have so consistently made, and which I am powerless to contradict while the matter remains still *sub judice*, to wait until that time when our first year's running accounts are published, as they will doubtless all perceive that the proof of the pudding is in the eating, and not in the interested remarks of anonymous correspondents (competing dust destructor manufacturers, coal merchants, dust removal contractors, &c.), or the opinions of editors of journals, who have no practical experience of the subjects about which they write.

H. E. Kershaw.

129, Curtain Road,
Shoreditch, *January 3rd*, 1898.

[We must protest strongly against Mr. Kershaw's allegations that we have suggested, or even hinted at, there being deception and fraud going on at Shoreditch, and we much prefer that in future he should deal with our comments separately and not recklessly mix them with what our correspondents, who are well able to take care of themselves, have said. Our own remarks were based solely upon Mr. Kershaw's official statement as chairman of the Electricity Committee, and it seems to us that this worthy gentleman himself would have been better advised had *he* refrained from giving figures until the works' accounts were out, unless he were content that they should be criticised. It is important to observe that though Mr. Kershaw has given certain "official figures" regarding the dust destructors, he objects to give more on account of "the destructor works being still under the guarantee of the contractors." As to the few words at the end of our amiable correspondent's letter, we are content to rest in the knowledge that he is not in a position to judge.—Eds. Elec. Rev.]

THE ENGINEERS' STRIKE.

When the late Conference was proposed, the men's executive professed themselves most anxious to hold it, and the Employers' Federation came in for a good deal of abuse for not running hastily to it. It was generally understood that the two sides at the Conference would come to certain agreements which would be endorsed by their respective supporters. On the side of the men, however, while agreeing to things at the Conference, their representatives have practically told the men not to endorse their action. Below we print a statement of Col. Dyer's, made on behalf of the Employers' Federation:—

"The conditions of freedom to the employers in the management of their works, which was one of the subjects before the recent Conference, are not merely proposals of the employers, but were agreed to by the representatives of the allied unions, who introduced some modifications of the original terms to safeguard the position of the unions. It is also highly significant that the leaders of the allied trades offered that their men would return to work on the following Monday under these conditions of management, provided the employers would agree to a 51 hours' week.

"This offer conclusively proves that these conditions are not in any way incompatible with the proper functions of trade unions. The federated employers have resolved to adhere to them in future. The federated employers have repeatedly declared that they cannot agree to any reduction of hours, and nothing has occurred to alter their decision. No prolongation of the dispute can, therefore, affect their position with regard to the conditions of freedom in the management of their works and the hours of labour.

"Under these circumstances, the federated employers invite the serious attention of the workmen concerned to the fact that these conditions of management will afford an opportunity to the individual workmen to earn much higher wages, that any man desiring to improve his position will have opportunities of acquiring greater skill, and that every man will have the right to bring any grievances to the direct notice of his employer, either individually or through his union. It does not appear that these advantages were brought before the notice of the workmen, nor that it was pointed out to them that there is no intention of imposing novel conditions, or of reducing the rates of wages paid to skilled men; but that the freedom which the workmen enjoy in many of the federated workshops is to be extended to all of them.

"The Federation hope that the time is not far distant when the workmen will appreciate the goodwill of their employers, and will frankly accept the situation by withdrawing their demands for a diminution of the working hours, and by accepting the conditions of management agreed upon at the Westminster Conference, which closed on December 17th.

"(Signed) Henry C. S. Dyer, President."

We would draw special attention to the fact that the conditions as to non-interference were agreed to, and that this is not considered incompatible with trade union interests. The hours question is thus alone nominally standing in the way.

At the time of writing, December 31st, there is in the immediate future the alternate prospect of a spread of the lockout, which, indeed, has, we believe, already taken place by the posting of the hitherto Conference delayed notices, or of the opening of their works to such of the men as choose to return to work on the basis of the agreement come to at the Conference. We hope this latter course will be the one adopted. It would show the employers determination to adhere to the terms they had agreed to, and it would enable many men to return to work who are anxious to do so. The strike will go on, we suppose, all the same. It will become a sort of academic institution. Like some of the City Guilds which have long since lost all touch with the originating cause, the strike may continue drawing funds from America and Germany for an indefinite period. But that, as a practical fact, the strike will go on, we hardly believe. It was bound to fail, being started on a false basis. By Mr. Barnes's own confession, the quarrel was shunted from interference with shop management and the machine question, to the "popular one of the eight hours' day," and the trick failed to gull the public at large.

That curious body, the Fabian Society, compounded of snuff-clothed dramatic critics and æsthetic dames with its pseudo socialism and general dilettantism, has at this late hour given mouth on the question in the shape of a manifesto in favour of the strikers, gratuitously and ignorantly assuming that the desire of employers to use machinery is merely an attempt to reduce a prosperous trade to the level of a sweated one, where collective bargaining has not yet been introduced. Absolute ignorance is all we can say to such drivel. There is no desire to interfere with the proper duties of trades unionism, nor would there have been any move in the direction of complaint about the minimum wage had the A.S.E. done its duty, and seen to it that its members for whom it asked a minimum wage were all competent men. But everyone knows that large numbers of the A.S.E. are not good men. It is a blunder on the part of the A.S.E, for which history will record its sentence, to have allowed itself to be dragged out of its proper path. But the powerful desire to get up a fight has been the dominating factor; funds must be raked in, and men who have had no claims to be called engineers, have been admitted to membership for the sake of funds. It is not trades unionism that is at stake in any sense. It is simply the policy of Barnes or of those who have pushed Barnes into the van, that is now being tried and found wanting. This is the vampire that has sucked the vitals of unionism, and through unionism of English trade. All suffer by it, from Col. Dyer to the last new apprentice.

We confess to sharing the doubts recently expressed in an able article in *Engineering* that much of the freedom allowed for in the sounding clauses agreed to at the Conference amounts to really nothing. Freedom to employ any man is one of these; freedom to be a trades unionist is another. According as a shop falls under the head of union or non-union, so far will certain unwritten laws tend to prevail. The whole thing is a matter of common sense and the application of knowledge of facts. If men would do a fair day's work, their nursing by the trades union would do no harm. Probably the average workman needs some such backset. But he is unfortunately ordered by his executive to do certain things in the way of loafing which he is told are for his good. He has done as he was told, and has simply succeeded in proving to the world that apprentices and labourers can turn out more work than he has been doing. But this is not trade unionism. It is want of knowledge. If the secretary of the A.S.E. had been a man of better education and of observant travelled experience and with a knowledge of commercial facts, he would have carried on the business of the A S.E. in a very different manner, and would have succeeded in getting for his members better pay. We fancy we see Col. Dyer receiving a notice some morning that "he is paying his men too little, and compelling them to the monotony of attending to two machines while capable and desirous of having three." This is the sort of thing a really live and up-to-date secretary of the A.S E. would see to. But we cannot learn that there has ever been anything but restriction; we cannot hear that there has been for many years the slightest attempt to secure that its members were ordinary decent tradesmen and reputable citizens. We do not learn that they have ever taken cognisance of any complaint made against their members for notorious laziness. We hear of no single case of any willingness to render possible the taking of some big contract by agreeing to the *status quo* of wages pending its completion, or of any case of a willingness to work with an employer for the common good. One thing is very certain. Machinery in the end is bound to win. This does not imply that the human workers will lose, or how is it that in the chain trade, to which machinery is so little applicable, the human element is so badly paid? Machinery will win and the skilled tradesman—the fitter—will be so scarce in time that when needed he will command good pay. Skill will consist in an ability to compel so many machines to do so much work, and the old seven years or five years apprenticeships will die out. A machine can be learned quickly. Boys will earn more than they did, and the family man will be sooner relieved of his expenses. The fact has got to be faced. The whole system has got to be changed, and it is scarcely likely that the country will go out of trade to suit minds of the quality Mr. Barnes seems to consider as above the average, to wit, his own (*vide* speech at Enfield). Failing to secure the modern methods forced on her by foreign competition, England will have to go out of trade, but England has no intention of going out of business, and the sooner this fact is realised the better it will be for all who are pursuing an *ignis fatuus*. Workmen have so often claimed that all wealth is the outcome of labour that one marvels to see them demanding conditions that could only be granted them if wealth were other than the product of labour. But the mere manual labourer, working by the strength of his muscles, or with the experienced collaboration of hand and eye, would never produce a fraction of the wealth he is able to produce in conjunction with the brain worker, and the brain worker is entitled to some of the wealth he helps to produce. The present demands of the manual worker amount to a claim by him that he is competent to perform both the manual and the brain work, for if the performance of a machine is to be restrained at the desire of the labourer, why not the whole system of book-keeping, supply, purchase, sales, and finance. If we go to the full end of this line of argument we should find ourselves compelled to place the general-managership of all England in the hands of the coal hewers, who alone are at the root of all power. The A.S.E. are very keen to grasp the duties of those above them, but they are jealous to a fault when those below them, or even on a par with them, interfere with their privileges or encroach upon fields they consider to be their own. Labour can only be turned to wealth by the touch of management, and to interfere with management will be fatal to success. Management may not always be successful. When otherwise it brings its own punishment very quickly. To force trades union ideas of restriction upon management would ruin everything. If it be good to work any machine below its capacity, then must it be good to work it not at all, or at least to build cheaper machines good enough only for the reduced capacity. Backwardation of this stamp would quickly bring us back to the time of no machinery. Trades unionists would not acknowledge that this is what they are aiming at, but if they do not it is because they have not sufficient perspicacity to see to the end of the lane they are following. Neither do they seem to perceive that in stopping production they are reducing the power of the nation to pay them wages. England without work would be a sorry place to live in until the production of its own soil was equal to the demands of its population. It is fortunate that the number of men now idle bears so small a ratio to those at work, and we might remind trades unionists that the other business of the country, when it wants the production of engineers, will not come to a stop because such productions are not to be had of English make. They will simply purchase them from abroad.

In view of what he considers the failure of Unionism, Mr. Tom Mann now proposes that Unionism should be national, and provide its members with simply idle pay, strike pay and funeral expenses, but the old, infirm, or sick will have no claim. Practically, Mr. Mann's proposals amount to the recruiting of a mere fighting army which will bury its dead We do not think that he will find many decent workmen to join his new army. That there is something wrong with Unionism we admit with Mr. Mann himself, but we cannot but smile when Mann says so. It is calm in the very eye of a cyclone, the apparent *fons et origo malis.* Looked on as a cyclonic movement, trades unionism is equally calm in its centre of disturbance, but Mr. Mann is not on strike pay. He can be calm, but he is now feeling anxious for the men to get back to work, for if they are idle much longer, where are the funds to come from wherewith poor Tom struggles so bravely along?

On Friday last the Fairfield Company of Govan posted lock-out notices, which will affect about a thousand members of the A.S.E. The Fairfield Company seems only to have come into line because they are persuaded of the necessity of doing so, for they have stood out of the Federation a long time.

It is reported from Yarrow's Yard that cylinders are now being bored out in three days less time than before the strike. The secretary of the Free Labour Association states that the Association has provided 22,000 men during the strike, of whom no fewer than 8,500 are at work in London alone. We are sorry to learn that the Free Labour Association refuse to entertain men who have been members of the A.S.E. who wish to leave the A.S.E. and get back to work. There must be many who wish to do this, and it is pitiable to think of the straits to which these men and their families are reduced by the long idleness.

The engineering employers of Leeds are responsible for the following statements as to the conditions prevailing in Belgium, where the hours of labour range from 60 to 66 per week.

In Liege, the wages for 60 hours per week for fitters are 18s. 4d. to 22s. 6d.; turners, 18s. 4d. to 28s. 9d.; machinemen, 13s. 9d. to 18s. 4d. At Antwerp, the wages are:—Fitters, 21s. 3d. to 26s. 3d.; turners, 21s. 3d. to 26s. 3d.; machinemen, 18s. 4d. to 18s. 9d. *Overtime counts after 12 hours.* The Clyde wages for 54 hours are for fitters, turners, and machinemen, from 25s. to 35s.

English workmen should endeavour to bring up the European Continent to English levels. Comparing foreign with English wages, it is not possible to urge that the foreigner puts up with less money because his living expenses are less, for it costs more to live there than in England, the purchasing power of money being much more in England than it is abroad.

It is undesirable that English wages should be reduced. Reduced wages only mean a smaller volume of home trade. The endeavour should be to increase the output of the country. It is only by output that England can live, but one has only to refer to the case of Thomas Parker, Limited, reported on page 933 of our last issue, to see how output is deliberately curtailed by unprincipled unionists.

The Trades Union Congress of Saturday last does not help to clear the atmosphere. Confusion of issues is more confounded than ever. Mr. Barnes, who has agreed to certain things at the Conference, and offered to send the men back to work if the 51 hours' week was accepted by the employers, loudly states that the men will fight on until 48 hours is won. But men outside the A S.E., who spoke at the Congress of Saturday, stigmatise the terms of the employers as ridiculous, and as an attempt to destroy trades unionism altogether. Yet Messrs. Sellicks and Barnes agreed to these very terms. Indeed, here is an abstract of their circular to the men:—

"These proposals differ somewhat from those submitted before, and they secure the status of the unions on some of the points covered. . . . . The right of the unions to collective bargaining on behalf of their members is maintained. . . . . On the whole the proposals, as set out, do, to some extent, risk your interests, but your delegates ventured to offer on your behalf a return to work on the basis of a 51 hours' week, which, however, the employers declined."

Clearly if the employers had only acceded to a 51 hours' week, the risk hinted at would have been taken. Clearly a matter of three hours a week cannot make all the difference between smashing and preserving the principles of unionism. On the other hand, it may be argued that the employers, on their side, are not merely concerned with the demand for eight hours. If it had not been for the trades unions themselves, and their restrictions on output, we should have had the eight hours long ago. The employers undoubtedly are fighting for the right to run their machinery under its best and most economical conditions. They object to the eight hours because they want to be first very sure they have got the upper hand in the output question before they risk curtailment of hours. Neither the men nor the masters are really so interested in the hours question as they themselves believe. As regards the men, such of these in London as are in eight-hour shops still come up from their suburban homes by the same trains as formerly. If offered to start work at 8 a.m. only, and with one break per day, they will grumble because they must still come early to save the workman's trains. The employers do not really care so much about the eight hours, and are really fighting for infinitely more than the few hours. From 9 to 8 hours is only about 12½ per cent; but between the A.S.E. loafing rates and cuts and decent work there is anything from 25 to 400 per cent. Of what concern is a paltry six hours in comparison with this? Mr. Barnes at the congress made the usual charges against the employers as the cause of all the suffering, and as disturbers of the peace. Knowing that the lockout would follow on the strike for eight hours, one can only, in a sense, admire the brass of the man who can so deliberately travesty facts. There was a good deal of discord at the congress, and it is curious to note that the money to be collected by the suggested weekly levy on all unionists is to be distributed by the Parliamentary Committee, not by the A.S.E. It seems clear that the A.S.E. is out of favour, the general body of trades unionists resenting the autocratic behaviour of that section. The above 3d. levy was estimated to produce £12,000 a week, which is more than Mr. Barnes asked for. But there seems a doubt as to its forthcoming. He referred to the men having been existing for six months on 7s. to 16s. a week. "God only knew how they did it." Mr. Barnes, if he has the strength of mind to cut down his own diet below the scale of the Westminster Palace Hotel, might try it on for himself for a month. He would learn, then, how they did it, and in the future he would, perhaps, be a little more careful how he led his fellow men into such positions.

Mr. Barnes talks too much by far. His policy is not trusted by other unionists, and is, there seems but little doubt, responsible for the sad condition of the engineers to-day. His speeches teem and also for the purpose of extending the area within which the current can be supplied, have resolved upon the Stuart Street site. It is intended to convey the current from this generating station to convenient sub-stations situated in various parts of the city. A deputation will interview the several local authorities through which the existing tramcar service runs in reference to the Manchester Corporation supplying electric traction beyond the limits of the city. The Town Clerk is to report as to the steps to be taken for acquiring the lines belonging to the Manchester Carriage and Tramways Company within the city.

Motor Vans.—The borough engineer of Wolverhampton, Mr. Bradley, has issued the particulars of the motor vans required by the Wolverhampton Corporation.

Nottingham.—It is understood that a sub-committee of the Tramway Committee is considering what is the best system of traction to be adopted for the tramways instead of horses.

Proposed Electric Railway.—A Bill "for incorporating the City and Brixton Railway Company, and for empowering them to construct an underground railway from the City and South London Railway to Brixton Hill," has been deposited for next Session. The proposed railway, which will be nearly 3⅜ miles in length, will commence by a junction with the City and South London line under the High Street, Borough, and will terminate under Brixton Hill. In connection with the railway it is proposed to widen the City and South London line near London Bridge Railway Station, and also to construct a railway connecting with the Kennington Oval Station of that line. The capital required by the proposed company is £1,200,000, with power to raise a further sum of £400,000 by the creation of debenture stock. The Bill also seeks power to enable the company to acquire by purchase or lease so much of the existing City and South London Railway as lies between their proposed point of junction in the Borough and King William Street in the City.

Proposed Electric Railway from Charing Cross to Paddington.—A Bill to incorporate a company for the purpose of constructing an underground electric railway from Charing Cross to Paddington has been deposited at the Private Bill Office. The proposed railway will commence, says the *Times*, to the north of the Avenue Theatre, at the southern end of Northumberland Avenue, and will terminate on the south side of James Street, near Paddington Station. In connection with this railway it is proposed to construct a subway to the Great Western Railway Company's Paddington Station and another subway to Albert Terrace, Knightsbridge. The capital required for this scheme is £1,500,000, which is to be divided into 150,000 shares of £10 each, with the power to divide them subsequently into "preferred half-shares" and "deferred half-shares." Upon this capital it is proposed to raise a further sum of £500,000 by the creation of debenture stock. The time stated for the completion of the line is five years, during which period it is proposed to pay interest out of capital to an amount not exceeding £70,000. The Bill proposes to authorise the company to enter into agreements with the Great Western and South Eastern Railways. The promoters of the scheme are Sir George Russell, Mr. Henry Cosmo Orme Bonsor, and the Hon. Alfred E. Gathorne-Hardy, who, with "four other duly qualified persons to be nominated by them," are to be the first directors of the company.

St. Helens.—Dr. Hopkinson has submitted his report to the Gas and Lighting Committee with respect to the introduction of electrical traction upon the tramways. He advises that no further extension of the electricity works be made pending the completion of the works for supplying the energy for traction, the committee in the meantime putting up with the risks of any inconvenience that might arise. The committee has resolved that the question of the extension of the present plant be postponed, and that only such additions to the undertaking as may be absolutely necessary be made for the present. It was further resolved that the present machinery for the electric supply of the Town Hall be left in such a condition, that if the necessity should arise, the Town Hall and the Gamble Institute may be connected therewith.

TELEGRAPH AND TELEPHONE NOTES.

Delays in Australian Telegrams.—During the progress of the cricket match played at Melbourne this week, we find among the items of cricket news in the evening papers the following paragraph:—"There has been considerable delay in the transmission of our special cables to-day, and Dalziel's agency is informed by the Eastern Telegraph Company that this is due to irregularity in the working of the land-lines in Australia." As we have previously pointed out, the relation between cricket and telegraphy is not at once apparent; but thanks to the keen general interest felt in the former, the public is enabled to get some insight into the deficiencies of the latter. A business man must needs tolerate in disgust and silence, an inconvenience which those interested in sport would not think of suffering for a moment. In spite of the airy protestations of the Postmaster-General of South Australia, who assures the London Chamber of Commerce in reply to a protest made by them—that the Australian land-lines are rarely interrupted—we find on looking into the matter that during the past year, at the very lowest computation, there have been seven occasions on which the failure of these lines have been sufficiently marked to call for notice in the Australian press. Although in January last the interruption on the South Australian land-line lasted about four days; and although the interruption to the same line last month continued for about four or five days, still we are supposed to derive complete consolation and conviction from an official assurance that such things rarely or never occur, and are not to be anticipated in the future; so thus in dealing with any proposal to furnish a trustworthy means of telegraphic communication with Australia, we are to consider that cause of complaint as regards the existing lines is, officially, a myth! We use the word officially, of set purpose, as in spite of the fact that the various Australian provinces have, officially, bound themselves (with, perhaps, the exception of Queensland), to report any such interruptions to the International Telegraph Bureau at Berne, yet they fail to keep their bargain; and even when specifically challenged by the London Chamber of Commerce, one of the more prominent of these Postmasters satisfies himself by writing an explanation, which cannot possibly satisfy anybody else who knows the truth of the case.

Huddersfield Telephones.—The Huddersfield Chamber of Commerce had a discussion on 31st ult. *re* municipalisation of telephones.

Middlesbrough Telephones.—The Streets Committee has considered the unsatisfactory state of the telephone service in the town, and has resolved to ask the Mutual Telephone Company, of Manchester, who are desirous of extending their services to Middlesbrough, their terms for connecting all the municipal offices in the town.

Pacific Cable.—Sir Sandford Fleming, in a communication made to the Press, urges the Government of Canada once more to take up the project for a Pacific cable. He argues that the proposal of the Eastern Extension Company, which resulted in the suspension of the Pacific cable project at the last conference, would not adequately fulfil the purpose, what is required being an auxiliary system free from liability to interruption. He declares that the Pacific cable scheme was pronounced impracticable, expensive, and in the interests of the Eastern Extension Company only. The Australasian Colonies being politically disunited, Sir Sandford Fleming holds that it behoves Canada to make definite proposals, for which the mother country is waiting: "If we are to be brought within speaking distance of kindred communities in the Southern Seas," he concludes, "the first impulse must come from ourselves."

Telegraph Delays.—A deputation from the Liverpool Chamber of Commerce waited upon the Postmaster-General on 29th ult. for the purpose of complaining of the delays in the transmission of telegrams between Liverpool and the Continent. Mr. P. E. Hemelryk asked the Postmaster-General to urge the French and German Governments to expedite matters on their side. The Duke of Norfolk promised to give the various points raised his most careful consideration, and undertook that a new duplex wire should be made available between Liverpool and Hamburg. He also held out a hope that telephonic communication would, if it were found practicable, be established between Liverpool and Havre.

Telegraph Rates for the West Indies.—The West India and Panama Telegraph Company and associated companies have determined to apply from 1st inst. a large reduction in rates between Europe and Jamaica. The reduction amounts to 2s. 10d. per word between Europe and Jamaica, or from 5s. 10d. to 3s. per word. The same reduction will be extended to the West India and Panama Company's stations east of Jamaica, and will also include Demerara. The tariff with the French Islands of Guadeloupe and Martinique will, however, it is understood, for the present remain without alteration.

Telegraphists' Grievances.—The executive committee of the London branch of the Postal Telegraph Clerks' Association have prepared a list of the grievances of which they complain, and will publish them in the form of a manifesto.

The American Pacific Cable Company.—The Pacific Cable Company, of New York, met some weeks ago and elected the following directorate:—J. Pierpont Morgan, Edmund L. Bayliss, J. Kennedy Tod, Rear Admiral John Irwin, U.S. Navy, and James A.

Scrymser. Mr. Scrymser was elected president, and Mr. Edmund L. Bayliss vice-president and acting treasurer. The company announces that the surveys for the cable between the coast of California and the Hawaiian Islands are highly satisfactory, and that arrangements are being made for the establishment of that section within 18 months. It will require over 9,000 miles of cable to connect the United States with the Hawiian Islands, Japan, China, and Australasia. The proposed Pacific cable between America and Hawaii will be up before Congress this session. A Bill was introduced in the 54th Congress authorising the Pacific Cable Company, of New York, to lay this cable. After being reported favourably by the Committee on Commerce in the House, it was sent to the Postmaster-General for a report. This report has not as yet been given out, but, according to the New York *Electrical Engineer*, it is said will be presented to Congress soon after it assembles. Mr. Edmund L. Bayliss, vice-president of the company, states that the Government had completed a survey of the route as far as the Hawaiian Islands, and if the Bill passed at the coming session the cable would be in running order in 1898.

CONTRACTS OPEN AND CLOSED.

OPEN.

Bilbao.—February 28th. The Secretary of State for Foreign Affairs has received a despatch from Her Majesty's Consul at Bilbao, reporting that the provisional board appointed in connection with the electric tramway which it is proposed to lay from Zumarraga to Zumaya, in the province of Guipuzcoa, invite plans and tenders, to be received by February 28th, for the construction and equipment of the line. Further particulars of the conditions of the tenders for the above-named tram line and branch, which together measure 30 miles, may be inspected at the Commercial Department of the Foreign Office any day between the hours of 11 and 6.

Bedford.—January 10th, 1898. The Electric Light Committee want tenders for the supply and erection of a 420 B.H.P. double-acting compound enclosed engine, and a 250-unit alternator with stationary armature. See our "Official Notices" December 10th for particulars.

Bootle.—January 10th, 1898. The Corporation wants tenders for the supply and erection of boilers, engines, dynamos, switchboard, pumps, transformers, wiring, alteration of Town Hall wiring, batteries, mains, street boxes, and the running of the electricity works for three years. Consulting engineer, Mr. T. L. Miller, 7, Tower Buildings, Water Street, Liverpool. See our "Official Notices" December 10th for further particulars.

Bradford.—January 13th. The Corporation are asking for tenders for two steam engines for their electricity works at Valley Road. Further details will be obtained from our "Official Notices."

Bedford.—January 24th. The Corporation want tenders for the supply and delivery of vulcanised rubber cables. See our "Official Notices" this week.

Blackburn.—January 22nd. The Corporation want tenders for a 500-kw. continuous current steam dynamo, and a 120-kw. steam alternator. Consulting engineer, Mr. E. M. Lacey. See our "Official Notices" this week.

France.—January 22nd. The Municipal Authorities of Neuilly-sur-Seine are inviting tenders for the concession for the establishment and working of a central electric station in the town. Particulars from, and tenders to, La Mairie de Neuilly-sur Seine.

Gloucester.—January 18th. The Electricity Committee want tenders for boilers, dynamos, overhead crane, switchboard, accumulators, mains, arc lamps, meters, &c., for electric lighting. Consulting engineer, Mr. Robert Hammond. See our "Official Notices" December 10th.

Guernsey.—Tenders are wanted for the States of Guernsey for the supply of several hundred creosoted telegraph poles, ranging from 22 to 60 feet. Particulars from Mr. A. R. Bennett, 44, Manor Park Road, Harlesden, London.

Guipuzcoa.—February 28th. The Secretary of State for Foreign Affairs has received a despatch from Her Majesty's Consul at Bilbao, reporting that the provisional board appointed in connection with the electric tramway, which it is proposed to lay from Zumarraga to Zumaya, in the province of Guipuzcoa, invite plans and tender, to be received by February 28th, for the construction and equipment of the line. Further particulars of the conditions of the tenders for the above-named tramline and branch, which together measure 30 miles, may be inspected at the Commercial Department of the Foreign Office between 11 and 6.

Leicester.—January 31st. The Leicester Corporation invites designs and tender for motor vehicles for the collection of house refuse. Specifications and particulars, with drawings, to be sent to the Chairman of the Sanitary Committee, to the office of Mr. E. Geo. Mawbey, C.E., borough engineer, Town Hall, Leicester.

Newport.—January 24th. The Electricity Committee want tenders for the supply and erection of mains, transformers, switch gear, cast-iron posts and for arc lamps. Consulting engineer, Mr. Robert Hammond. See our "Official Notices."

Roumania.—March 15th. Tenders are being invited by the General Direction of the Roumanian Post and Telegraphs in Bucharest for the supply of 56,000 metres of galvanised iron and steel wire.

Shoreditch.—January 11th. The Vestry want tenders for wiring materials for one year. Particulars can be seen at the Lighting Engineer's Office, Town Hall.

Spain.—January 9th. The municipal authorities of Torrente (Valencia province) are inviting tenders for the concession for the electric lighting of the town during a period of 17 years. Tenders to be sent to El Secretario del Ayuntamiento de Torrente (Valencia).

Tunis.—Tenders are at present being invited (no date being mentioned) by the Société Immobilière d'Hamman-lif, near Tunis, for the construction of an electric tramway, about 10 miles long, between Tunis, Maxula-Rades and Hamman-lif.

CLOSED.

Bo'ness.—The contract for the whole of the electrical equipment of the Bo'ness Docks has been given to the Brush Electrical Engineering Company.

FORTHCOMING EVENTS.

1898.

Saturday, January 8th, at 3 o'clock.—Royal Institution of Great Britain. Sixth (concluding) juvenile lecture on "The Principles of the Electric Telegraph," by Prof. Oliver Lodge. Subject:—"Space Telegraphy."

Monday, January 10th.—Northern Society of Electrical Engineers, Palatine Hotel, Manchester, at 8 o'clock. Presidential Address by Mr. Raworth.

Tuesday, January 11th, at 8 p.m.—The Institution of Civil Engineers. Paper to be read with a view to discussion:—"The Machinery used in the Manufacture of Cordite." By E. W. Anderson, Assoc.M.Inst.C.E. Monthly ballot.

Röntgen Society. General meeting at 11, Chandos Street, Cavendish Square, W. Paper at 8.30 p.m. by W. Webster, F.C.S., "Practical Work with the X-rays."

Wednesday, January 12th, at 7 p.m.—Society of Arts. Second juvenile lecture, by W. Ramsay, Ph.D., F.R.S., on "Fire."

Thursday, January 13th, at 8 p.m.—The Institution of Electrical Engineers. Presentation of premiums. Inaugural address of the President, Joseph W. Swan, Esq., F.R.S.

Friday, January 14th, at 8 p.m.—Institution of Civil Engineers. Students' meeting. Paper to be read:—"Mechanical Draught." By R. Gordon Mackay, Stud.Inst.C.E. Sir Albert J. Durston, K.C.B., M.Inst.C.E., will preside.

NOTES.

Cable Factory Changes Hands.—We learn that the well-known cable factory of the Fowler-Waring Cables Company at North Woolwich has been acquired by the Western Electric Company, of 79, Coleman Street, London, E.C., Chicago, and Antwerp.

Personal.—On the recommendation of the Minister of Trade and of Posts and Telegraphs of France, the President of the Republic has promoted M. Léonard Raymond to the grade of Commander of the Légion d'Honneur. The Presidential decree describes M. Raymond as Administrator of Postes and Telegraphs, with 44 years of administrative service, and as Officer of the Légion d'Honneur since April 14th, 1876. M. Raymond represented the French Government at the International Telegraph Conference of Buda-Pesth in 1896, as chief of the delegation of that country, and won the sympathies of those who had not enjoyed the pleasure of his acquaintance previous to that meeting, and we are sure his numerous friends will rejoice at the distinction conferred on him by his country's Chief of the State.

Electrical Illuminations.—On New Year's Eve many public and private buildings in New York were decorated with strings of electric lights in honour of the extension of the City boundaries. At the stroke of midnight search lights were turned on the flagstaff at the City Hall. An electric current sent a furled flag to the top of the mast and unfurled it.

Blockley.—By means of public subscriptions this village is to be lighted with 28 electric lights, and Mr. H. N. Warburton, electrical engineer, has been instructed to proceed with the work.

Chelmsford.—Last week, Mr. A. H. Pott, representing the Chelmsford Electric Lighting Company, attended the district council meeting with reference to the company's application for a provisional order to extend their system to several villages in the neighbourhood of Chelmsford. The Council afterwards almost unanimously expressed the wish that the wires should be laid underground.

Croydon.—The Electric Lighting Committee, after conferring with Prof. Kennedy, recently advised the County Council to authorise the further extension of the plant by the provision of an additional unit consisting of an engine, alternator, and boiler (the same size as that at present on order), at a cost of £5,000. This was proposed in view of the increasing demand for current, and the length of time required to obtain new machinery. The extension was stated to be absolutely necessary, especially in view of the contemplated extensions to Norwood and Thornton Heath.

Darlington.—The Town Council is asking the Board of Trade to amend its 1890 electric lighting provisional order, so as to include the whole borough with the exception of Oxen-le-Fields.

Doncaster.—An application was recently made by Messrs. Fisher & Allison, electrical engineers, asking that the Corporation will give their consent to their supplying electric light to certain persons in the neighbourhood of their shop to the extent of not more than 4 horse-power. A committee recommended that consent be given only until the Corporation are able to supply electricity in the borough and subject to an agreement.

Dublin.—The *Daily Nation* has been endeavouring to interview several members and officials of the Corporation for the purpose of getting to know something regarding the future of the electric lighting undertaking, but none of these gentlemen are to be drawn.

The Dublin and Manchester Steamship Company have asked the Port and Docks Board for permission to erect poles in connection with a proposed installation of electric light at the place on Sir John's Quay where their steamers are to be berthed.

Eccles.—The Electric Lighting Committee have decided, subject to the approval of the Council, to let tenders for the electric lighting of the borough amounting to £9,392. This sum is £2,000 less than the amount sanctioned by the Local Government Board.

Germany.—The Municipal Authorities of Elberfeld have decided on the construction of a second central station in the west end of the town at an estimated cost of £125,000.

Gloucester.—The City Council has resolved to ask Mr. Hammond to meet the Electricity Committee to go into the question of site and give some information *re* the scheme.

Hammersmith.—On Wednesday the Vestry had before it the report of the Electric Lighting Committee with regard to tenders received.

Ipswich.—The Ipswich Board of Guardians have decided by 13 votes to 12 to adopt a system of electric lighting for the Union Workhouse.

The *East Anglian Daily Times*, in a leaderette regarding the matter, concludes as follows:—"Having worked with both gas and electric light we can have no hesitation as to their relative merits, and it would be difficult to find those who have worked by the new light wishing to return to the old."

Kendal.—A sub-committee recommends the appointment of Messrs. Handcock & Dykes, of London, as electrical engineers to report on electric lighting.

Kingston.—In a review of the year the *Surrey Times* says that the electric lighting business of the Corporation has during the year literally progressed by leaps and bounds, no less than 2,375 lamps having been installed, bringing up the total to 9,200, and a substantial profit on the year's working will certainly accrue.

Kintore.—Some days ago the electric light was introduced into the business premises and dwelling house of Mr. W. Hutchson, baker. The dynamo is driven by a powerful oil engine used in his bakehouse.

Lancaster.—Applications have been received for a supply of electricity to several premises in Moor Lane. The engineer is to canvass the neighbourhood in order to ascertain if others are likely to require a supply.

Leeds.—At a special meeting of the City Council, announced for Wednesday (5th inst.), a report was presented by the Parliamentary Committee respecting the proposed purchase of the undertaking of the Yorkshire House-to-House Electric Light Company. If the report was adopted it was proposed to apply forthwith to the Local Government Board for a provisional order to empower the Corporation to issue irredeemable and redeemable stock for the purpose of purchasing the undertaking.

It is stated that a sub-committee is to arrange a friendly conference with the Yorkshire House-to-House Electricity Company, Limited, in the course of the next few days, *re* the proposed purchase.

Lewisham.—The Lewisham District Board of Works have refused to give their consent to the applications of the Great Western Electric Light Company and the County of London and Brush Provincial Electric Light Company for provisional orders to supply electricity in the district.

Liverpool.—A deputation from the Tramways Committee recently waited upon the Lighting Committee with reference to the lighting by electricity of the experimental line of electric tramway. Central poles are to be placed in Prince's Avenue.

London.—At the Commission of Sewers' meeting on Tuesday, the Solicitor (Mr. Baylis) reported the result of the case in which the Commission was sued by the City of London Electric Lighting Company for the non-payment of a sum of £1,442 on an account for lighting the City. It was stated that it was remarked by the Judge that the Corporation should not have stopped the amount, but paid it, and then sued the company for it. Mr. Turner moved that the Solicitor should be instructed to recover the amount. This having been seconded, Mr. C. J. Harris moved, as an amendment, that the question should be referred to the Streets Committee with power to take the necessary steps. Mr. Tranter seconded the amendment, which was carried.

Llanidloes.—The electric light has been installed at the Railway Foundry by the enterprising proprietor, Mr. John Mills.

Manchester.—There is a feeling among some of the members of the Corporation that a grave error was committed when appointing the new Electricity Committee last November in a number of old members of that committee not being re-elected by the Corporation. It is held that the attendance of some or all of these gentlemen on the Electricity Committee is very necessary just now in view of the large extensions of the works and plant which are under consideration. A proposal dealing with the matter was to come before the Corporation on Wednesday, a resolution being placed on the agenda by Councillor Lambert adding the names of the six members who were omitted in November to the Electricity Committee as it now stands.

The Electricity Committee recommends the Council to purchase land in Stuart Street, Bradford, for the establishment of a new generating station. This step is deemed necessary in order to carry out the electrical working of tramways within the city, and to extend the area of electric lighting.

Middlesboro'.—At the last meeting of the Streets Committee, says a local paper, it was decided on the recommendation of the Electric Lighting Committee "that wherever the Streets Committee were laying down new streets they would put a 2-inch pipe, at the cost of the Electric Lighting Committee, through which to thread the electric wires."

Newcastle-on-Tyne.—The plans of Messrs. Lummis-Peterson & Co., for the electric lighting of Heaton Road Wesleyan Church has been accepted. Tenders were sent in by nine firms.

Peterborough.—An important point respecting the electric lighting question came up at the meeting of the Town Council on Tuesday last week. The Electric Extension Company, Limited, having made proposals for the transfer of the provisional order by the Corporation to such company, the Town Clerk was instructed to reply that whilst the reply of the Local Government Board was pending, the Council could not consider such proposal. At a subsequent meeting it was resolved that a letter be sent to the Board of Trade giving notice of opposition to the application for powers by the Peterborough Electric Light Company. The Town Clerk was instructed to again communicate with the Local Government Board urging that an inquiry into the matter of the application of the Council with respect to electric lighting might be held at an early date. With reference to previous correspondence on the subject of the system proposed to be adopted for the supply of energy under the Electric Lighting Order, 1894, the Secretary to the Board of Trade transmitted, for any observations the Corporation might wish to offer, a copy of a memorandum in the matter by Major Cardew, R.E., the electrical adviser to this department. The memorandum stated that with the proposed electrical pressure between the outer conductors it would be necessary that the intermediate conductor be maintained throughout at very nearly the potential of the earth. The simplest means of arranging for this was to connect this conductor with earth at the generating station, but at no other point; and the Board of Trade had in several cases provisionally approved of such connection under certain conditions. As the negative conductor of the proposed-bare copper mains would necessarily be maintained at a potential of 220 volts negative to earth, there would be a strong tendency to the occurrence of leakage at the insulators, involving possible dangers from electrolytic action, and should this system of mains be used, it would be necessary to provide for rigid inspection of all the insulators. The engineer, having had a consultation with Dr. Fleming, recommended that the following observations be forwarded: (1) If the electrical pressure of 440 volts between the outer conductors is adopted, the middle wire will be connected to earth at the generating station, but at no other point, and the undertakers will comply with any provisions or conditions the Board of Trade may desire. But in making application for permission to use 440 volts between the outer conductors, the undertakers wish to retain the power to use the lower pressure of 220 volts if it should be thought desirable; (2) the system of distribution proposed to be used is continuously-insulated mains, and the bare copper was only mentioned in case it might be considered desirable to use it at any special point. If any bare copper is used, such insulators and means of inspection will be provided as meet with the approval of the Board of Trade. The Town Clerk was instructed to forward these observations to the Board of Trade.—The Town Clerk read the following letter: "Local Government Board, Whitehall, S.W., December 23rd. Sir,—I am directed by the Local Government Board to advert to your letter of the 11th inst. relating to the application by the Town Council of Peterborough for sanction to borrow £15,000 for works of electric lighting, and I am to state that according to the latest information in the possession of the Board the Council's margin of borrowing powers is not sufficient to enable them to borrow the sum of £15,000 in addition to the sum of £4,500 for which they desire sanction to borrow for hospital purposes —I am, yours faithfully, A. D. Adrian, Assistant Secretary."—The matter came before a special Council meeting on Wednesday.

Power Distribution Scheme.—The Bill promoted by the General Power Distributing Company, for providing electric power in a 26 miles area was considered by the Council the other day, and it was resolved that the Bill be opposed, in conjunction with the other local authorities. The Nottingham City Council has appointed a strong committee to oppose the scheme.

Shoreditch.—The Lighting Committee has advised that the application of the County of London and Brush Electric Light Company for a way leave for cables in a direct line through, without supplying current in, the district of the Vestry, at a rent of £50 per annum, be not granted.

Swinton.—A Committee of the District Council is considering the question of electric lighting by a private company.

Torquay.—Under the direction of Mr. Storey, engineer-in-charge, the electric lighting works are being pushed forward. Two sets of machinery have been received, and all three boilers have been submitted to full steam pressure, the trials having proved in every way satisfactory. There are now 44 consumers on the mains, and 3,000 8-C.P. lamps have been placed in the residences and shops of the town. The streets will be lit by 57 arc lamps.

Tunbridge Wells.—It is proposed to accept the lowest tender sent in for building extensions to the electricity works, *i.e.*, that of Mr. W. J. Logan at £1,059.

Ventnor.—Mr. Pressland recently wrote on behalf of the Ventnor Electric Light and Power Company asking for the approval of the Council to the site for the station. The application was granted.

Walsall.—The Grand Theatre, Walsall, was lighted electrically on 22nd ult. for the first time. The stage is now illuminated by 170 electric lamps of various colours, which can be manipulated from a switchboard so arranged that the illumination can be red, green, or white at a moment's notice. The theatre itself is also now completely lighted with electricity.

Wednesbury.—The Council will oppose the application of the Midland Electric Corporation for a provisional order, it being considered that the work ought to be in its own hands.

West Hartlepool.—A Local Government Board inquiry was held last Tuesday *re* the Corporation's proposed £30,000 loan for electric lighting.

West Derby.—The Board of Guardians of the West Derby Union have instructed Mr. Thos. L. Miller, M.Inst.E.E., of Liverpool, to prepare full plans and specifications, and to invite tenders, for the lighting of their Mill Road Infirmary by electricity. The installation, we understand, is estimated to cost upwards of £5,000.

Westminster.—The Board of the Westminster Electric Supply Corporation, Limited, has decided to reduce the rate of charge for electric energy as follows:—From January 1st, 1898, the price charged for current used for lighting purposes will be at the standard rate of 6d. per Board of Trade unit for the first 4,000 units used in each year. All units used in each year in excess of 4,000 will be charged at the net rate of 4d. per unit. The price charged for current used solely for purposes other than lighting, and supplied through a separate meter, will be at the rate of 3d. per Board of Trade unit.

Wormit.—Inquiries are being made among the residents as to whether they are in favour of electricity, gas, or oil as an illuminant for the village. If two-thirds are in favour of electric lighting a detailed scheme will then be submitted to a public meeting.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

Blackpool.—The Tramway Committee, a short time ago, applied to the Local Government Board for permission to substitute the overhead trolley system for the conduit system of electric traction on the promenade. Not only has the board refused this permission, but it has condemned the existing conduit system as well. This has come as a surprise upon the committee, who are going to interview the officials in London on the matter. Meanwhile they have decided to lay a tramline through Claremont Park, instead of along the low promenade.

Bristol.—Last Saturday the Tramway Committee appointed to negotiate with the Bristol Tramways and Carriage Company for the purchase of the system, reported to the City Council that the company absolutely refused to negotiate, and were now promoting two Bills for extending the system.

Collision.—On 26th ult. an electric tram collided violently with a motor car at Haddington Road, Dublin. The ends of both cars were considerably damaged. The cause of the accident is believed to be the failure of the motor brake to act.

Croydon.—A correspondent of the *Bullionist*, referring to the proposed purchase of the Croydon Tramways Company's undertaking by the British Electric Traction Company, says that the terms of the sale are "manifestly unfair to the ordinary shareholders." The meeting, he says, was held with doors closed to the press, and he is taking steps to see whether it is too late to prevent the sale on the terms proposed.

A Norwood paper says that the tramways system has been taken over by the British Electric Traction Company, who will introduce electrically-driven cars, and Mr. H. A. Durke's services are retained for the management of the new company.

Derby.—The proposed purchase of the tramways by the Council has been making progress in the hands of a committee, and the company has intimated that it is prepared to negotiate for the sale of the undertaking. With a view to making an offer to the company, the committee propose that an engineer be employed to advise them on the matter. The question of electricity is being taken into account.

Dublin.—The extension of the United Tramway system which will connect Rathmines by direct route with the electric tram near Ballsbridge is being pushed forward energetically. Already a large portion of the line is laid down. The length of the new tram line will be close on 2½ miles. The effect of the new line will be to connect the extremities of the southern townships from the eastern side of Rathmines Township at Haroldscross to the Pembroke Township at Ballsbridge, and thence near Haddington Road with Sandymount. The entire work is being carried out by the United Tramway Company's own men, who have laid the rails.

Light Railways.—The proposal of the British Electric Traction Company to construct light railways in the Fenton District is not to be opposed by the Fenton Council.

The proposals to construct light railways between Highgate and Finchley, and Finchley and Hendon, were before the Finchley District Council last week. Mr. Vesey Knox, M.P., barrister, appeared on behalf of the electric scheme, and submitted that the system proposed—overhead electric trolley—was the only one possible for such a rural district, and if there was a fatal objection to the system, that would be fatal to the scheme. They proposed to light the road along the line of route at a price to be agreed upon with the Council; a quick service to Hampstead, and, consequently, a service to the West-end of London and an additional local service to the Great Northern Railway. Owing to the provisions of the Tramways Acts, they proposed a street traction far superior to any existing in this country at present; fares of 1d. per mile (but anticipated four miles for 3d.); the average speed (time table), eight miles throughout, was proposed; repair of 18 inches on each side of the lines, which meant where double lines existed 16 feet; the posts would be of an ornamental character, on one side of the road only; purchase by the local authority at the end of 35 years. The only object they had in going under the Light Railways Act was to save the expense of a Parliamentary Bill. They intended putting on a special service for the working classes. They had power to carry goods, but the passenger traffic was looked to; they did not intend to combine goods and passenger cars.

Lucan Tramways.—The Lucan Steam Tram Company are, says *Freeman's Journal*, at present in communication with the Board of Trade with reference to the inspection of the line from the Conyngham Road to Leixlip. It is expected that the inspection will shortly be made, and that the line will soon afterwards be open for traffic. The line has been completely relaid, new rails put down, and the gauge has been widened from the former one of 3 feet to 3 feet 6 inches. The cost of re-sinking the line is nearly £16,000. The remaking was undertaken with a special view to the line being worked by electricity, and provision has been made for the ultimate carrying out of that intention. The introduction of electricity for traction purposes will involve an additional outlay of about £15,000. Until that work may be undertaken, the line will be worked by steam. It is estimated that the conversion of the line, as it is now constructed, into an electrically equipped line, will be carried out in four months, and that change will involve a stoppage of the traffic for that length of time. The board of directors are in negotiation with a London firm of contractors for this work, and if there is a prospect of the work being completed by the summer, it will be commenced as soon as the contract is signed. Otherwise the summer traffic will be carried on by the steam haulage, and the electrical equipment will be postponed until the close of the summer season. The trams with the steam haulage will run every hour, and with electric traction they will be run every half hour. The system of electric traction to be adopted is the trolley overhead wire. The power house will be erected about midway on the line, near St. Lawrence's Road. The dynamos will be driven entirely by steam, as the board has been advised that the water power would not be sufficient. When the contract is completed, the building of the power house will be first commenced.

Manchester.—The Special Committee of Tramways appointed by the Corporation recently resolved: "That the electrical equipment and the supply of the electric current necessary for the working of the tramways of the Corporation within the city be placed in the hands of the Electricity Committee, and that they be requested to take the necessary steps for the carrying out of the work; the terms of payment for the current to be supplied to be hereafter arranged." The Electricity Committee, with a view to carrying out this resolution,

The Northern Society of Electrical Engineers.—Notice is given that a special general meeting of the members of this society will be held at the Palatine Hotel, Manchester, on Monday, January 10th, 1898, at 7.30 p.m., when the following Amendments to Rules XXII. and XXXVI., agreed to at the special general meeting of the members held on the 22nd inst., will be submitted for adoption on the proposal of the Council:—

That Rule XXII. be altered to read as follows:—

The Council shall, previous to the annual general meeting in each year, prepare a list of members whom they propose as suitable for the offices of President, Hon. Treasurer, and Hon. Secretary for the ensuing year, and also a list of members who shall have been nominated for the four vacancies on the Council. Such nominations shall be effected by any retiring member of Council, or other qualified person, being proposed and seconded in writing by two members and supported by four other members. These nominations, together with the written consent of such nominees to accept office if elected, shall be forwarded to the secretary 21 days previous to the annual general meeting. If, after this date, there shall be no more nominations than vacancies the person so nominated become elected, but if there shall be more nominations than vacancies each member shall be at liberty to make a selection from such list, provided the number of names so selected shall not exceed in any case the number requisite to fill the vacancies. Ballot papers shall be so marked and recorded as may be from time to time determined by the Council.

That Rule XXXVI. be altered by the inclusion of the words shown in italics:—

Every Member or Associate shall have the privilege of introducing two visitors to the ordinary general meetings of the society, but no visitor *who is eligible as a Member or Associate* shall be permitted to attend more than twice in any one session except by permission of the Council.

Obituary.—We regret to announce the death, at Cadiz, on the morning of January 4th, of Mr. W. F. O'Brien. For some years past Mr. O'Brien had not enjoyed the best of health, but he had made, during his short stay at Cadiz, such marked improvement, that the news of the relapse which proved fatal, was received in London as an unexpected shock. A large number of our readers have met Mr. O'Brien either in business connected with telegraphic matters, or socially, and in his capacities, both as a telegraph man and as a friend, his loss will be deeply deplored by the large circle which appreciated his many sterling qualities. His knowledge of telegraph affairs, his grasp of every detail connected with his business, and his devotedness to the work, rendered him invaluable in the position he occupied; while his straightforward character and his constant readiness to attend to the interests of others secured for him many and sincere friendships. Mr. O'Brien, after serving in the Postal Telegraphs for some years, entered the employment of the Japanese Government at the moment when the development of the telegraph was first seriously commenced in Japan. On the termination of his agreement with the Japanese Government he joined, in 1875, the West Coast of America Telegraph Company. On the expiration of his term of service he returned to England, and was attached to the staff of the Silvertown Company, and lent valuable services on many cable expeditions. In 1884 he was appointed traffic accountant to the West African Telegraph Company, and at the time of his death held that position in the South American Cable Company and the Spanish National Submarine Telegraph Company. He served the latter company for fourteen years, and during the last year also acted as secretary. Mr. O'Brien attended, on behalf of the companies he served, the International Telegraph Conventions of Paris and Buda-Pesth. We beg to be permitted to offer his family our most sincere sympathies for the great loss they have sustained.

The Chatsworth Festivities.—Messrs. Drake & Gorham received instructions to carry out a number of illuminations in connection with the visit this week of the Prince and Princess of Wales to Chatsworth. The whole of the building was lit up by a special system of reflected light that was much admired. Jandus arc lamps were employed. A search light was fixed on a platform above the roof, and threw a beam on to each of two fountains. These fountains were each illuminated by means of four projectors worked from water-tight boxes placed in the centre of the fountain itself. An illuminating device, known as the electroflame, patented by the firm in connection with the Jubilee illuminations, was shown to great advantage in the centre of the building.

The Engineers' Strike.—Mr. Alexander Siemens, speaking at the dinner of the Article Club on Wednesday night, said the most important question for the commerce of England was at present the great struggle in the engineering trade. The struggle had been going on for six months, but the masters, whose interests were not much in common, had held together, and he could assure them that they would hold together still. There was not the slightest intention whatever on the part of the masters of going back from the terms they agreed upon at Westminster with regard to the management of works in the future, and they would not yield to the demand for diminished working hours. The masters had been defending the right of liberty. The trades unions would not allow their men to work as they could, and if any man was working particularly well, earning extra wages, and doing more than other men, he was hauled before the District Committee, and told he must restrict his production, or he would be fined, or expelled from the union. The masters wanted to do away with that kind of thing. At the same time they had made it compulsory that collective bargaining should be resorted to. With regard to these rules of management, he would call their attention to a very curious point. At the last sitting of the Conference the delegates of the men agreed to these rules, and said if they were given 54 hours' pay for 51 hours' work, they would accept the rules of management, and tell their men to go back to work on the following Monday. When, however, they found the masters would not give in on the question of hours, the delegates turned round and said the rules of management struck at the root of trades unionism, and they must refer the matter to the vote of the men. If the rules of management were right one moment, why were they wrong simply because the employers would not give way on the question of hours? Mr. Knight, the Secretary of the Boilermakers' Society, had also pointed out that his society had been working under these rules for years, and was flourishing under them, and they did not find them hostile to trades unionism. These rules, too, were not a new invention. They were only such as had been in use at some of the works of the Federated Employers where trade unionists were employed before the commencement of the dispute. Why, therefore, did the delegates say all of a sudden that they struck at the root of trades unionism? He would take that opportunity of saying that the Federated Employers had been resisting the demands of the trades unions quite as much in the interest of the individual workmen as in their own interest. The masters were absolutely united, as much now as they were on the first day during these six months, and, far from anybody having broken away from the Federation, other firms had joined and posted notices. That showed that they had a good cause, and they meant to fight for it to the end.

Congratulations.—In the list of New Year honours appears the name of Mr. Spencer Walpole, the secretary to the Post Office, who is made a K.C.B., also of Mr. James Dredge, whom the Queen, on the recommendation of the Secretary of State for Foreign Affairs, has appointed a C.M.G. in the Order of St. Michael and St. George. This honour is bestowed in recognition of services rendered in connection with the Brussels Exhibition. We have pleasure in congratulating Mr. Dredge.

Erratum.—In the article in last week's issue on "Localisation of Breaks and Partial Earth Faults in Submarine Cables," on p. 919 (December 31st, 1897) Formula B should read as follows:—$x = B_1 - (B_2 - B_1)$ ohms, *instead* of B_1 $(B_2 - B_1)$ ohms.

Fire.—During a cinematograph exhibition at Bolton last Saturday, a fire occurred in connection with the electrical apparatus. There was a panic among the audience, and the operator and others were slightly burned.

London Fogs and Artificial Light.—London fog absorbs 11·1 per cent. of the luminous rays from an ordinary gas flame, while 20·8 per cent. of the light from an incandescent mantle are lost in it. This is of course due to the fact that the first-mentioned light contains far more red rays than the other, and that fog permits the passage of red rays to the exclusion of the blue is evident from the deep red colour which the sun assumes when seen through mist.—Cosmos.

observations to the Board of Trade.—The Town Clerk read the following letter: "Local Government Board, Whitehall, S.W., December 23rd. Sir,—I am directed by the Local Government Board to advert to your letter of the 11th inst. relating to the application by the Town Council of Peterborough for sanction to borrow £15,000 for works of electric lighting, and I am to state that according to the latest information in the possession of the Board the Council's margin of borrowing powers is not sufficient to enable them to borrow the sum of £15,000 in addition to the sum of £4,500 for which they desire sanction to borrow for hospital purposes —I am, yours faithfully, A. D. Adrian, Assistant Secretary."—The matter came before a special Council meeting on Wednesday.

Power Distribution Scheme.—The Bill promoted by the General Power Distributing Company, for providing electric power in a 26 miles area was considered by the Council the other day, and it was resolved that the Bill be opposed, in conjunction with the other local authorities. The Nottingham City Council has appointed a strong committee to oppose the scheme.

Shoreditch.—The Lighting Committee has advised that the application of the County of London and Brush Electric Light Company for a way leave for cables in a direct line through, without supplying current in, the district of the Vestry, at a rent of £50 per annum, be not granted.

Swinton.—A Committee of the District Council is considering the question of electric lighting by a private company.

Torquay.—Under the direction of Mr. Storey, engineer-in-charge, the electric lighting works are being pushed forward. Two sets of machinery have been received, and all three boilers have been submitted to full steam pressure, the trials having proved in every way satisfactory. There are now 44 consumers on the mains, and 3,000 8-C.P. lamps have been placed in the residences and shops of the town. The streets will be lit by 57 arc lamps.

Tunbridge Wells.—It is proposed to accept the lowest tender sent in for building extensions to the electricity works, *i.e.*, that of Mr. W. J. Logan at £1,059.

Ventnor.—Mr. Pressland recently wrote on behalf of the Ventnor Electric Light and Power Company asking for the approval of the Council to the site for the station. The application was granted.

Walsall.—The Grand Theatre, Walsall, was lighted electrically on 22nd ult. for the first time. The stage is now illuminated by 170 electric lamps of various colours, which can be manipulated from a switchboard so arranged that the illumination can be red, green, or white at a moment's notice. The theatre itself is also now completely lighted with electricity.

Wednesbury.—The Council will oppose the application of the Midland Electric Corporation for a provisional order, it being considered that the work ought to be in its own hands.

West Hartlepool.—A Local Government Board inquiry was held last Tuesday *re* the Corporation's proposed £30,000 loan for electric lighting.

West Derby.—The Board of Guardians of the West Derby Union have instructed Mr. Thos. L. Miller, M.Inst E.E., of Liverpool, to prepare full plans and specifications, and to invite tenders, for the lighting of their Mill Road Infirmary by electricity. The installation, we understand, is estimated to cost upwards of £5,000.

Westminster.—The Board of the Westminster Electric Supply Corporation, Limited, has decided to reduce the rate of charge for electric energy as follows:—From January 1st, 1898, the price charged for current used for lighting purposes will be at the standard rate of 6d. per Board of Trade unit for the first 4,000 units used in each year. All units used in each year in excess of 4,000 will be charged at the net rate of 4d. per unit. The price charged for current used solely for purposes other than lighting, and supplied through a separate meter, will be at the rate of 3d. per Board of Trade unit.

Wormit.—Inquiries are being made among the residents as to whether they are in favour of electricity, gas, or oil as an illuminant for the village. If two-thirds are in favour of electric lighting a detailed scheme will then be submitted to a public meeting.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

Blackpool.—The Tramway Committee, a short time ago, applied to the Local Government Board for permission to substitute the overhead trolley system for the conduit system of electric traction on the promenade. Not only has the board refused this permission, but it has condemned the existing conduit system as well. This has come as a surprise upon the committee, who are going to interview the officials in London on the matter. Meanwhile they have decided to lay a tramline through Claremont Park, instead of along the low promenade.

Bristol.—Last Saturday the Tramway Committee appointed to negotiate with the Bristol Tramways and Carriage Company for the purchase of the system, reported to the City Council that the company absolutely refused to negotiate, and were now promoting two Bills for extending the system.

Collision.—On 26th ult. an electric tram collided violently with a motor car at Haddington Road, Dublin. The ends of both cars were considerably damaged. The cause of the accident is believed to be the failure of the motor brake to act.

Croydon.—A correspondent of the *Bullionist*, referring to the proposed purchase of the Croydon Tramways Company's undertaking by the British Electric Traction Company, says that the terms of the sale are "manifestly unfair to the ordinary shareholders." The meeting, he says, was held with doors closed to the press, and he is taking steps to see whether it is too late to prevent the sale on the terms proposed.

A Norwood paper says that the tramways system has been taken over by the British Electric Traction Company, who will introduce electrically-driven cars, and Mr. H. A. Durke's services are retained for the management of the new company.

Derby.—The proposed purchase of the tramways by the Council has been making progress in the hands of a committee, and the company has intimated that it is prepared to negotiate for the sale of the undertaking. With a view to making an offer to the company, the committee propose that an engineer be employed to advise them on the matter. The question of electricity is being taken into account.

Dublin.—The extension of the United Tramway system which will connect Rathmines by direct route with the electric tram near Ballsbridge is being pushed forward energetically. Already a large portion of the line is laid down. The length of the new tram line will be close on 2½ miles. The effect of the new line will be to connect the extremities of the southern townships from the eastern side of Rathmines Township at Haroldscross to the Pembroke Township at Ballsbridge, and thence near Haddington Road with Sandymount. The entire work is being carried out by the United Tramway Company's own men, who have laid the rails.

Light Railways.—The proposal of the British Electric Traction Company to construct light railways in the Fenton District is not to be opposed by the Fenton Council.

The proposals to construct light railways between Highgate and Finchley, and Finchley and Hendon, were before the Finchley District Council last week. Mr. Vesey Knox, M.P., barrister, appeared on behalf of the electric scheme, and submitted that the system proposed—overhead electric trolley—was the only one possible for such a rural district, and if there was a fatal objection to the system, that would be fatal to the scheme. They proposed to light the road along the line of route at a price to be agreed upon with the Council; a quick service to Hampstead, and, consequently, a service to the West-end of London and an additional local service to the Great Northern Railway. Owing to the provisions of the Tramways Acts, they proposed a street traction far superior to any existing in this country at present; fares of 1d. per mile (but anticipated four miles for 3d.); the average speed (time table), eight miles throughout, was proposed; repair of 18 inches on each side of the lines, which meant where double lines existed 16 feet; the posts would be of an ornamental character, on one side of the road only; purchase by the local authority at the end of 35 years. The only object they had in going under the Light Railways Act was to save the expense of a Parliamentary Bill. They intended putting on a special service for the working classes. They had power to carry goods, but the passenger traffic was looked to; they did not intend to combine goods and passenger cars.

Lucan Tramways.—The Lucan Steam Tram Company are, says *Freeman's Journal*, at present in communication with the Board of Trade with reference to the inspection of the line from the Conyngham Road to Leixlip. It is expected that the inspection will shortly be made, and that the line will soon afterwards be open for traffic. The line has been completely relaid, new rails put down, and the gauge has been widened from the former one of 3 feet to 3 feet 6 inches. The cost of re-sinking the line is nearly £16,000. The remaking was undertaken with a special view to the line being worked by electricity, and provision has been made for the ultimate carrying out of that intention. The introduction of electricity for traction purposes will involve an additional outlay of about £15,000. Until that work may be undertaken, the line will be worked by steam. It is estimated that the conversion of the line, as it is now constructed, into an electrically equipped line, will be carried out in four months, and that change will involve a stoppage of the traffic for that length of time. The board of directors are in negotiation with a London firm of contractors for this work, and if there is a prospect of the work being completed by the summer, it will be commenced as soon as the contract is signed. Otherwise the summer traffic will be carried on by the steam haulage, and the electrical equipment will be postponed until the close of the summer season. The trams with the steam haulage will run every hour, and with electric traction they will be run every half hour. The system of electric traction to be adopted is the trolley overhead wire. The power house will be erected about midway on the line, near St. Lawrence's Road. The dynamos will be driven entirely by steam, as the board has been advised that the water power would not be sufficient. When the contract is completed, the building of the power house will be first commenced.

Manchester.—The Special Committee of Tramways appointed by the Corporation recently resolved: "That the electrical equipment and the supply of the electric current necessary for the working of the tramways of the Corporation within the city be placed in the hands of the Electricity Committee, and that they be requested to take the necessary steps for the carrying out of the work; the terms of payment for the current to be supplied to be hereafter arranged." The Electricity Committee, with a view to carrying out this resolution,

The Northern Society of Electrical Engineers.—Notice is given that a special general meeting of the members of this society will be held at the Palatine Hotel, Manchester, on Monday, January 10th, 1898, at 7.30 p.m., when the following Amendments to Rules XXII. and XXXVI., agreed to at the special general meeting of the members held on the 22nd inst., will be submitted for adoption on the proposal of the Council:—

That Rule XXII. be altered to read as follows:—

The Council shall, previous to the annual general meeting in each year, prepare a list of members whom they propose as suitable for the offices of President, Hon. Treasurer, and Hon. Secretary for the ensuing year, and also a list of members who shall have been nominated for the four vacancies on the Council. Such nominations shall be effected by any retiring member of Council, or other qualified person, being proposed and seconded in writing by two members and supported by four other members. These nominations, together with the written consent of such nominees to accept office if elected, shall be forwarded to the secretary 21 days previous to the annual general meeting. If, after this date, there shall be no more nominations than vacancies the person so nominated become elected, but if there shall be more nominations than vacancies each member shall be at liberty to make a selection from such list, provided the number of names so selected shall not exceed in any case the number requisite to fill the vacancies. Ballot papers shall be so marked and recorded as may be from time to time determined by the Council.

That Rule XXXVI. be altered by the inclusion of the words shown in italics:—

Every Member or Associate shall have the privilege of introducing two visitors to the ordinary general meetings of the society, but no visitor *who is eligible as a Member or Associate* shall be permitted to attend more than twice in any one session except by permission of the Council.

Obituary.—We regret to announce the death, at Cadiz, on the morning of January 4th, of Mr. W. F. O'Brien. For some years past Mr. O'Brien had not enjoyed the best of health, but he had made, during his short stay at Cadiz, such marked improvement, that the news of the relapse which proved fatal, was received in London as an unexpected shock. A large number of our readers have met Mr. O'Brien either in business connected with telegraphic matters, or socially, and in his capacities, both as a telegraph man and as a friend, his loss will be deeply deplored by the large circle which appreciated his many sterling qualities. His knowledge of telegraph affairs, his grasp of every detail connected with his business, and his devotedness to the work, rendered him invaluable in the position he occupied; while his straightforward character and his constant readiness to attend to the interests of others secured for him many and sincere friendships. Mr. O'Brien, after serving in the Postal Telegraphs for some years, entered the employment of the Japanese Government at the moment when the development of the telegraph was first seriously commenced in Japan. On the termination of his agreement with the Japanese Government he joined, in 1875, the West Coast of America Telegraph Company. On the expiration of his term of service he returned to England, and was attached to the staff of the Silvertown Company, and lent valuable services on many cable expeditions. In 1884 he was appointed traffic accountant to the West African Telegraph Company, and at the time of his death held that position in the South American Cable Company and the Spanish National Submarine Telegraph Company. He served the latter company for fourteen years, and during the last year also acted as secretary. Mr. O'Brien attended, on behalf of the companies he served, the International Telegraph Conventions of Paris and Buda-Pesth. We beg to be permitted to offer his family our most sincere sympathies for the great loss they have sustained.

The Chatsworth Festivities.—Messrs. Drake & Gorham received instructions to carry out a number of illuminations in connection with the visit this week of the Prince and Princess of Wales to Chatsworth. The whole of the building was lit up by a special system of reflected light that was much admired. Jandus arc lamps were employed. A search light was fixed on a platform above the roof, and threw a beam on to each of two fountains. These fountains were each illuminated by means of four projectors worked from water-tight boxes placed in the centre of the fountain itself. An illuminating device, known as the electroflame, patented by the firm in connection with the Jubilee illuminations, was shown to great advantage in the centre of the building.

The Engineers' Strike.—Mr. Alexander Siemens, speaking at the dinner of the Article Club on Wednesday night, said the most important question for the commerce of England was at present the great struggle in the engineering trade. The struggle had been going on for six months, but the masters, whose interests were not much in common, had held together, and he could assure them that they would hold together still. There was not the slightest intention whatever on the part of the masters of going back from the terms they agreed upon at Westminster with regard to the management of works in the future, and they would not yield to the demand for diminished working hours. The masters had been defending the right of liberty. The trades unions would not allow their men to work as they could, and if any man was working particularly well, earning extra wages, and doing more than other men, he was hauled before the District Committee, and told he must restrict his production, or he would be fined, or expelled from the union. The masters wanted to do away with that kind of thing. At the same time they had made it compulsory that collective bargaining should be resorted to. With regard to these rules of management, he would call their attention to a very curious point. At the last sitting of the Conference the delegates of the men agreed to these rules, and said if they were given 54 hours' pay for 51 hours' work, they would accept the rules of management, and tell their men to go back to work on the following Monday. When, however, they found the masters would not give in on the question of hours, the delegates turned round and said the rules of management struck at the root of trades unionism, and they must refer the matter to the vote of the men. If the rules of management were right one moment, why were they wrong simply because the employers would not give way on the question of hours? Mr. Knight, the Secretary of the Boilermakers' Society, had also pointed out that his society had been working under these rules for years, and was flourishing under them, and they did not find them hostile to trades unionism. These rules, too, were not a new invention. They were only such as had been in use at some of the works of the Federated Employers where trade unionists were employed before the commencement of the dispute. Why, therefore, did the delegates say all of a sudden that they struck at the root of trades unionism? He would take that opportunity of saying that the Federated Employers had been resisting the demands of the trades unions quite as much in the interest of the individual workman as in their own interest. The masters were absolutely united, as much now as they were on the first day during these six months, and, far from anybody having broken away from the Federation, other firms had joined and posted notices. That showed that they had a good cause, and they meant to fight for it to the end.

Congratulations.—In the list of New Year honours appears the name of Mr. Spencer Walpole, the secretary to the Post Office, who is made a K.C.B., also of Mr. James Dredge, whom the Queen, on the recommendation of the Secretary of State for Foreign Affairs, has appointed a C.M.G. in the Order of St. Michael and St. George. This honour is bestowed in recognition of services rendered in connection with the Brussels Exhibition. We have pleasure in congratulating Mr. Dredge.

Erratum.—In the article in last week's issue on "Localisation of Breaks and Partial Earth Faults in Submarine Cables," on p. 919 (December 31st, 1897) Formula B should read as follows:—$x = R_1 - (R_2 - R_1)$ ohms, *instead* of $R_1 (R_2 - R_1)$ ohms.

Fire.—During a cinematograph exhibition at Bolton last Saturday, a fire occurred in connection with the electrical apparatus. There was a panic among the audience, and the operator and others were slightly burned.

London Fogs and Artificial Light.—London fog absorbs 11·1 per cent. of the luminous rays from an ordinary gas flame, while 20·8 per cent. of the light from an incandescent mantle are lost in it. This is of course due to the fact that the first-mentioned light contains far more red rays than the other, and that fog permits the passage of red rays to the exclusion of the blue is evident from the deep red colour which the sun assumes when seen through mist.—COSMOS.

Electric Launch for the Czar of Russia.—At the time of the great Naval Parade in New York Harbour, in 1892, the Grand Duke Alexander, in command of the Russian warships, was so pleased with the electric launch of the U.S. cruiser *New York*, that he purchased it from the Navy Department for his own use. The performance of this boat, built by the Electric Launch Company, of New York, came under the notice of the Czar of Russia, and the result has been, says the New York *Electrical Engineer*, that the latter, a short time ago, ordered one for his own use, which is now under construction at the works of the Electric Launch Company, at Morris Dock, N.Y., under the personal supervision of Mr. J. C. Chamberlain, president of the company, in connection with Capt. D. T. Mertvago, naval attaché of the Russian Legation at Washington. The dimensions of the gig will be as follows:—Length over all, 37 feet; length on load water line, 35 feet; beam, extreme outside of planking, 7 feet 3¾ inches; draught of hull, 2 feet 8 inches; length of cockpit, or seating space, 14 feet 9 inches; greatest width of same, 6 feet 5 inches; displacement, without passengers, not to exceed 5·2 tons. The storage batteries, furnished by the Electric Storage Battery Company, will be of the most improved and modern type, all contained in hard rubber cells, with tight-fitting covers, and placed under the flooring and seats. The number and grouping will be such as to adapt them to be charged from a 110-volt circuit. The motor built to conform to the hull will be of special marine type with self-contained ball-bearing thrust fitted under the floor in its compartment, and directly connected with the propeller shaft. The controller for regulating the speed of the motor will be placed under the forward deck, and operated by a shaft extending through the steering wheel bearing. This controller will be capable of effecting five variable speed rates, from slow starting to spurting speed, and also adapted for reversing the motor with three variable speeds. The gig is to have a speed of eight miles an hour for three hours, or seven miles an hour for six hours, but the controller is arranged to admit of a spurting speed up to 11 miles per hour if desired. The gig is to be delivered and placed in commission by the builders' representative, who is also to instruct the crew in its care and operation.

Motor Cars.—A letter, evidently "writ sarcastic," appears in the *Engineer* from one "J. G. S.," who wants a motor carriage of some kind. He can find no advertisers of these vehicles, and asks are makers full of orders, and overflowing? We think not. There are, we believe, some genuine makers of motor carriages, but we fancy that many of the much-puffed companies which were started to make motor cars were left by their philanthropic promoters with insufficient capital to properly carry on the manufacture and the exploitation of the new industry. But all were not imaginary, and from time to time vehicles appear in the streets of London which seem to evidence the fact that there is a motor car industry.

NEW COMPANIES REGISTERED.

Wm. Coates & Son, Limited (2,172).—Registered in Dublin December 22nd, with capital £25,000 in £10 shares, to carry on a or any of the following businesses, either wholesale or retail, and either jointly or solely with others, electrical engineering in all its branches, plumbers, gas or steam fitters, &c. The subscribers (with one share each) are:—W. T. Coates, 1—11, Fountain Street, Belfast, merchant; W. C. Macann, 1—11, Fountain Street, Belfast, merchant; E. S. Dashwood, 1—11, Fountain Street, Belfast, electrical engineer; G. D. Coates, 5, Chilworth, Belfast, bank manager; R. Hamilton, 37, University Road, Belfast, secretary; T. G. Megaw, 1—11, Fountain Street, Belfast, cashier; T. J. Moore, 1—11, Fountain Street, Belfast, salesman. The number of directors is not to be less than three nor more than five. The first are W. T. Coates, W. C. Macann, and E. S. Dashwood; qualification, 200 shares; remuneration as fixed by the company. Registered by Crawford & Lockha, 8, Anglesea Street.

City of Mexico Electric Power Syndicate, Limited (55,438).—Registered December 30th, with capital £5,000 in £50 shares (40 preference), to acquire any rights and grants for producing electricity for lighting, motive, and other purposes in Mexico or elsewhere, and to carry on the business of electrical engineers and contractors. The subscribers (with one share each) are:—H. K. Baynes, 15, Chapel Street, Belgrave Square, S.W., solicitor; F. S. Courtney, C.E., 39, Alleyn Park, Dulwich; J. T. Toomer, C.E., Queen Anne's Mansions, Westminster; T. P. Wilson, C.E., Holmhurst, Belvedere, Kent; A. P. Friend, Ouseley House, Erith, Kent, engineer; R. J. Price, M.P., 104, Sloane Street, S.W.; C. F. Sillem, Broad Sanctuary Chambers, Westminster, engineer. The number of directors is not to be less than three, nor more than five. The first are J. Price, H. K. Baynes, and J. F. Toomer. Registered by Goldring & Hargrove, 99, Cannon Street, E.C.

CITY NOTES.

Kelvinside Electricity Company.

The annual meeting of this company was held at 28, Renfield Street, Glasgow, on the 29th inst., Mr. J. B. Fleming presiding.

The Chairman, in moving the adoption of the report, said they had not to report a very flourishing concern. They had no dividend to give, but it was perfectly obvious they had turned the corner, and were not far away from success. Several elements had led to that. Mr. Sharpe had induced a good many people to become users of the light, and he believed that his work would become more apparent in the future. The number of consumers was gradually and steadily increasing, but these were not coming in so rapidly as he could wish.

Mr. Reckett seconded the motion.

In answer to questions, the Chairman said they could supply three times the amount of light they were doing at present. The people of Partick were anxious to get the light, and, in addition to householders on the top of the hill, many shopkeepers were desirous of having it. If they had the light in Partick, he was convinced that the company would be a paying concern. He thought they were likely to get the provisional order for Partick, as he did not think the opposition of Glasgow would count for much. He further stated that the revenue this year had been £1,573 11s. 6d., an increase of £151 17s. 8d. over the previous year. The number of units used was 63,562, as compared with 63,467 last year. Although that was only an increase of 95, there was this fact that it included a larger number of private houses, for the cyanide works, which had used a considerable quantity of light in 1895, and rather less last year, would be off this year. The number of units of light sold to private houses was 52,586, against 35,545 in the previous year, showing an increase in that department of nearly 50 per cent

The report was adopted.

Messrs. J. B. Fleming and Reckett were re-elected directors.

Babcock & Wilcox, Limited.

At an extraordinary general meeting of this company, held on 29th ult., at the Cannon Street Hotel, Sir W. Arrol, M.P., presiding, the resolutions passed on the 14th inst., for increasing the capital of the company to £320,000 by creating 8,000 new ordinary shares of £10 each, to rank *pari passu* with the existing ordinary shares, and to rank for dividend as from the 1st inst., were confirmed as special resolutions, on the motion of the chairman, seconded by Mr. M. Rumley. The chairman, in answer to a question, stated that notices to the shareholders would go out in a day or two, and every preference and ordinary shareholder would be entitled to his fair proportion of the new shares.

London Electric Supply Corporation.—According to the *Daily Mail*, when the accounts of this company are made up for 1897 it is proposed to take the concern out of the receiver's hands, to reconstruct the company, and to reduce the capital by writing off £2 or £3 from the ordinary shares. This would place the corporation on a sound basis. The company is doing a big business, and rapid strides are being made. The dividend on the preferences was earned last year, while there was also a small amount left for the ordinary, so that in future preference holders may expect to receive their 6 per cent. in full.

The City of London Electric Lighting Company, Limited.—Warrants for interest due on 31st ult. on the £400,000 5 per cent. debenture stock have been duly posted.

Electric Construction Company.—The transfer books for the first mortgage debentures will be closed from 8th to 14th inst inclusive.

TRAFFIC RECEIPTS.

The City and South London Railway Company. The receipts for the week ending January 2nd. 1898, were £1,050; week ending January 3rd, 1897, £1,077; decrease, £27; total receipts for half-year, 1898, £1,050; corresponding period, 1897, £1,077; decrease, £27.

The Liverpool Overhead Railway Company. The receipts for the week ending January 2nd, 1898, amounted to £1,357; corresponding week last year, £1,374; decrease, £17.

The Western and Brazilian Telegraph Company, Limited. The receipts for the week ending December 31st, 1897, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £2,384.

THE APPLICATION OF VECTOR ALGEBRA TO ALTERNATING CURRENTS.

By W. G. RHODES, M.Sc., Royal Technical Institute, Salford.

INTRODUCTION.

1. Any physical quantity which requires for its complete specification data regarding (1) its *magnitude*, (2) its *direction*, and (3) its *sense* along that direction, is called a vector quantity. Quantities which are completely specified when their magnitudes only are given are called *scalar* quantities.

Mass and power are examples of scalar quantites: velocity, accleration, force, electric currents, and electromotive forces are examples of vector quantities.

A vector quantity may be completely represented by a straight line drawn in a particular direction, the sense along the direction being shown by means of an arrow head, and the line containing as many units of length as the quantity to be represented contains units of quantity.

We shall call a line drawn in this way *a vector*, *e.g.*, the vector, O P (fig. 1), may represent an electric current if its direction is represented

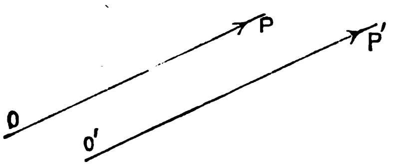

Fig. 1.

by the line O P, its sense from O to P along this direction, and if O P contains as many units of length as the number of amperes in the electric current.

Two vectors are equal if they contain the same number of units of length, are parallel to the same direction, and have the same sense: thus in fig. 1 the vector O P, is equal to the vector $O^1 P^1$, if the length of O P equals that of $O^1 P^1$. The vector P O, we may note, is minus the vector O P.

2. *Composition of Vectors.*—The sum of two vectors, O P and P Q

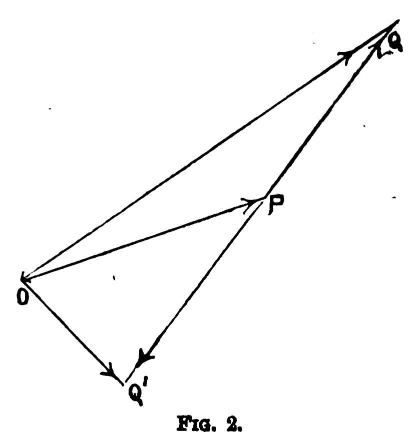

Fig. 2.

(fig. 2), is defined to be the vector O Q. The meaning of the word *sum* is here extended, and if we write

$$OP + PQ = OQ,$$

we should read O P together with P Q are equivalent to O Q. The addition of vectors is thus the same as the addition of forces, for if O P and P Q represent two forces, then O Q represents their resultant. The difference of two vectors, O P and P Q, is defined to be the sum of the two vectors, O P and Q P, and is, therefore, the vector $O Q^1$ (fig. 2), where $P Q^1 = - P Q$.

3. *Algebraic Representation of a Vector Quantity.*—Let O P (fig. 3) represent any vector quantity.

Through O draw any two mutually perpendicular lines, $x\,O\,x^1$, $y\,O\,y^1$. Draw P N perpendicular to $x\,O\,x^1$: the two vectors, O N and N P, are then together equal to the vector, O P. Any vector can thus be resolved into two component vectors parallel respectively to $x\,O\,x^1$

and y O y^1. Now let us agree to represent unit vector along O x by $+1$; unit vector along O x^1 will then be represented by -1, since the sense is exactly opposite. Let us further represent unit vector along O y by k; then unit vector along O y^1 will be represented by $-k$. If, then, O N contains a units of length, and N P contains b units, the vector, O P, is represented by $a + k\,b$ and its magnitude is $\sqrt{a^2 + b^2}$: also its inclination to O x is given by $\tan\theta = \frac{b}{a}$. In the same way $-a + k\,b$ represents a vector lying in the quadrant, y O x^1; $-a - k\,b$, one lying in the quadrant, x^1 O y^1; and $a - k\,b$, one lying in the quadrant, y^1 O x.

If P Q (fig. 3) is another vector whose components parallel to O x

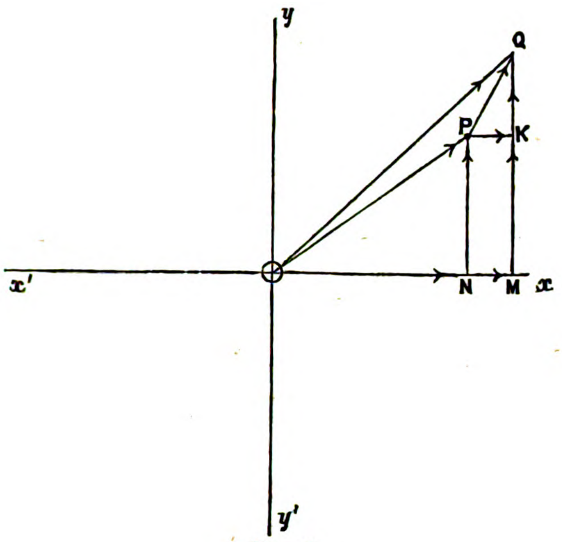

Fig. 3.

and O y are respectively P K = N M = a' and K Q = $b'\,k$, then the vector, P Q, is represented by $a^1 + k\,b^1$, and the vector, O Q, which is the sum of the vectors, O P and P Q, is given by

$$\begin{aligned} \text{OQ} &= \text{OM} + \text{MQ} \\ &= (\text{ON} + \text{NM}) + (\text{MK} + \text{KQ}) \\ &= (a + a') + (k\,b + k\,b') \\ &= (a + a') + k\,(b + b') \end{aligned}$$

This gives the law of vector addition, and inherently contains that of subtraction also, the difference of the vectors, O P and P Q being represented by

$$(a - a') + k\,(b - b').$$

4. *Product of two vectors.*—Consider any two vectors, O P and O Q (fig. 4), and let O P = O N + N P, where N P is at right angles to O Q.

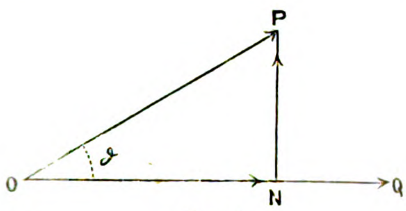

Fig. 4.

There are two products to take into consideration, viz., the product O Q . O N and the product O Q . N P.

To interpret these, suppose that the vector O P represents a displacement, and the vector O Q a force. The product O Q . O N then represents the *work* done by the force in moving its point of application from O to N. This product is essentially scalar.

The product, O Q . N P, represents the *moment* of the force about the point, P, and is a *vector at right angles to the plane*, O P N. We shall not, however, consider this vector product further in the present paper; it is the scalar product, O Q . O N, with which we are at present concerned. By reference to fig. 4, we see that

$$\text{OQ} \,.\, \text{ON} = \text{OQ} \,.\, \text{OP} \cos\theta,$$

so that the scalar product of two vectors is the product of their lengths multiplied by the cosine of the angle between their directions.

5. Let the vector O P be represented algebraically by $a + k\,b$, and the vector O Q by $a' + k\,b'$: then (see fig. 5 and Section 3) the magnitude of O P is $\sqrt{a^2 + b^2}$, that of O Q is $\sqrt{a'^2 + b'^2}$, and the angle, θ, between their directions is

$$\theta = \theta_1 - \theta_2$$

where

$$\tan\theta_1 = \frac{b}{a} \text{ and } \tan\theta_2 = \frac{b'}{a'},$$

therefore,

$$\cos\theta = \cos(\theta_1 - \theta_2) = \cos\theta_1\cos\theta_2 + \sin\theta_1\sin\theta_2.$$

$$= \frac{a}{\sqrt{a^2 + b^2}} \cdot \frac{a'}{\sqrt{a'^2 + b'^2}} + \frac{b}{\sqrt{a^2 + b^2}} \cdot \frac{b'}{\sqrt{a'^2 + b'^2}}$$

that is

$$\sqrt{a^2 + b^2}\,\sqrt{a'^2 + b'^2}\cos\theta = a\,a' + b\,b'.$$

Thus the scalar product of the two vectors $a + k\,b$ and $a' + k\,b'$ is $a\,a' + b\,b'$.

6. *On k as an Operator.*—A vector whose length is a along or parallel to O x is represented by a, whereas a vector of the same length whose direction is parallel to O y is represented by $k\,a$. We

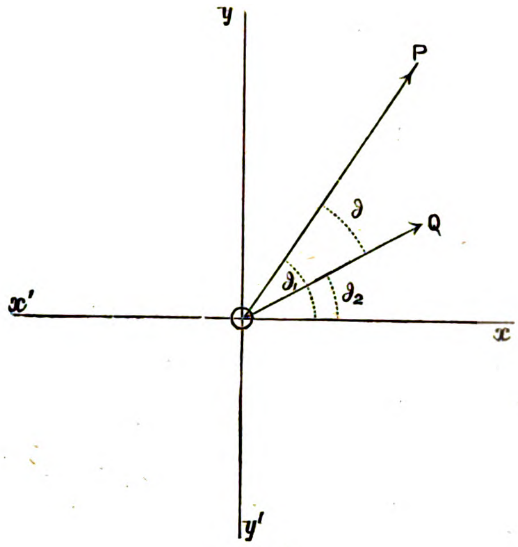

Fig. 5.

may thus regard k as an operator which has the effect of turning a vector along O x, through a right-angle in the positive (counter-clockwise) direction of rotation without altering its length. The effect of similarly operating on $k\,a$ must, therefore, to be consistent, be to turn the vector, $k\,a$, through a right-angle in the positive direction of rotation without altering its length; that is, it becomes a vector of length, a, along O x^1, that is, it becomes $-a$. We thus have

$$k \,.\, k\,a = k^2\,a = -a$$

or

$$k^2 = -1,$$

that is, when using the symbol k in algebraical processes, we must regard it as having the properties of the imaginary $\sqrt{-1}$. If we similarly operate on the vector $-a$, we get $-k\,a$, a vector of length along O y^1, and operating again we get $-k^2\,a$ or $+a$, a vector of length a along O x.

7. Again operating on any vector $a + k\,b$, we get $k\,(a + k\,b)$ or $k\,a - b$, which is the vector $a + k\,b$ turned through a right angle in the positive direction. That is, if O P is any vector, then k . O P is the vector resulting from a rotation of the vector O P through a right angle in the positive direction of rotation. By similar reasoning we can show that $-k$. O P represents the vector resulting from a rotation of the vector O P through a right angle in the negative (clockwise) direction of rotation.

8. *Definition.*—A vector O P is said to lead before, or lag behind, a vector O Q, according as the least amount of rotation necessary to bring O P into the same direction as O Q is in the negative or positive direction.

It is easily seen, then, that the vector, k . O P, leads before the vector, O P, by a right angle, while the vector $-k$. O P lags behind the vector O P by a right angle.

Application to Alternating Currents.

9. Before proceeding to apply the foregoing principles to alternating current calculations, we must first establish three important propositions.

Proposition 1.—The maximum value of the induced electromotive force, due to self-induction in a circuit, is $p\,\text{L}\,i$, where i is the maximum value of the current in the circuit, L is the self-induction of the circuit, and $p = 2\,\pi\,n$, where n is the frequency of the current. Also the E.M.F. of self-induction *lags a right angle behind the current.*

Let the current be $i \sin p\,t$, then the E.M.F. of self-induction is given by

$$\begin{aligned} e &= -\text{L}\frac{d}{d\,t} \,.\, i \sin p\,t \\ &= -p\,\text{L}\,i\cos p\,t \\ &= p\,\text{L}\,i \sin\left(p\,t - \frac{\pi}{2}\right) \end{aligned}$$

which proves the proposition.

Proposition 2.—If two circuits, A and B, have a mutual induction M, the maxima values of the consequent E.M.Fs. in the circuits A and B are respectively $p\,\text{M}\,i_2$ and $p\,\text{M}\,i_1$, where i_1 is the maximum value of the current in the circuit A, and i_2 that in the circuit B, and these induced E.M.Fs. lag a right angle behind the currents i_2 and i_1 respectively.

Let the current in the circuit, B, be $i_2 \sin p\, t$, then the E.M.F. in the circuit due to mutual induction is given by

$$e = -\,M \frac{d}{d\,t} \cdot i_2 \sin p\, t$$
$$= -\,p\,M\, i_2 \cos p\, t$$
$$= p\,M\, i_2 \sin \left(p\, t - \frac{\pi}{2}\right).$$

Similarly for the E.M.F. of mutual induction in the circuit, A. Thus the proposition is established.

Proposition 3.—If a condenser of capacity C is placed in an alternating current circuit, there is a consequent E.M.F. whose maximum value is $\frac{i}{p\,C}$, where i is the maximum value of the current flowing through the circuit, and this capacity E.M.F. *leads before the current* by a right angle.

Let q be the charge on the condenser at any instant when the current is $i \sin p\, t$, then the potential difference at its terminals at that instant is $-\frac{q}{C}$, but we have

$$q = \int i \sin p\, t\, d\, t = -\frac{i}{p} \cos p\, t.$$

Therefore, the capacity E.M.F. is given by

$$e = -\frac{q}{C}$$
$$= \frac{i}{p\,C} \cos p\, t$$
$$= \frac{i}{p\,C} \sin \left(p\, t + \frac{\pi}{2}\right),$$

which shows that e leads a right angle before i, and that its maximum value is $\frac{i}{p\,C}$. The foregoing three propositions will be in constant demand in the sequel so that they should be thoroughly understood.

10. The method of represent alternating currents and E.M.Fs. by by means of so-called clock diagrams has been so fully dealt with by Dr. Fleming, Mr. Kapp, and other writers on the subject, as to render further explanation of the method here unnecessary; suffice it to say, that if the vector, O P (see fig. 3), is drawn of such a length as to represent in magnitude the *maximum* value of an alternating current or electromotive force, and if it is caused to rotate about O with a uniform angular velocity, p, in the positive direction of rotation, then the vectors, O N and N P, will represent the instantaneous values according as the current or E.M.F. is zero, and increasing *positively* when O P coincides in direction with O y^1 or O x.

Circuits Containing Resistance and Self-Induction Only.

11. Now let O P = i be a vector representing the maximum current in any circuit containing self-induction, then by Proposition (1) and Section 8, the vector representing the maximum value of the E.M.F. of self-induction in the circuit in which the current, i, is flowing is $-\,k\,p\,L\,i$, where L is the self-induction and $p = 2\,\pi\,n$, n being the frequency of the current. If the current is caused by a potential difference whose maximum value is represented by a vector, e, then the vector, e, has to supply a component, $r\,i$, in the direction of the

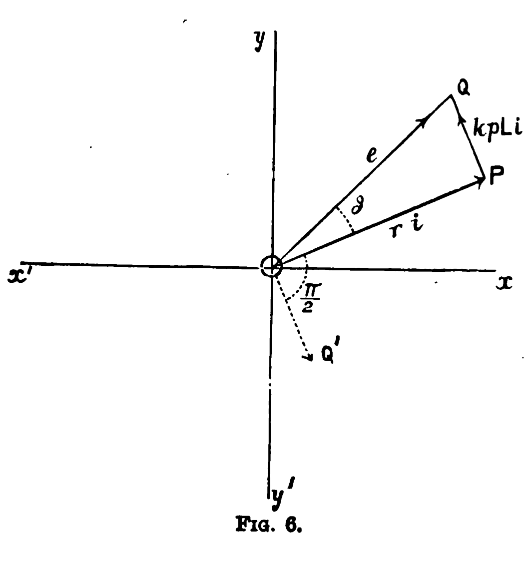

Fig. 6.

vector, i, to drive the current against the ohmic resistance r of the circuit, and also a component $+\,k\,p\,L\,i$ to balance the E.M.F. $-\,k\,p\,L\,i$ of self-induction. We thus have the vector equation

$$r\,i + k\,p\,L\,i = e, \qquad (1)$$

which is essentially a vector equation of E.M.Fs.

If we reduce the lengths of each of these vectors in the ratio, $1 : \sqrt{2}$, we may regard the vectors as representing root mean square values, but this alteration would not produce any change in equation (1), which only depends upon ratios of magnitudes of vectors.

If then a potential difference, e, of frequency, n, is applied between the terminals of an inductive circuit of resistance, r, and self-induction, L, then the vector equation (1) holds good, p being equal to $2\,\pi\,n$.

Let O P (fig. 6) represent the vector $r\,i$, then the vector O $Q^1 = -\,k\,p\,L\,i$ represents the E M.F. of self-induction, and the vector P Q $= +\,k\,p\,L\,i$ is the vector representing the E.M.F. necessary to overcome self-induction: therefore, the vector O Q = O P + P Q is the vector representing the applied potential difference e. Further, the vector O P, which is in phase with the current, lags behind the vector representing e by an angle θ, where

$$\tan\,\theta = \frac{p\,L}{r}.$$

Also (see Section 3) the *magnitude* of e is given by

$$e = \sqrt{r^2\,i^2 + p^2\,L^2\,i_2}$$
$$= i\,\sqrt{r^2 + p^2\,L^2}$$

that is
$$i = \frac{e}{\sqrt{r^2 + p^2\,L^2}} \qquad (2)$$

Equation (2), it must be noticed, is not the same as equation (1); it is one of several deductions from equation (1). Whereas (1) is a *vector* equation, involving directions as well as magnitudes; (2) involves magnitudes only.

The quantity $\sqrt{r^2 + p^2\,L^2}$ is called the impedance of the circuit.

12. Referring again to equation (1), it may be written

$$i\,(r + k\,p\,L) = e$$

or
$$i = \frac{e}{r + k\,p\,L}$$
$$= \frac{e\,(r - k\,p\,L)}{(r + k\,p\,L)\,(r - k\,p\,L)}$$
$$= \frac{e\,(r - k\,p\,L)}{r^2 + p^2\,L^2}$$
$$= \frac{r}{r^2 + p^2\,L^2}\,e - \frac{p\,L}{r^2 + p^2\,L^2} \cdot k\,e, \qquad (3)$$

which is a current vector equation, and states that the current, i, can be resolved into a component $\frac{r}{r^2 + p^2\,L^2} \cdot e$ parallel to the direction of e, and a lagging component $\frac{p\,L}{r^2 + p^2\,L^2}\,(-\,k\,e)$ at right-angles to the direction of e. This is shown graphically in fig. 7, where O P is the

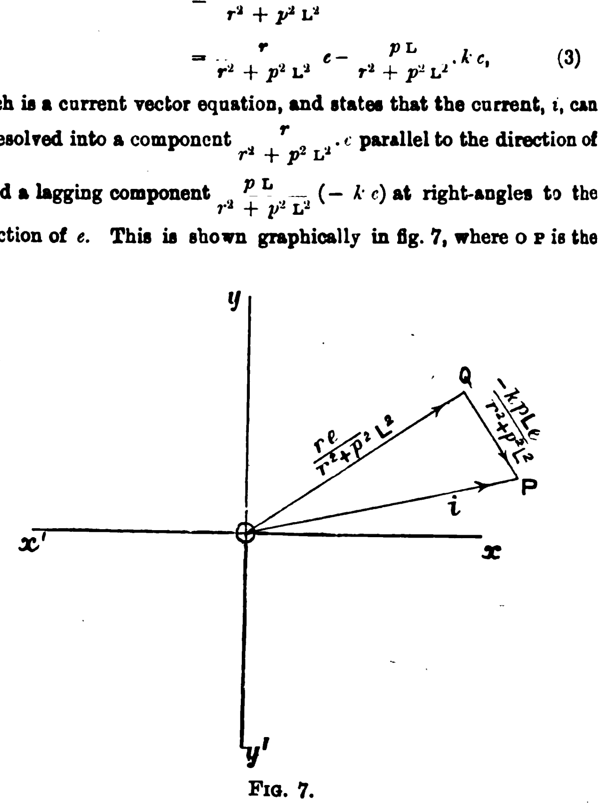

Fig. 7.

current vector, and O Q and Q P its components respectively along and at right angles to the direction of e. It should be noticed that the product $(r + k\,p\,L)\,(r - k\,p\,L)$, which equals $r^2 + p^2\,L^2$, since $k^2 = -\,1$, is not a vector product: the quantities, r, p, and L, are all scalar and have no right whatever to be treated as vectors after the manner of some writers on the subject.

We shall frequently make use of the vector equations (1) and (3) so they should be thoroughly understood. In fact, to proceed further without first mastering them would be useless.

13. Suppose now that any number, n, of inductive circuits are connected in series and it is required to find their equivalent resistance, self-induction, and impedance,

Let $r_1, r_2, r_3 \ldots . r_n$ be the ohmic resistances of the several circuits.

" $L_1, L_2, L_3 \ldots . L_n$ their self-inductions.

" $e_1, e_2, e_3 \ldots . e_n$ the vectors representing the potential differences between their respective terminals.

" i the vector representing the current flowing through the series circuit.

" $p = 2\,\pi\,n$, where n is the frequency of the current.

Then, the vector representing the potential difference between the extreme terminals of the series circuit is given by the *vector* equation

$$e = e_1 + e_2 + e_3 + \ldots . + e_n.$$

But by equation (1)

$$e_1 = r_1 i + k p L_1 i$$
$$e_2 = r_2 i + k p L_2 i$$
$$e_3 = r_3 i + k p L_3 i$$
$$\cdots\cdots$$
$$e_n = r_n i + k p L_n i.$$

Now all the $r i$'s are in the same direction, viz., along the current vector, as also are all the $k p L i$'s, viz., leading a right angle in front of the current vector; they can, therefore, be added together numerically, and we get

$$e = e_1 + e_2 + e_3 + \ldots + e_n$$
$$= (r_1 + r_2 + r_3 + \ldots + r_n) i + k p (L_1 + L_2 + L_3 + \ldots + L_n) i \qquad (4)$$

But if R and L are the equivalent resistances and self-inductions of the complete circuit, we have by equation (1)

$$e = R i + k p L i \qquad (5)$$

Comparing equations (4) and (5) we see that

$$R = r_1 + r_2 + r_3 + \ldots + r_n$$

and

$$L = L_1 + L_2 + L_3 + \ldots + L_n$$

and the impedance, I, is given by

$$I = \sqrt{R^2 + p^2 L^2}.$$

(*To be continued.*)

ELECTRIC LIGHTING PROVISIONAL ORDERS.—SESSION 1898.

LIST of applications for provisional orders deposited with the Board of Trade, on or before December 21st, 1897, under the provisions of the Electric Lighting Acts, 1882 to 1890.

Title of order and description of area.	Name of promoters.	Agents.
Airdrie Burgh Electric Lighting Order. The Burgh of Airdrie.	The Corporation.	Messrs. Martin and Leslie, 27, Abingdon Street, Westminster, S.W.
Aldershot Electric Lighting Order. The Urban District of Aldershot.	The Urban District Council.	Messrs. Blyth, Dutton, Hartley and Blyth, 112, Gresham House, Old Broad Street, E.C.
Aston Manor Electric Lighting Order. The Urban District of Aston Manor.	The Urban District Council.	Messrs. Sharpe & Co., 9, Bridge Street, Westminster, S.W.
Barnes Electric Lighting Order. The Urban District of Barnes.	The Urban District Council.	T. Blanco White, Esq, 59 and 60, Chancery Lane, W.C.
Batley Electric Lighting Order. The Borough of Batley.	The Corporation.	Messrs. Dyson & Co., 9, Great George Street, Westminster, S.W.
Birkdale Electric Lighting Order. The Urban District of Birkdale.	The Urban District Council.	Messrs. Sharpe & Co., 9, Bridge Street, Westminster, S.W.
Bolton Electric Lighting Order. The County and Municipal Borough of Bolton, the Urban District and Township of Astley Bridge, and the Townships of Heaton, Smithills, Darcy Lever, Breightmet, Lostock, Deane - over - Hulton, Middle Hulton, Tonge, and Great Lever, within the Bolton Rural District.	The Corporation of Bolton.	Messrs. Dyson & Co., 9, Great George Street, Westminster, S.W.
Brechin Electric Lighting Order. The Royal Burgh of Brechin.	The Corporation.	Messrs. Clarkson and Toovey, 98, Great Tower Street, E.C.
Bridgwater Corporation Electric Lighting Order. The Borough of Bridgwater.	The Corporation.	Messrs. Torr & Co., 19, Abingdon Street, Westminster, S.W.
Burslem Electric Lighting Order. The Borough of Burslem.	The Corporation.	Messrs. Sharpe & Co., 9, Bridge Street, Westminster, S.W.
Chelmsford Rural District Electric Lighting Order. The Parishes of Writtle, Great Baddow, Broomfield, Springfield and Widford, within the Chelmsford Rural District.	Chelmsford Electric Lighting Company, Ltd.	Messrs. Deacon and Co., 9, Great St. Helen's, E.C.
Chichester Corporation Electric Lighting Order. The City of Chichester.	The Corporation.	Messrs. Baker & Co., 22, Great George Street, Westminster, S.W.
Chislehurst Electric Lighting Order. Portion of the Parish of Chislehurst.	Chislehurst Electric Supply Company, Limited.	Messrs. Baker, Blaker & Hawes, 117, Cannon Street, E.C.
Chorley Corporation Electric Lighting Order. The Borough of Chorley.	The Corporation.	Messrs. Lewin, Gregory & Anderson, 13, King Street, Whitehall, S.W.
Colne Corporation Electric Lighting Order. The Municipal Borough of Colne.	The Corporation.	Messrs. Baker & Co., 22, Great George Street, Westminster, S.W.
Crewe Electric Lighting Order. The Borough of Crewe.	The Corporation.	Messrs. Sharpe & Co., 9, Bridge Street, Westminster, S.W.
Darlington Electric Lighting Order. The whole of the Borough of Darlington, except the detached portion of the Township or Civil Parish of Darlington known as Oxen-le-Field.	The Corporation.	Messrs. Durnford and Co., 38, Parliament Street, Westminster, S.W.
Dartford Electric Lighting Order. The Urban District of Dartford.	The Urban District Council.	Messrs. Baker & Co., 22, Great George Street, Westminster, S.W.
Doncaster Corporation Electric Lighting Order. The Borough of Doncaster.	The Corporation.	Messrs. Sherwood and Co., 7, Great George Street, Westminster, S.W.
East Ham Electric Lighting Order. The Urban District of East Ham.	The Urban District Council.	Messrs. Baker & Co., 22, Great George Street, Westminster, S.W.
East Stonehouse Electric Lighting Order. The Urban District of East Stonehouse.	The Urban District Council.	Do.
Gravesend Electric Lighting Order. The Municipal Borough of Gravesend.	The Corporation.	Messrs. Deacon and Co., 9, Great St. Helen's, E.C.
Greenock, Port-Glasgow, and Gourock Electric Lighting Order. The Burghs of Greenock, Port-Glasgow, and Gourock.	North British Electricity Supply Company, Ltd.	Messrs. Sherwood and Co., 7, Great George Street, Westminster, S.W.
Hamilton Electric Lighting Order. The Burgh of Hamilton.	The Corporation.	Messrs. Grahames, Currey & Spens, 30, Great George Street, Westminster, S.W.
Hastings Corporation Electric Lighting Order. The Borough of Hastings	The Corporation.	Messrs. Bircham and Co., 46, Parliament Street, Westminster, S.W.
Hereford Electric Lighting Order. The City of Hereford.	The Corporation.	Messrs. Andrews and Fawcus, 18, Essex Street, Strand, W.C.
Hornsey Electric Lighting Order. The Urban District of Hornsey.	The Urban District Council	Leonard J. Tatham, Esq., 17, Bedford Row, W.C.
Hove (Aldrington) Electric Lighting Order. The Parish of Aldrington in the town of Hove.	The Hove Urban District Council.	Messrs. Bircham and Co., 46, Parliament Street, Westminster, S.W.
Ilford Electric Lighting Order. The Urban District of Ilford.	The Urban District Council.	John W. Benton, Esq., Clerk to the Council, 3, Cranbrook Road, Ilford.
Ilfracombe Electric Lighting Order. The Urban District of Ilfracombe.	The Urban District Council.	Messrs. Baker & Co., 22, Great George Street, Westminster, S.W.
King's Norton Electric Lighting Order. The Parishes of King's Norton and Northfield in the Rural District of King's Norton.	The Rural District Council.	Messrs. Bircham and Co., 46, Parliament Street, Westminster, S.W.
Kingswinford Electric Lighting Order. The Rural District of Kingswinford.	The Rural District Council.	Messrs. Baker & Co., 22, Great George Street Westminster, S.W.
Leatherhead Electric Lighting Order. The Urban District of Leatherhead.	The Urban District Council.	Messrs. Sherwood and Co., 7, Great George Street, Westminster, S.W.

Title of order and description of area.	Name of promoters.	Agents.
Leigh-on-Sea Electric Lighting Order. The Urban District of Leigh-on-Sea.	The Urban District Council.	Messrs. R. W. Cooper & Sons, 5, Victoria Street, S.W.
Lewes Corporation Electric Lighting Order. The Borough of Lewes.	The Corporation.	Messrs. Renshaw, Kekewich, & Smith, 2, Suffolk Lane, Cannon Street, E.C.
Lowestoft Electric Lighting Order. The Borough of Lowestoft.	The Corporation.	Messrs. Sharpe & Co., 9, Bridge Street, Westminster, S.W.
THE COUNTY OF LONDON:		
Bermondsey Electric Lighting Order. The Parish of Bermondsey.	The Vestry.	Frederick Ryall, Esq., Town Hall, Spa Road, Bermondsey, S.E.
Bermondsey, Rotherhithe, Greenwich, and Lewisham Electric Lighting Order. The Parishes of Bermondsey and Rotherhithe and the Districts of Greenwich and Lewisham.	County of London and Brush Provincial Electric Lighting Company, Limited.	Sydney Morse, Esq., 4, Fenchurch Avenue, E.C.
Bethnal Green, Poplar, and Whitechapel Electric Lighting Order. The Parish of Bethnal Green and the Districts of Poplar and Whitechapel.	County of London and Brush Provincial Electric Lighting Company, Limited.	Sydney Morse, Esq., 4, Fenchurch Avenue, E.C.
Holborn District Electric Lighting Order. Portion of the Holborn District.	Charing Cross and Strand Electricity Supply Corporation, Ltd.	Messrs. Wyatt and Co., 28, Parliament Street, Westminster, S.W.
Holborn and St. Giles Electric Lighting Order. Portion of the Holborn District, the District of St. Giles, Lincoln's Inn, Gray's Inn, Staple Inn, and Furnival's Inn.	County of London and Brush Provincial Electric Lighting Company, Limited.	Sydney Morse, Esq., 4, Fenchurch Avenue, E.C.
Lewisham District Electric Lighting Order. The District of Lewisham.	The District Board of Works.	Templer L. Down, Esq., 3, Pope's Head Alley, Cornhill, E.C.
Lewisham Electric Lighting Order. Portion of the Parish of Lewisham.	Great Western Electric Light and Power Company, Limited.	Messrs. Walter Webb and Co., 23, Queen Victoria Street, E.C.
St. Giles District Electric Lighting Order. The District of St. Giles.	Charing Cross and Strand Electricity Supply Corporation, Ltd.	Messrs. Wyatt and Co., 28, Parliament Street, Westminster, S.W.
St. Marylebone Electric Lighting Order. The Parish of St. Marylebone.	The Vestry.	Messrs. Sherwood and Co., 7, Great George Street, Westminster, S.W.
St. Marylebone Electric Lighting Order. The Parish of St. Marylebone.	County of London and Brush Provincial Electric Lighting Company, Limited.	Messrs. Milner & Bickford, 1, Great Tower Street, E.C.
St. Marylebone Electric Lighting Order. The Parish of St. Marylebone.	Marylebone Electric Supply Company, Limited.	Sydney Morse, Esq., 4, Fenchurch Avenue, E.C.
Maidenhead Electric Lighting Order. The Borough of Maidenhead.	The Corporation.	Messrs. Sharpe & Co., 9, Bridge Street, Westminster, S.W.
Margam Electric Lighting Order. The Urban District of Margam.	The Urban District Council.	Messrs. Baker & Co., 22, Great George Street, Westminster, S.W.
Melton Mowbray Electric Lighting Order. The Urban District of Melton Mowbray and the Parishes of Sysonby, Welby, Eye Kettleby, Burton Lazars, and Thorpe Arnold, in the Rural District of Melton Mowbray.	Melton Mowbray Electric Light Co., Limited.	Messrs. Rees & Frere, 5, Victoria Street, Westminster, S.W.
Middlesbrough Corporation Electric Lighting Order. The Municipal Borough of Middlesbrough.	The Corporation.	Messrs. Durnford & Co., 38, Parliament Street, Westminster, S.W.
Midland Electric Power Distribution and Lighting Order. The Boroughs of Walsall, Wednesbury, West Bromwich, and Wolverhampton, the Urban Districts of Bilston, Coseley, Darlaston, Heath Town, Rowley, Regis, Sedgley, Short Heath, Smethwick, Tipton, Wednesfield, and Willenhall, and the Rural District of Walsall, in the County of Stafford; and the Borough of Dudley, and the Urban District of Oldbury, in the County of Worcester.	Midland Electric Corporation for Power Distribution, Limited.	Messrs. Sherwood and Co., 7, Great George Street, Westminster, S.W.
Michelstown Electric Lighting Order. The Town of Michelstown.	The Michelstown Guardians.	Messrs. W. and W. M. Bell, 27, Great George Street, Westminster, S.W.
Montrose Electric Lighting Order. The Royal Burgh of Montrose.	The Corporation.	Messrs. Clarkson and Toovey, 98, Great Tower Street, E.C.
Norwich (Extension) Electric Lighting Order. The Parishes of Thorpe St. Andrew, Postwick, Sprowston, Old Catton, Hellesdon, Costessey, Bowthorpe, Colney, Cringleford, Intwood, Keswick, Markshall, Arminghall, Trowse Newton, and Bixley, and and the Shirehall and Castle Ditches, Norwich.	Norwich Electricity Company, Limited.	Messrs. Waterhouse and Co., 1, New Court, Lincoln's Inn, W.C.
Nuneaton Electric Lighting Order. Portions of the Parishes of Nuneaton and Chivers Coton.	Nuneaton Electric Company, Ltd.	Cecil F. Twist, Esq., 5, Bedford Row, W.C.
Oldbury Electric Lighting Order. The Urban District of Oldbury.	The Urban District Council.	Messrs. R. W. Cooper and Sons, 5, Victoria Street, S.W.
Ossett Electric Lighting Order. The Municipal Borough of Ossett.	The Corporation.	Messrs. Baker & Co., 22, Great George Street, Westminster, S.W.
Partick Electric Lighting Order. The Burgh of Partick.	Kelvinside Electricity Company, Limited.	Messrs. Burchell and Co., 5, The Sanctuary, Westminster, S.W.
Penarth Electric Lighting Order. The Urban District of Penarth.	Penarth Electric Lighting Company, Limited.	J. C. Ball, Esq., 3, Victoria Street, Westminster, S.W.
Perth Electric Lighting Order. The Parliamentary Burgh of Perth.	The Commissioners of the Burgh.	Messrs. Wm. Robertson & Co., 45, Parliament Street, Westminster, S.W.
Peterborough Electric Lighting Order. The Municipal Borough of Peterborough.	Peterborough Electric Light and Power Company, Limited.	Messrs. Clarkson and Toovey, 98, Great Tower Street, E.C.
Prescot District Electric Lighting Order. The Urban District of Huyton-with-Roby.	British Insulated Wire Company, Limited.	Sidney Morse, Esq., 4, Fenchurch Avenue, E.C.
Preston (Extensions) Electric Lighting Order. The Urban District of Fulwood, and the Townships of Broughton, Lea Ashton Ingol and Cotam, Woodplumpton, Barton, and Penwortham, in the Rural District of Preston.	National Electric Supply Company, Limited.	Francis H. White, Esq., 7, Bedford Row, W.C.
Ramsgate Electric Lighting Order. The Borough of Ramsgate.	Electric Supply Corporation, Ltd.	Messrs. Deacon and Co., 9, Great St. Helen's, E.C.
Rawmarsh Electric Lighting Order. The Urban District of Rawmarsh.	The Urban District Council.	Messrs. Baker & Co., 22, Great George Street, Westminster, S.W.
Rochdale Electric Lighting Order. The County Borough of Rochdale.	The Corporation.	Messrs. Dyson & Co., 9, Great George Street, Westminster, S.W.

Title of order and description of area.	Name of promoters.	Agents.
Rotherham Corporation Electric Lighting Order. The Municipal Borough of Rotherham.	The Corporation.	Messrs. Baker & Co., 22, Great George Street, Westminster, S.W.
Rothesay Electric Lighting Order. The Burgh of Rothesay.	The Corporation.	Messrs. Loch & Co., 36, Great George Street, S.W.
Royal Leamington Spa Electric Lighting Order. The Borough of Royal Leamington Spa.	The Corporation.	Messrs. Sharpe & Co., 9, Bridge Street, Westminster, S.W.
Royal Leamington Spa Electric Light and Power Order. The Borough of Royal Leamington Spa.	Midland Electric Light and Power Company, Ltd.	Messrs. Smith, Pinsent & Co., 6, Bennett's Hill, Birmingham.
Ryde Electric Lighting Order. The Borough of Ryde.	Ryde Electric Light and Power Company, Ltd.	Messrs. Clarkson and Toovey, 98, Great Tower Street, E.C.
St. Albans Corporation Electric Lighting Order. The City of St. Albans.	The Corporation.	Messrs. Rees and Frere, 5, Victoria Street, Westminster, S.W.
St. Anne's-on-the-Sea Electric Lighting Order. The Urban District of St. Anne's-on-the-Sea.	The Urban District Council.	Messrs. Baker & Co., 22, Great George Street, Westminster, S.W.
Shrewsbury Electric Lighting Order. The Borough of Shrewsbury.	The Corporation.	Messrs. Sharpe & Co., 9, Bridge Street, Westminster, S.W.
Smethwick Electric Lighting Order. The Urban District of Smethwick.	The Urban District Council.	Messrs. R. W. Cooper and Sons, 5, Victoria Street, Westminster, S.W.
Stoke-upon-Trent Electric Lighting Order. The Borough of Stoke-upon-Trent.	The Corporation.	Messrs. Sharpe & Co., 9, Bridge Street, Westminster, S.W.
Warrington Electric Lighting Order. The Municipal Borough of Warrington.	The Corporation.	Messrs. Baker & Co., 22, Great George Street, Westminster, S.W.
West Bromwich Corporation Electric Lighting Order. The County Borough of West Bromwich.	The Corporation.	Messrs. R. W. Cooper, and Sons, 5, Victoria Street, Westminster, S.W.
Westgate-on-Sea Parish Electric Lighting Order. The Parish of Westgate-on-Sea.	The Isle of Thanet Rural District Council.	R. E. H. Fisher, Esq., 9, New Inn, Strand, W.C.
Weston-super-Mare Electric Lighting Order. The Urban District of Weston-super-Mare.	Weston-super-Mare Electric Light and Power Syndicate.	Messrs. Robbins, Billing & Co., Surrey House, Victoria Embankment, W.C.
Weymouth and Melcombe Regis Electric Lighting Order. The Borough of Weymouth and Melcombe Regis.	The Corporation.	Messrs. Dyson & Co., 9, Great George Street, Westminster, S.W.
Whiston Rural District Electric Lighting Order. The Rural District of Whiston.	The Rural District Council.	Sydney Morse, Esq., 4, Fenchurch Avenue, E.C.
Willesden Electric Lighting Order. The Parish of Willesden.	The Urban District Council.	Messrs. Holmes, Greig & Greig, 18, Abingdon Street, Westminster, S.W.

ON THE EXTERNAL FIELD OF HELICALLY MAGNETISED RINGS.*

By W. M. MORDEY.

On the subject of some experiments by the present writer relating to ring on armature conductors, enclosed or nearly enclosed in iron, Prof. H. du Bois contributed an article in the *Electrotechnische Zeitschrift* of August 19th last, in the course of which attention was particularly directed to a phenomenon of ring magnets. Prof. du Bois writes:—"*A ring-magnet experiences a side thrust when in an external field whose lines of force are in the same plane as the ring; and conversely it exerts a thrust in the opposite direction upon the supporter of the external field.*" "This deduction," he adds, "so astonishing at first sight, I have proved to be verified by experiment." As its author gives the emphasis of italics to this passage, it may be well to submit what appears to be the explanation, as the present writer chanced to come across the effect in question a good many years ago. It is, as Prof. du Bois says, rather astonishing at first sight, but the explanation seems to be quite simple. The external field is caused by the advancing or longitudinal constituent of the helix. Magnetically a helix traversed by current acts as a series of rings, but, in addition, it has a minor magnetising effect, at right angles to that of the rings, due to the advance of the conductor from end to end of the helix. Thus, a helix bent into a ring or wound about an annular core, forms an endless or ring-magnet when traversed by current. But in addition to this main effect, the faces of the ring, regarded axially, present N. and S. polarity respectively, the whole closed helix acting externally (so far as this subsidiary effect is concerned), and as regards external fields, as a simple loop or ring of conductor carrying current. This may be illustrated by a lines-of-force figure, taken from a ring helically wound with a single layer of winding. In such a figure, the lines of force radiate from the centre or axis of the ring at right angles to the axis of the spiral—they represent portions of closed lines of force which enclose the axis of the spiral. In a helix wound with two layers, one forward, the other back, the external magnetising effect due to this cause is *nil*. In a single layer (or simple) helix, this external effect may be neutralised by returning the wire along the axis of the helix.

A simple straight helix acts externally as a straight conductor.

A flat spiral acts like a disc or wheel, or as a number of radial conductors in one plane traversed by current passing from or to the centre.

* From the *Philosophical Magazine* for December, 1897.

UNIONISM IN 1851.

Engineering has been raking up records of the old unionism which it has lately been the habit to extol as something very superior to the new unionism. Our contemporary shows clearly that in the year 1851 matters were much as they are to-day. A manifesto of December 24th, 1851, is quoted. It might have been penned by Mr. Barnes. Interference with, or dictation to employers, is specially disclaimed, but overtime and piecework is demanded to be abolished, and there are the stock arguments as to the injury to health and the interference with the intellectual and moral growth of the men.

There was a lockout in 1852. This was the immediate outcome of a Masters' Federation, resulting from an attempt to compel an Oldham firm to abolish piecework, and to stop the working by one man of more than one machine, and also to stop unskilled labour. The lockout was announced for January 10th, 1852, the strike having taken place on January 1st.

In every detail the dispute proceeded on all fours with the present one, save that the Employers' Federation only re-engaged men who would forswear the union, and the union was fairly well smashed, the lockout lasting until April. All its funds had gone, but it lost few members, only some 200 between January and June of 1852, though by the end of the year its members had fallen off by about 2,000, or, say, 20 per cent. The same demands by the men, and the same examples of interference, seemed to characterise this earlier strike, and the special vigour of the attack upon employers caused them to combine. But what was the final result? In 1855 the A.S.E. was again as strong as ever, but the Employers' Federation had perished of atrophy, its units reverting to their state of selfish isolation. Thus it was that in 1872 the plan of crushing employers in detail was enabled to secure victory.

Our contemporary quotes "The strong man armed keepeth his goods in peace," and the unionists know this, and have kept the fact in view for 50 years, keeping their eye for ever on the goal, undiverted by victory or defeat. In 1851 they snatched for a prize and missed it. In 1872 they got their prize. They have probably missed their game this time, but if the employers disband, they will surely try again. But things to-day have one great difference. Foreign competition is now with us. Previously it has been an entirely negligible quantity. It is so no longer, and it is to foreign competition acting on the employers that federation has been brought about. The objections in the past to the men's interference have been based on the difficulty of securing correspondingly increased prices for manufactures. But the increased price had to be paid, and was paid. To-day the increased price cannot be asked, but the foreigner will get the work. Hence the Federation, and the certainty that no longer can the policy of dawdling over work be carried on. The operation and details of the present strike may resemble those of 1851-2, but the environment is now changed, and though eight hours will come about in its proper time, it will not be before workmen understand the necessity of maintaining output—not of keeping it down.

A NEW TRANSMISSION DYNAMOMETER.*

By W. E. DALBY, M.A., B.Sc., Assoc.M.Inst.C.E.

In transmission dynamometers in which the deformation of a spring was used to measure the work being transmitted, the mechanism might be divided into two parts: (1) The measuring-springs, and the apparatus fixing them to the several parts of the dynamometer; and (2) the apparatus used to measure the deformation of the spring. The paper treated of a new device for measuring the deformation of the spring.

* Institution of Civil Engineers, December 21st, 1897.

The deformation of the spring was in general communicated to two pieces of the dynamometer, causing relative angular displacement between them. Thus, if one end of the spring was fixed to a pulley and the other end to the shaft on which the pulley was mounted, the relative angular displacement would be between the pulley and the shaft. To measure this whilst the pulley and shaft were rotating, a sprocket-wheel was fixed to the pulley and another of equal diameter to the shaft. Over these an endless band was placed, arranged to form two loops, the parts of the band forming one loop leading the one to the sprocket-wheel and the other to the opposite side of the other sprocket-wheel. In these loops were placed guide-pulleys, mounted in frames, constrained by a slide to move in the direction of the band. A relative angular displacement of the sprocket-wheels was necessarily accompanied by a relative linear displacement of the guide-pulleys in the loops proportional to the torque acting between the shaft and pulley, and by suitably calibrating a scale to measure their distance apart this torque, or change in torque, might be read off directly.

To obtain a good fit, and yet at the same time avoid any sticking of the slide, the frame carrying the guide-pulleys had only six properly arranged points of contact with a group of three bars forming the slide, and to control the motion of the pulleys in any position and constrain them to follow the motion of the loops, a spring was arranged to act on a cord connecting the two frames in such a way that the guide-pulleys were always compelled to sit in their respective loops, the tension on the spring causing them to do so, being constant.

Two dynamometers had been made on these principles for the engineering laboratory at Cambridge. One was arranged on a main driving shaft, the dynamometer being formed by connecting a pulley driving a dynamo to the shaft by means of a spring, a sprocket-wheel was fixed to the shaft, and another of equal diameter was fixed to the pulley-boss. An endless steel band passed over the sprocket-wheels so as to form the loops described was used to operate two guide-pulleys mounted in frames, free to slide in the direction of motion of the band. This, the apparatus for measuring the torque, was placed several feet below the shaft in a convenient place for observation. A second dynamometer was made on the same principle, but arranged to be self-contained. Any machine could be driven through it, and the power given to the machine directly observed. The dynamometer was used to measure the power given to a dynamo. Measurements were made of the work required to overcome the belt friction, journal friction, of the work lost in hysteresis and eddy currents, and of the efficiency of the dynamo at different outputs.

NEW PATENTS AND ABSTRACTS OF PUBLISHED SPECIFICATIONS.

NEW PATENTS.—1897.

[*Compiled expressly for this journal by* W. P. Thompson & Co., *Electrical Patent Agents*, 322, *High Holborn, London, W.C., to whom all inquiries should be addressed.*]

30,065. "Improvements in key switch holders for incandescent electric lamps." J. M. Huisman and H. C. Gover. Dated December 20th.

30,085. "Improvements in electrical contact devices." B. Doyle and H. V. Thirkell. Dated December 20th.

30,089. "An improved process for preparation of an electric paste accumulator." E. Kosel. Dated December 20th.

30,135. "An improvement in vehicles driven by oil engines in connection with electric motors actuated by accumulators." A. L. Fyfe. Dated December 20th.

30,157. "Improvements in and connected with the manufacture of electrical cable or conductor conduits." A. Musker and F. J. P. Cheesbrough. Dated December 21st.

30,205. "Improvements in coin-controlled mechanism for electric and other meters." W. F. Browne. Dated December 21st. (*Complete.*)

30,211. "Improvements in and relating to insulating blocks for electric conductors." W. P. Thompson. (J. Jungbluth, Germany.) Dated December 21st. (*Complete.*)

30,221. "An improved electric fuse and machine for the manufacture thereof." N. Schmitt. Dated December 21st. (*Complete.*)

30,246. "Improvements in arc lamps for projection." L. Stuart and J. H. Barton. Dated December 21st.

30,247. "An improved centreing motion for arc lamps and lime-light jets." J. Stuart and J. H. Barton. Dated December 21st.

30,253. "An improved electro-chemical explosive device." H. H. Lake. (G. Cornara, Italy.) Dated December 21st.

30,256. "Improvements in electrical resistances." A. J. Marquand and F. G. Treharne. Dated December 21st.

30,259. "A method or methods for controlling a mechanism or mechanisms by means of electric or electro-magnetic waves of high frequency." E. Wilson and C. J. Evans. Dated December 21st.

30,264. "Improvements in and relating to windings for polyphase machines." The British Thomson-Houston Company, Limited, and H. M. Hobart. Dated December 22nd. (*Complete.*)

30,275. "Improvements in dynamo-electric machines." T. E. Weaver. Dated December 22nd.

30,277. "A porcelain insulator disc for capped incandescent lamp-holder." W. D. Hassall. Dated December 22nd.

30,295. "The automatic locking lever and lifting lever combination for electrical lifts, cranes, or other machinery." C. E. B. Holt. Dated December 22nd.

30,299. "Improved means for making electrical connections upon railway trains." J. E. Duckworth. Dated December 22nd.

30,341. "Improvements in and relating to electric smelting furnace." W. Antrobus. Dated December 22nd.

30,347. "Improvements in electrical arc lamps." E. P. L. Moss and L. C. A. Pottier. (Date applied for under Patents, &c., Acts, 1883, Sec. 103, November 3rd, 1897, being date of application in France.) Dated December 22nd.

30,364. "Improvements in phase transformers for electric currents and the application of the same to monophase electric motors." E. B. Wedmore. Dated December 22nd.

30,393. "An electro-mechanical dancing marionette figure in combination with rubber rotating sphere for advertising purposes and such like." J. G. Knight. Dated December 23rd.

30,441. "Improvements in primary and secondary galvanic batteries." C. L. R. E. Menges. Dated December 23rd.

30,445. "Apparatus for simultaneously connecting a number of pairs of electric conductors." Siemens Bros. & Co., Limited, and E. Holmes. Dated December 23rd. (*Complete.*)

30,447. "Improvements in supplying electrical energy to railways worked by alternating currents." Siemens Bros. & Co., Limited. (Siemens & Halske, Actien-Gesellschaft, Germany.) Dated December 23rd.

30,470. "An improved electricity meter shelf-fixing, or box and main connection board or box combined." F. W. E. Jones. Dated December 24th.

30,476. "Improvements in and connected with electric traction." H. W. Handcock and A. H. Dykes. Dated December 24th.

30,494. "Improvements in the armatures of induction motors." W. L. Wise. (The Maschinenfabrik Oerlikon, Switzerland.) Dated December 24th.

30,544. "Improvements relating to the electric welding of tubes and to apparatus therefor." O. Parpart. Dated December 24th.

ELECTRICAL PATENTS OF 1884, EXPIRING IN JANUARY, 1898.

We are informed by Messrs. W. P. Thompson & Co., that about 90 applications for electrical patents were filed in the month of January, 1884. Only two of the patents granted for these applications have been maintained to run their full length of term, viz., 14 years, and being of some interest we give short abstracts below.

551. "A new or improved process and apparatus for the extraction of metals from their chlorides or fluorides." L. A. Groth. (R. Cratzee, Hanover, Germany.) Dated January 3rd, 1884. The object is to obtain metals from their chlorides or fluorides. The metallic melting pot used contains an insulating case with which it communicates by means of holes; this case contains the positive electrode while the melting forms the negative. Rods of the metal, to be reduced with carbon, are placed beside the positive electrode in the insulating case, an inert or reducing gas is brought to the pot, which is provided with an outlet. The chlorine or fluorine passes out of the insulating case through a pipe near the top. 2 claims.

2,285. "Improvements in holders for incandescent electric lamps." C. Darnfeld. Dated January 28th, 1884. Consists of the construction of holders for incandescent electric lamps, the object being to enable the lampholders to be conveniently screwed on to gasoliers, chandeliers, &c., to fit the conducting wires in the lampholder in a commodious way, to protect the same from contact or any external disturbance, as well as to fix the lamp itself into the holder in the simplest way ensuring contact with the conductor. 3 claims. This patent was amended on February 6th, 1890.

ABSTRACTS OF PUBLISHED SPECIFICATIONS.

[*Copies of any of these Specifications may be obtained of* Messrs. W. P. Thompson & Co., 322, High Holborn, W.C., *price, post free*, 9d. (*in stamps*).]

1896.

16,270. "Improvements in secondary electric batteries." M. O. A. Garreau. Dated July 22nd, 1896. The plates or electrodes consist of a grid or framework, each rectangular space in which is filled with strips of lead alternately of a flat and corrugated shape. These strips are united across their centre by autogenous soldering. The plates are wrapped in parchment paper and mounted on insulating legs.

17,906. "Improvements in crossings of electric conductors for electric railways and tramways." A. T. Snell, C. E. Grove and A. F. Hills. Dated August 12th, 1896. Relates to the arrangement of conductors at cross-over roads on lines using a three-wire system. An insulated conductor at the crossing is placed above or below the working conductors, and electrically connected permanently, or through switches, with one side of the system, and the current is taken to the locomotive or motor vehicle through additional brushes and switches thereon.

THE
ELECTRICAL REVIEW.

VOL. XLII. JANUARY 14, 1898. No. 1,051.

CONTENTS:

THE ELECTRICAL REVIEW.

Published every FRIDAY, Price 4d.

The Oldest Weekly Electrical Paper. Established 1872.

TO BE OBTAINED BY ORDER FROM ANY NEWSAGENT IN TOWN OR COUNTRY.

OFFICE:—4 LUDGATE HILL, LONDON.

Telegraphic Address: "AGEEKAY, LONDON." Code A B C.
Telephone No. 963 Holborn.

ALL Letters should be addressed to the Proprietors, H. Alabaster, Gatehouse & Co.

ADVERTISEMENT RATES ON APPLICATION.

The "Electrical Review" is the recognised medium of the Electrical Trades.

SUBSCRIPTION RATES.—In *Great Britain*, Post Free per Year, 19s. 6d. To all *other countries*, per Year, £1 4s.

BINDING.—Subscribers' numbers bound, including case, for 4s. each volume.

CASES.—Cloth Cases for Binding can be had, price 2s. 6d. each.

READING CASES, to hold from One to Twenty-six Numbers until the Volume is complete for Binding, can now be had from the Publishers, Price 6s. or Free by Post (in Great Britain), 6s. 6d.

FOREIGN AGENTS.—*New York:* D. VAN NOSTRAND, 23, Murray Street. *Paris:* VEUVE J. BOYVEAU, 22, Rue de la Banque. *Berlin:* ASHER & Co., 5, Unter den Linden.

Cheques and Postal Orders (on Chief Office, London) to be made payable to MR. H. ALABASTER, 4, Ludgate Hill E.C.

THE STRIKE.

ONE is apt to lose sight of the heart of a matter which is daily encumbered with so many side issues. The recent Conference proved a deplorable failure, but it has been of service. It has shown the general public who are at all interested in the question that the engineering employers have all along meant what they said when they declared they would not budge on the question of hours and of management. The public have also been made aware that the men's representatives accepted everything except the 54 hours, and would have ordered the men back to work if the hours had been made 51. The public are thus face to face with the plain fact that the only point at issue in the opinion of the men's executive is a matter of three hours a week. From what we can gather the public knows that foreigners work more than nine hours a day; they know that in America the Saturday half-holiday does not exist, and they are not credulous of the working man when he calls his employer a tyrant. For many years the British workman has been the butt of the comic papers, and has been chiefly in touch with the public in the form and guise of the common plumber. All householders know the plumber and his devious ways. Now, would it surprise the general public to know that the plumber is no worse than any other class; that he is the exact counter part of the great democracy of which, say, Mr. and Mrs. Sidney Webb write in such glowing terms. The plumber is simply a workman who spends as much time as he can upon his work, and thus he forms a very valuable comparison to lay before the outside public as a sample of the type of man which obeys the orders of trades union bosses and restricts production.

We commend, therefore, the plumber in all his parts to the sympathisers of the down-trodden and tyrannised men as a sample of the quality of working against which the employers have had at last to strike. The position is now plain. Trades unionism is trying to strengthen itself by drawing on its members all over the country, as well as accepting the help of foreign workmen who hope to get all the work. Employers have not in the past been prone to federate. In doing so they have been compelled by the men, and the result has been disastrous to the men, who should pause before they give any pretext to the employers to similarly extend the area of their federation over other than the trades at present involved. We are not of those who wish to see too much federation of capital, but we are equally averse to see a federation of ignorance, and that is what the present practice of trades unionism has come to imply.

It is said that outsiders see most of a game, and when viewed from a distance, no doubt the present struggle is seen in clearer perspective than it appears to those of us in the midst of it. In the *Engineering and Mining Journal*, a writer, whom we believe to be a man of considerable attainments in all commercial and economic matters, looks on the employers' demands under the head of freedom of employment, as the recitation of the alphabet of liberty, and when he reads that this is "diametrically opposed to the first principles of trade unionism," he throws in his vote with the London *Times* in denouncing these principles as opposed to common sense. Similarly, also, he perceives the folly of trades union objections to the payment of men according to their ability. Yet he is told that this also is opposed to the sacred principles of unionism

He sees in this attitude of unionism the compulsory discharge of the aged, the infirm, and the cripples, just as we have often pointed out—the abolition, in fact, of the natural kindly sentiment we all recognise in the presence of the one-armed gatekeeper. We well recollect in our own apprenticeship days the face and figure of the old fellow whose name we have forgotten, who sat all day on a block of wood fishing with a magnet in a tray of gunmetal turnings extracting the iron. What it cost to clean this gunmetal was never counted, but it would have paid the firm to throw it away and discharge the man.

The American writer sees that trades unionism is to-day foreign in its aims and purpose from its original inception. He sees how unionism has encroached upon the rights of free contract, and has violated the economic law. He sees that its demands have only stopped short of direct stoppage of business, and that employers have been assumed to be capable of affording all they have conceded to extortion. He states plainly that trades unionism is undermining the prosperity of Great Britain by its short-sighted selfishness.

Commenting upon the truculent statement of the men that if they do drive away English trade they will follow it abroad, he says if they follow it to America they will have to be very different in their behaviour to secure steady employment. They will be glad to work 56 or 60 hours a week, and will speedily be walked out (they say fired out in America) of the shop if they stick at attending several tools at once, while if they loaf about filing or scraping they will not be asked too often if they intend to work all week on a two hours' job. He concludes that the strikers have run against three great first principles which can be warranted to stand the shock, namely:—

(1) Whoever demands more than justice will ultimately fail, and may even as a penalty of failure get less than justice. (2) Destroying the trade of a country is not the way to improve the condition of its operatives. (3) There are two sides to the labour question; and it is high time to consider not merely what the employer pays, but also what he gets for his money.

Mr. Benjamin Taylor, who writes on "The Blight of Trades Unionism," thoroughly denounces its aims and practices. In an article in *Cassier's*, in which he reviews British labour conditions, he give a concise *résumé* of the history of trade disputes during the past few years. "Whom the gods wish to destroy they first make mad" was never so applicable as to the practices of trades unionism. Most of the disputes of late years have been cases of civil wars between different unions on questions of demarcation of work. Furies themselves could scarcely compare with the fury of an engineer who finds a sinful boilermaker with a file in his hand. The different trades unions have fought among themselves over these paltry matters without any thought to the poor employer at all, and one is forced to the conclusion that all the trouble arises from the officials, who are jealous of each other, and endeavour to keep all the work possible for their own members in order to prevent other unions becoming more rich at their expense.

There is an important fact, but one sadly overlooked, that of the workmen as a whole only about one-sixth belong to the unions. We do not learn that the five-sixths are in receipt of less wages than the one-sixth. Yet on the basis of "he who is not for us is against us," we may conclude that the majority do not love the unions, and get along all right with their employers. How, then, can the employers be the tyrants they are represented to be. The real tyrant is the trades union spirit as now understood by the leaders and blindly accepted by the men.

Apart from any smashing of unionism, it is doubtful if the time has not now arrived to utterly annihilate the bogus affair which passes for unionism, and make a clean sweep of the whole crew who mismanage the union business, waste their funds, and bring their members to starvation. If the employers as a result of this present struggle only learn not to hold a candle to the devil by giving way upon any points which are opposed to sound business principles, we think good will arise. Employers in the past are largely to blame for the present condition of affairs. They have given way on an infinity of small points, perhaps none of them in itself of any serious weight, but aggregating to an immense total, and becoming, like Sindbad's old man of the sea, too burdensome to carry further.

Trade union tyranny has become a grinding tyranny; its members have, as a mass, lost all sense of honour and manliness. For exclusiveness, they have excelled the old guilds, whose tactics ruined the great cities of the middle ages. In a free country there is, and ought to be, perfect freedom to combine for lawful objects; but it is contrary to the principles of freedom for a combination to limit the freedom of the outside individual, and to set up lines of demarcation, or use immoral methods of suasion. There must be something rotten in present day unionism, when the ordinary police are unable to preserve every man in safety who is endeavouring peaceably to earn his living. If trades unionism cannot exist without such immoral means, the sooner it is destroyed the better will it be for all. The sober and industrious will profit in larger wages. The drones of the hive will perhaps be driven to mend their ways, and so far will also profit. The only losers will be the fanatics who lead the men in the ways of destruction, and run them against the rocks of the unshakeable principles of truth.

Wattage of Lamps.—The *Canadian Electrical News* draws attention to the wattage of lamps as a matter in which a saving might be effected by central stations. Lamps can be obtained of 60, 54, or 50 watts each. In an average 1,000 light plant probably an average of 6,000 lamp hours per night are supplied. The difference between using 50 watt lamps and 54 watt lamps is 24,000 watt-hours nightly, which is almost 50 horse-power-hours. Putting this at its coal equivalent shows that 50 watt lamps will save about 23 tons yearly over 54 watt lamps, and at $3 this means $69 yearly. In order to use 50 watt lamps it is absolutely necessary to have a very close voltage regulation, and this can be effected by a liberal use of copper and careful attention. Five per cent. interest on $1,400 is $70, and this liberal use of copper will not cost $1,400, so that a net saving will result, not to speak of the increased lamp capacity of the machine.

SOME NOTES ON SINGLE-PHASE MOTORS.

By A. C. EBORALL.

The position of the single-phase motor has very greatly improved within the last two years. Three years ago there were very few motors available, and these had many defects, both in starting and running. This is no longer the case, several types, whose performance leaves little to be desired, being on the market at the present time. That being so, it has occurred to the present writer that the publication of some recent notes of his, bearing on this subject, might possibly be of interest.

The single-phase motors now on the English and Continental markets may be conveniently divided into the following broad divisions:—

I.—*Constant magnetic field motors.*
II.—*Alternating magnetic field motors, and*
III.—*Induction motors.*

I.—Constant Magnetic Field Motors.

The ordinary reversed alternator, which is a typical example of this class, is, from the nature of its design and operation, of but very limited application. The complication of the exciter, and the necessity of bringing the motor up to speed, and synchronising it with the line current before switching-in, precludes its use in most situations where electric power is required. Of course, once having got it running on the load, such a reversed alternator makes a splendid motor for large powers, superior probably to any other, as it possesses the best of regulation, high efficiency, and high power factor, combined with an ability to stand any usual overload. Such a synchronous motor also possesses the very valuable property of acting as a "phase-rectifier," the power factor of the line being improved by simply regulating the motor fields—giving it more excitation than it actually needs for the load, and which is equivalent to the effect of a condenser of large capacity in the circuit. Of course, the over-exciting of such a motor must naturally not be pushed too far, else it may have the effect of causing the motor to run out of step, even when underloaded.

In accordance with what has been said above, synchronous motors of this character have been little used, owing to their difficult operation. In America, one or two installations have been laid down, principally for mill driving, and there are also several on the Continent. The methods of starting usually employed are:—(1) Running up the generator and motor together, giving the latter a start by hand, and exciting the fields from a few accumulators, or (2) running the direct coupled exciter as a motor from a storage battery of small dimensions, and which may also temporarily excite the fields, thus bringing the main unit up to the necessary speed; or, lastly (3), running up motor and exciter by means of one of the self-starting single-phase motors presently to be described. In each case the main unit must start on a loose pulley—and in each case complication and expense.

It may be remarked in passing, that all the later installations of this class have been laid down with polyphase machines, as their performance is in every way as good as that of the single-phasers, while at the same time less copper is required in the line, they are easier to start, and considerably cheaper. Their phase-rectifying properties are also good—in this connection two important Swiss power installations may be instanced in which these properties are satisfactorily utilised—one, on the Hochfelden-Oerlikon transmission, the other the Bremgarten-Zürich line, in each case three-phase synchronous motors running light and much over-excited, helping to annul the inductive drop produced by asynchronous motors running on the same circuit. In the last example the motor is of 250 H.P.—but its use is only rendered necessary by reason of the poor regulation of the generators.

Seeing that single-phase reversed alternators make such good motors when once running, it is not surprising to find that many attempts have been made to make them self-starting without the aid of external devices. These attempts have invariably taken the form of laminating the fields, and passing the supply current both through them and the armature at starting, thus causing the motor to run up to speed as an ordinary series or shunt-wound motor. Synchronism having been attained, the line current would be switched on the armature, and the fields excited by means of a direct current derived from a small commutator placed on the end of the shaft, and which is in electrical connection with the supply leads.

Probably the first commercial motor of this type was one made by Messrs. Brown, Boveri & Co., four or five years ago, and the principle of which is indicated in fig. 1. The

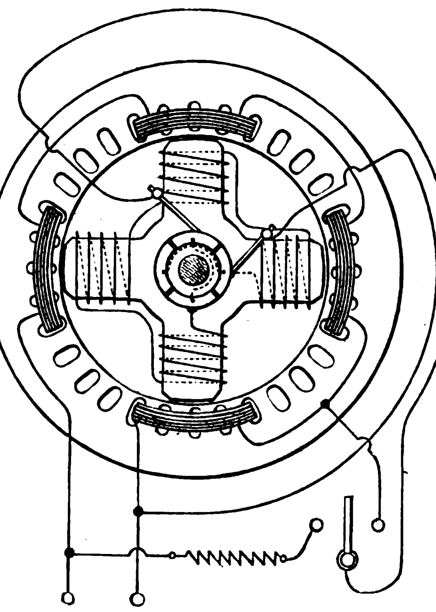

Fig. 1.

stationary armature is hole wound with rectangular coils connected in series, producing N. and S. poles round its inner periphery. The rotating field magnet is built up of star-shaped stampings, the windings being on the arms of the star. These windings may be either connected in series or in two parallels, the two free ends being brought through the shaft to an overhung commutator on one end of it. This commutator has four segments, but opposite segments are connected together (they are one casting, in fact), so that it is virtually a two-part one. Two brushes on a rocker at 90° apart lead the current to it.

The mode of starting up is as follows:—A resistance being in circuit with the fields, the latter are put in parallel with the armature, and the combination switched on the mains. The motor brushes are then shifted right forward through 90°—this being done in order to have the field current in the correct phase with regard to the armature current. The motor will now start to run up, operating as an ordinary shunt motor, and emitting a peculiar note, which changes in tone as the speed approaches synchronism. When very near a synchronous speed, the tone will change to unmistakeable beats. On these being heard, the field resistance is cut out, and the fields put in parallel with one armature coil, when the motor will run right into step and can now be loaded up. The fields are now, of course, receiving a direct current from the commutator. As to the position of the brushes—they are right back at this synchronous speed—they having been gradually shifted back as the motor ran up.

The operation of starting as described above is not nearly so complicated as it sounds, one switch shifting all the connections. In order to avoid an excessive current consumption at starting, such motors were usually started with an auto-transformer, or equivalent device.

It may be of interest to enumerate the many defects of this type of motor, and their causes.

Let the case be considered of the motor starting—an alternating current is running through both fields and armature. Now the self-induction of these is widely different, and hence the lag in the armature circuit is quite different to that in the field circuit. It follows from this that the torque exerted between the two is necessarily insignificant, because the armature current may have its maximum strength at a time when the magnet's field is quite weak. Hence the motor must start on a loose pulley.

If the brushes on the commutator are not in the right position, the motor will not start at all, for the reason given before. They must be right forward, and as the motor comes up to speed, gradually shifted back. This is done to the accompaniment of a great deal of sparking, which, however, practically ceases when the motor is running synchronously on the load.

Again, owing to the considerable air-gap required by such a field magnet, and also to the form of the latter, there is considerable magnetic leakage at all loads, but especially at

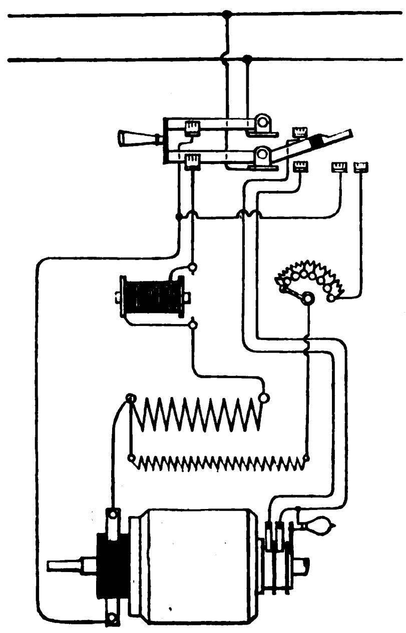

Fig. 2.

starting and heavy loads. As a result the power factor of such a motor is never high, and sometimes a very small quantity indeed.

Overloading a motor of this type to any extent is an impossibility, as it falls out of step, principally owing to leakage.

To sum up the disadvantages of this type of motor:—

1. It must start on a loose pulley.
2. It has dead points at starting.
3. The brushes must be manipulated during starting.
4. There is considerable sparking at all stages of the starting operations.
5. It is very liable to burn out.
6. Its power factor is low.
7. It cannot be overloaded to any extent.
8. It could not be commercially operated at any frequency greater than 60 ~.

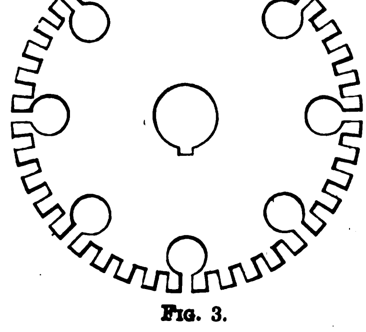

Fig. 3.

The efficiency of these motors can be made high, and this is about the only virtue they have. Owing to their many defects, Messrs. Brown have long since given up their manufacture, but motors identical in design are used for driving the Ferranti rectifiers, and possess all the faults mentioned above to a larger or smaller extent.

Messrs. Ganz & Co., of Buda-Pesth, and the Fort Wayne Company of America, have also worked at the problem of making a synchronous motor self-starting, and have met with a considerable amount of success. The motor of the latter company well merits description, as, taking it all round, it is certainly one of the best single-phase high frequency motors on the English market at the present time. Fig. 2 is a scheme of the windings and connections, and fig. 3 shows the pattern of core disc used for the armature.

(*To be continued.*)

ELECTRIC RAILROADING.

A good deal of nonsense has been uttered from time to time in connection with the development of electric traction for heavy railroad work, and (even ignoring the preposterous dreams of ordinary newspaper men who gaily throw steam locomotives on the scrap heap, and clamour for 150 miles an hour on our present railway tracks) those who presumably ought to know better, have too often been guilty of claims for which no sound basis can be shown—notably by emphasising the so-called fuel economy of stationary compound condensing engines as compared with results obtained from the average steam locomotive. They forget that the coal bill isn't the only or the chief part of a railroad's expense account.

There is, however, on the other hand, no reason why electrical engineers should go out of their way to find fault with electric traction because it apparently cannot, all at once, replace the use of steam locomotives; plenty of people—outsiders—will be ready to discount the advantages of electricity without any help or encouragement from those presumably engaged in advocating its use. We do not, therefore, quite see the object of Dr. Cary T. Hutchinson in his recent remarks before the New York Railroad Club upon the engineering side of the application of electricity to standard railroading; at any rate, his remarks would certainly not apply in this country with the force that they may have in the States.

He thinks that the application of electricity to trunk-line service is no nearer than it was at the time of Edison's first locomotive! By this, of course, he does not imply that electrical appliances have not improved, but that the conditions of railroading have continuously become more onerous; freight trains are heavier, express trains are faster and more frequent, &c.

As stated, this may hold for lines and railway systems like those in the States, where single track is common, and trains are all sandwiched in together on the one track. With us it is becoming a matter of necessity to have a four-track line, with separate tracks for goods or slow passenger, and express services. The more frequently, therefore, that expresses run under such conditions, the more economical would be the use of electric traction for such a service. Moreover, except for the first cost of motor plant, there seems no reason why still greater economy should not follow from the employment of electricity for heavy goods service also. It is because the average goods engine has a considerable amount of shunting and odd jobs of a similar kind to perform, that it manages to burn so much coal in comparison with its straightaway train mileage.

Therefore, if the goods service were also operated by electricity, the greater part of the generating plant would be taken up in providing current for work of this kind, going on for considerable periods. The demands of express traffic would only come on at infrequent intervals, but, as a whole, the power plant should have a very good load factor.

It really seems that electric railroading is very like electric lighting in regard to its application; that is, the greatest economy ensues in the latter when the *whole* of a district or area is supplied with current, and every householder uses it for all his lights. The slow development of such a satisfactory state of things has not deterred the electric light engineer from doing good pioneering work, nor should it in the case of electric traction for railroads. No one expects the North Western, the Great Western, or the Midland, to discard offhand all their fine steam locomotives, and increase the capital accounts by many millions to provide for power houses, third rails, motor cars, and electric locomotives; nor yet has anyone ever proposed to light the whole of one big city simultaneously by means of a single enterprise. The analogy is confessedly not exact, but there is much truth in it, and a step-by-step progress to maximum results may just as conceivably follow from care in choosing the best railway lines for immediate equipment, as in choosing the best areas for lighting.

NEW MODELS OF THE LALANDE OXIDE OF COPPER BATTERY.

The Lalande battery is well known to our readers,* and its inventor is continually making fresh improvements upon it.

The new models, which are simplified and reduced in price, constitute a very important improvement on the old types which were much appreciated; they enable us to avail ourselves in all security and without risk of accidents of the remarkable advantages of this battery, which only consumes its products in proportion to the work furnished; viz., enormous electrical capacity, great output and long duration, perfect constancy.

The oxide of copper is contained in cylindrical jars of perforated sheet iron enclosed in a porous substance without any appreciable resistance; the result is that the metallic deposits on the zinc are almost entirely suppressed, short circuits being thus absolutely avoided.

The zincs, which are simplified in form, are cylindrical in shape, and are hung from the sides of the glass jars. The

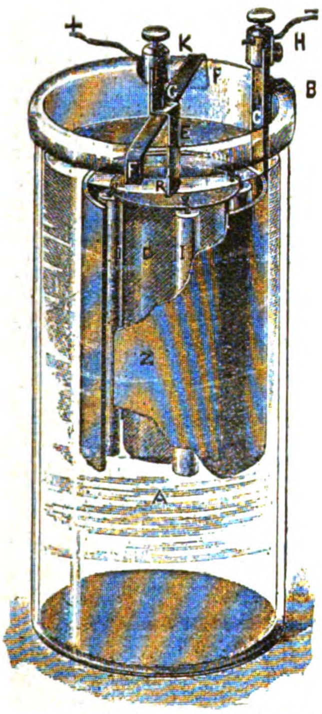

Fig. 1.—Improved Element, 1897, Large Type.

glass jars of the large and medium types are moulded by the Appert process, and are very strong.

The charges of potash for the different types are contained in tins with hermetically-sealed lids, which ensures their preservation for an indefinite period. Moreover, the dissolution of the potash is effected very easily and quickly, without any manipulation and without risk. To obtain it, we pierce with some sharp instrument, one or two little holes in the bottom of the tin opposite the lid; we remove this lid by prising up the projecting rim with a screwdriver, or some other instrument, and replace it by a perforated lid (accompanying each tin), which is fixed in place by a few blows with a hammer. The vessel containing the battery having been filled with the proper quantity of water, the tin of potash is put in upside down, being held to the top by a rod of any kind, a pencil, for instance, which is passed through the ring that is soldered on to the bottom of the tin, and rests on the sides of the glass vessel. The water enters the box through the perforated lid, driving out the air through the holes in the bottom, and soon dissolves the potash which sinks to the bottom of the vessel. When the dissolution is finished, the tin is taken out and thrown away (first shaking it to make sure that it is empty); the liquid is then very carefully stirred by means of a rod. Then, when the electrodes are put in position, the battery is ready to work.

In order to provide against accidents that might be caused in rooms, for instance, by the breaking of the glass vessel containing an element, a protective case of tin may be used, into which the glass vessel can be slipped. Then, in case of breakage, the potash is retained without the function of the element being interrupted.

The large type element (fig. 1) (total height, ·37 m.; diameter, ·18; capacity, 600 ampere-hours; internal resistance, ·03 ohm; continuous normal output, 5 to 6 amperes; forced output, 15 to 20 amperes), comprises a glass vessel, A, a cylinder of amalgamated zinc, Z, which is suspended to the sides of the vessel from a hook, B, fixed to the conducting plate, C, and a depolarising cylinder of oxide of copper, D. The latter has a conducting plate, E, which is bent double, and on which is fixed a round plate of metal, R, supporting four porcelain insulators, I, I, I, I.

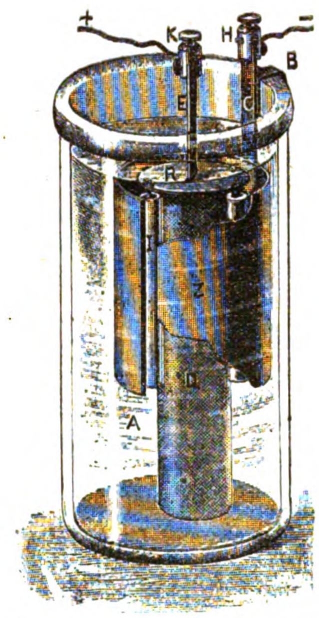

Fig. 2.—Improved Element. 1897, Medium Type.

The cylinder, with its insulators, is supported by a metal cross-piece, F F, provided with a point, G, which passes into a hole in the conducting plate; the insulators keep the electrodes equally distant from one another. The current is taken from the terminals, H and K. The medium model (fig. 2) (total height ·325 m., diameter ·15 m., capacity 300 ampere-hours, internal resistance ·05 ohm, continuous normal output 3 to 4 amperes, forced output 8 to 10 amperes), has a zinc electrode, Z, similar to that of the large model, and like it suspended to the sides of the glass vessel, A. The depolarising cylinder, D, is also placed in the centre of the zinc, Z, from which it is separated by three insulators, I, I, I; this cylinder rests on the bottom of the vessel.

The small type model (fig. 3) (total height ·2 m., diameter ·115 m., capacity 75 ampere-hours, internal resistance ·25 ohm, continuous normal output 1 ampere, forced output 2 to 3 amperes), has a zinc electrode, Z, consisting of a portion of a cylinder, and also the oxide of copper cylinder, D, opposite to it, suspended to the sides of the glass vessel. The zinc is provided with a conducting wire, H, and the cylinder of oxide with a terminal, K.

For the elements to be properly mounted it is necessary that the solution of potash should be mixed with great care, and that it should cover the electrodes of the battery to the depth of 2 or 3 centimetres.

* See *L'Electricien*, 2nd series, Vol. i., 1891, p. 409.

It is advisable, especially for elements intended to last a long time, to cover the liquid with a layer of thick oil to the depth of half a centimetre. The battery requires no other attention; its consumption is only in proportion to its work. The long duration of the elements, which are capable of producing about ten times as much work as other batteries, renders its use really economical.

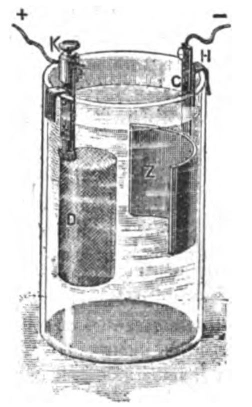

Fig. 3.

The electromotive force of the various elements is from ·8 to ·9 of a volt. Two elements have to be used in place of a bichromate or a Bunsen element.

When the battery is exhausted, its various parts, the zinc, the cylinder of oxide of copper, and the potash being calculated so as to become exhausted simultaneously, must be replaced. The other parts only can be used again after cleaning.

The oxide of copper battery is especially suited to all applications that require a large output and long duration. Amongst the most important may be mentioned the use of the battery for working the induction coils of gas and petroleum engines. Four elements can work the coil of an engine running 10 hours a day, for about a year for the large type and six months for the medium type. Some coils only require three or even two elements. — Un Praticien (*L'Electricien*).

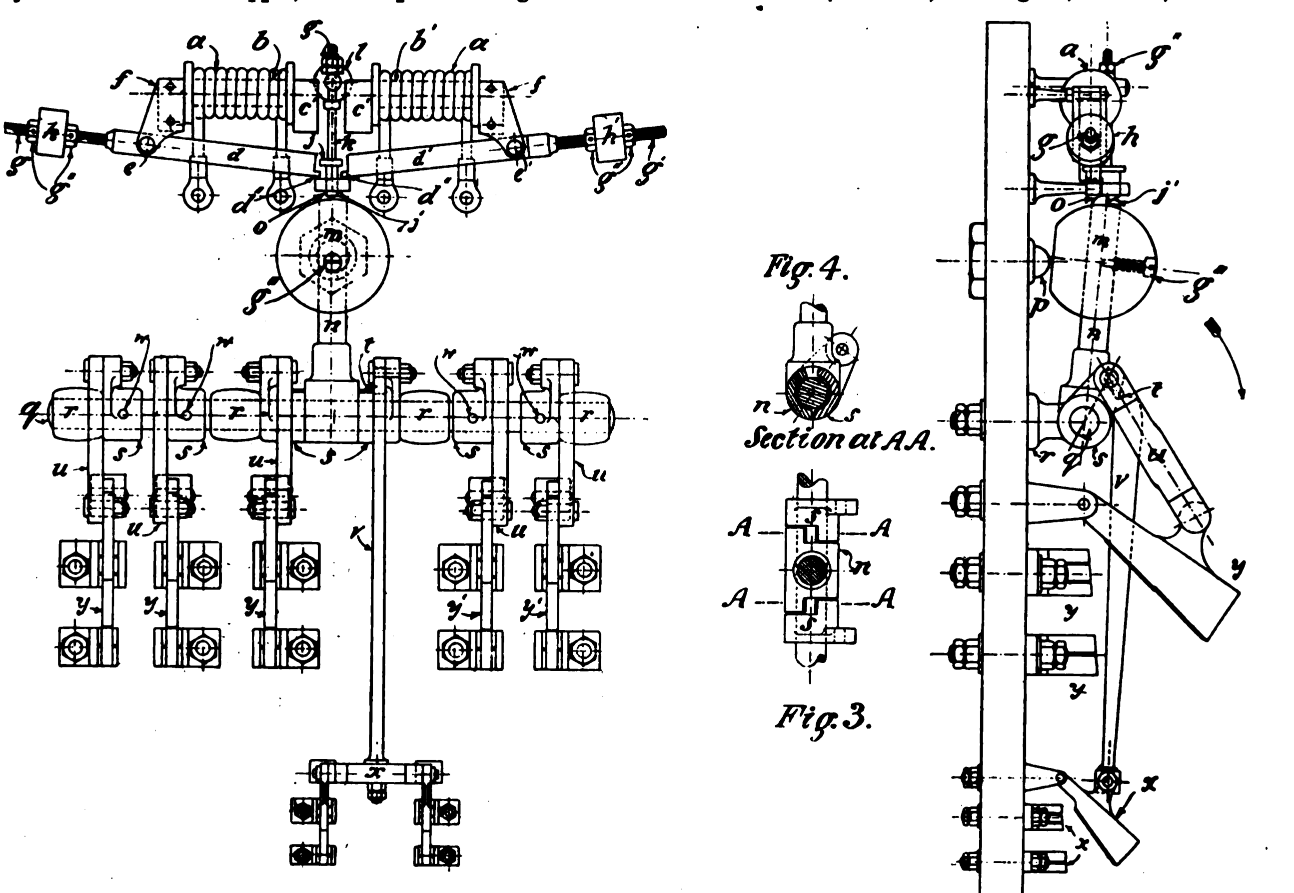

Fig. 1. Sub-Station Transformer Switch Fig. 2.

SUB-STATION TRANSFORMER SWITCH.

To reduce as much as possible the serious item of sub-station expenditure, and risk of the attendant not being on the spot when required, the automatic transformer switch, which is illustrated, has been designed by Mr. A. H. Walton, acting engineer of the Metropolitan Electric Supply Company, Limited. From the illustrations it will be seen that this apparatus has in all six switches—one double-pole switch for the primary, mounted on an independent marble base; two single-pole switches for short-circuiting the solenoids after the switch is brought into action, and three for connecting the transformer on the low tension side of a three-wire system. Its action will be obvious.

Fig. 1 is a front elevation of the automatic switch, showing the full details of the apparatus as arranged for transformers working on a three-wire system, the coils, a a', being in the main circuit, one on each of the outer wires. Fig. 2 shows a side elevation of the same.

Fig. 3 shows point at which the weight operates. Fig. 4 is a section on line A A, fig. 3.

a and a' are electro-magnets, magnetised by the aforesaid electrical energy requiring adjustment, having laminated cores, b and b', with projecting pole-pieces, c and c', suitably shaped for attracting the armatures, d and d', which armatures are pivoted to the pieces, e and e', of the bases, f and f', of the electro-magnets.

The armatures are counterweighted and adjusted by the regulating screws, g and g', which regulate the position of the balance weights, h and h', these weights being locked in any desired position on the screws by the nuts, g'', as shown.

The armatures, d and d', are tongued, as at d'', in order to engage (when being drawn up to the pole-pieces) with the collar piece, j, attached to a spindle, k, whose freedom of motion through the pillar, l, is limited by the collar and nuts, g'', as shown; at the same time the armatures, d and d', are inoperative until they reach the collar, j, thus preventing the uncertain working of the apparatus, and also relieving the armatures, d and d', from any friction, and making the pull of the magnets perfectly constant.

m is an adjustable weight sliding on the tongued bar, n, and locked by the set screw, g''', as shown.

This weight is thrown slightly forward, beyond its centre of gravity, by the India-rubber stop, p, fig. 2.

The object of the tongue, *o*, on bar, *n*, is such that while engaging with the tongue, *j*, it prevents the weight falling further forward by gravity, whilst the current is gradually energising the electro-magnets up to the pre-arranged maximum at which the switch or switches is, or are, set to act.

The bar, *n*, works on a spindle, *q*, running through bearings, *r r r r*, to which spindle the arms, *s s s s s s*, are connected by pins, *w*, keys, or other suitable means.

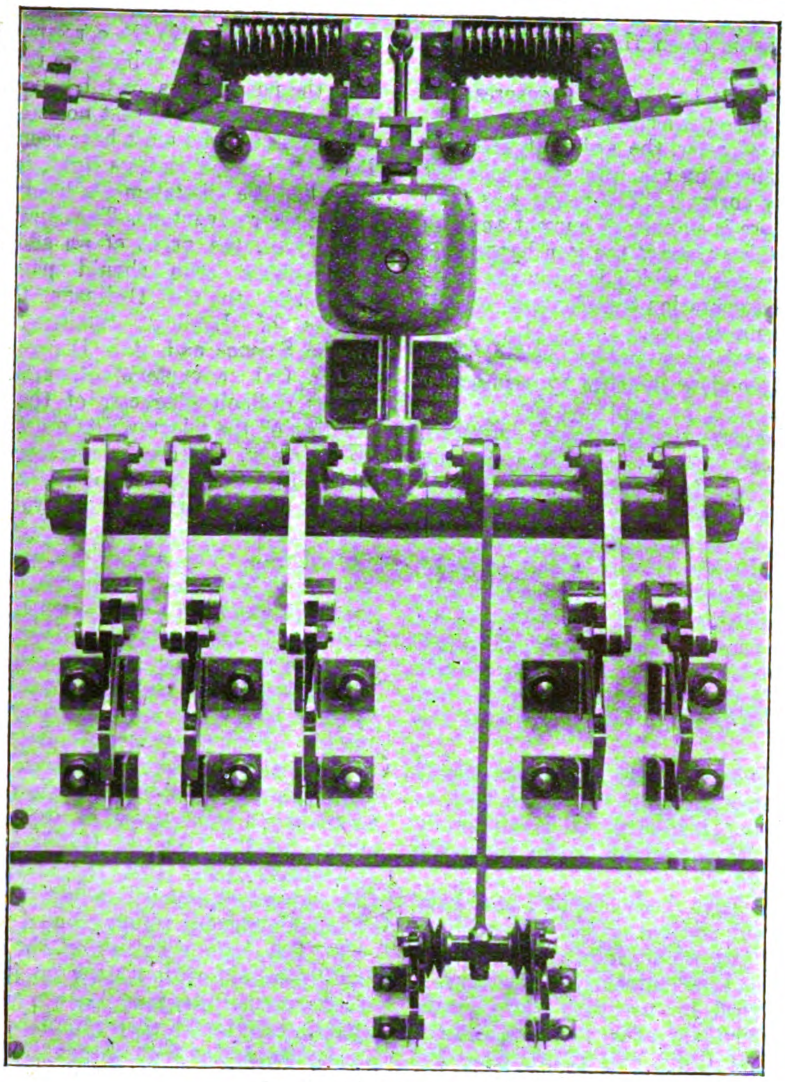
The arm, *n*, is free to move on the spindle, *q*, for a certain distance, so that it may gain sufficient momentum before the moment of actuating the body of the arms, *s s*, on either side of it.

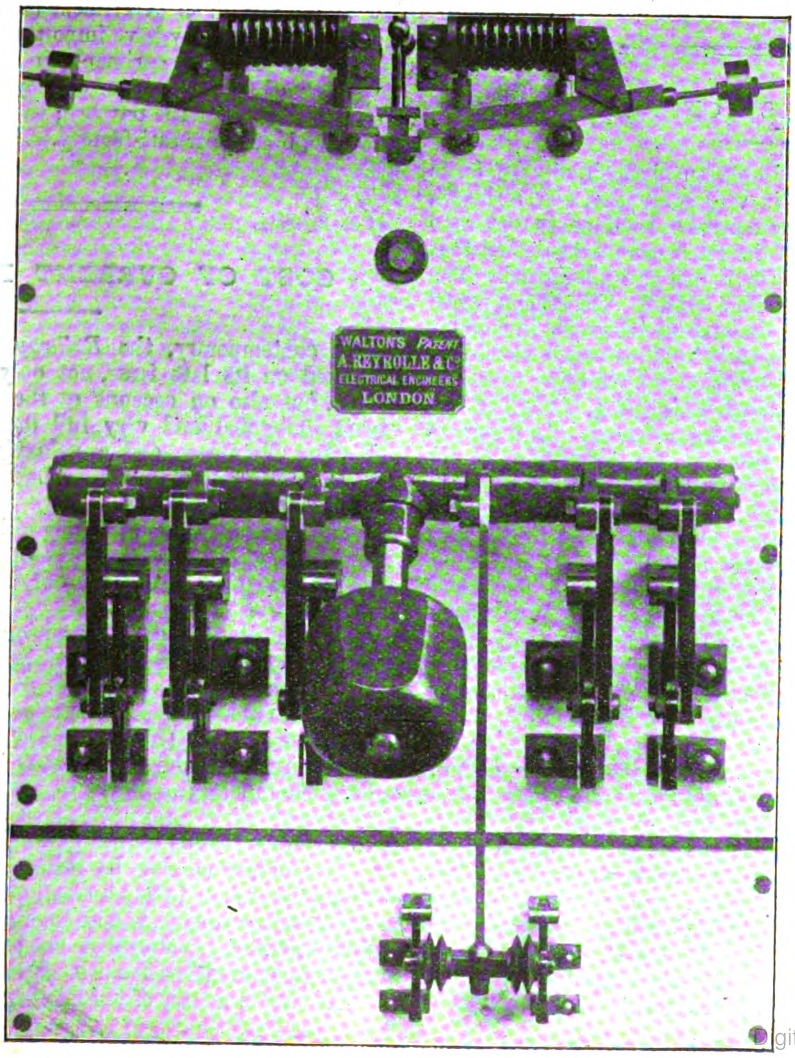
The method of actuating these arms is shown in fig. 3 and fig. 4, in which part of each side, *n*, is cut away, thus showing engaging parts of the arms with *s s*, which are similarly treated. To one of the arms, *s*, is attached a link, *v*, having a slot, *t*, shown dotted in fig. 2; the object of this slot is to enable the link, *v*, to close the small switch shown at *x* in figs. 1 and 2, for closing the primary of the transformer after the larger switches, *y y y y' y'*, have been closed.

The three switches, *y y y*, when closed, introduce the secondary of the next transformer or group of transformers as previously arranged.

The two switches, *y' y'*, are for the purpose of short-circuiting the coils, *a* and *a'*, after they have completed their work, thus saving any loss of energy in same.

It may thus be seen that on any predetermined





amount of current passing through the coils of the electro-magnets, *a* and *a'*, their armatures, *d* and *d'*, are drawn up immediately, thus releasing the weighted arm, *n*, which turns freely for a limited distance on the spindle, *q*.

On the prongs of the clutch, see fig. 3 and fig. 4, engaging the spindle, *q*, at once turns, and being attached by pins, *w*, to the arms, *s s s s s s*, closes first the five larger switches, and then by the means of the pin and slot, *t*, the small switch, *x*, attached to the link, *v*.

In opening the switches the action is the same, and the larger switches open first and the smaller switch opens last.

The chief object and advantage of this arrangement is that owing to the secondary of the transformer being closed first, the rush of current which would occur if the primary were switched in first, is prevented by the iron being magnetised by the secondary coil, and also sparking is greatly reduced when transformers are taken out of circuit.

The links, *w*, figs. 1 and 2, are insulating pieces.

The link, *v*, being metal, is insulated from the small switch at the point, *x*, fig. 1, by means of an insulating bar.

We have had an opportunity, through the courtesy of Mr. Walton, in witnessing the operation of this switch, and it appears to possess many distinct advantages; among them may be mentioned the following:—

1. The action is simple and definite. Once the switch begins to act, it does so thoroughly,

and there is no hunting, as is often the case with automatic apparatus.

2. The short-circuiting of the two solenoids ensures that no energy is absorbed when once the switch is put on.

3. In switching in a transformer, the switch first closes the secondary coil, thus magnetising the iron synchronously with the incoming primary current. The primary is then closed, and by this means there is no rush of current and rise in pressure, which so often takes place if the iron happens to be magnetised the wrong way, and which is often the cause of the breakdown of large sub-station transformers, especially where the working pressure is high.

4. The switch being essentially a gravity switch, good contact is ensured for the secondary switches by adjustment of weight as required.

5. Owing to the particular arrangements already described, the working of the magnets is certain, and the moving armatures, d d', are relieved from friction.

By its use one man can look after many sub-stations; all that he requires to do being to switch the transformers "off" after the load has fallen. In the case of a fog suddenly arising, the central station engineer may rest assured that as many transformers are switched in as are necessary, and all he has to do is to send round and switch them off at his leisure. Nor can the attendant err by leaving in too few transformers for the load, for then each transformer in turn will be automatically switched in by its predecessor until the required load is reached.

It will be noticed that this switch does not automatically cut-out, and no doubt all practical men will agree that, to ensure the sub-station being inspected, it is absolutely essential that there should be something to do when the inspector visits the sub-station.

Several of these switches have been erected, and have been in daily use, in the sub-stations of the Metropolitan Company for many months, and we are informed that their working up to the present has been eminently satisfactory.

The switch shown is designed for use with a 30-kilowatt transformer. The manufacturing of these switches is in the hands of Messrs. Reyrolle & Co. We congratulate Mr. Walton on devising so ingenious and practical a piece of apparatus, and trust it may obtain the success which it merits.

THE POST OFFICE.

The progress which this important branch of the State makes from year to year is very gratifying, and although there may doubtless be very much to be done in order to satisfy the ever exacting public, yet it cannot be denied that such progress as has been made is real and substantial. The reduction in the ordinary postage rate, in the express parcel rate, in the charge for the delivery of telegrams in country districts, &c., have been wholesale reforms which should be much appreciated. The abolition of certain vexatious restrictions have also given much satisfaction, though in this respect there is still room for improvement. In regard to telegraphic and telephonic progress, the completion of the transfer of the telephone trunk lines, hitherto owned by the National Telephone Company, took place early in the year (1897), so that at the present time the whole of the very large network of trunk wires is now exclusively controlled by the Department, and the disadvantage of a divided maintenance is avoided. The extension of the telephone system generally has been continuous, and is still progressing, and this, in conjunction with the work in connection with the telegraph system, must have severely taxed the energies of the very capable staff forming the engineering branch of the Department.

On April 1st the recommendation of the Tweedmouth Commission on Post Office Establishments came into effect, but the dissatisfaction which was expressed by a large body of the staff resulted in a special committee being appointed, which committee recommended certain modifications in the original report, and these have been carried into effect. The modifications, however, did not include any change in the scales of pay which the Tweedmouth Committee had recommended. Whether these scales are really adequate or not we do not express an opinion upon, but in the correspondence which took place in our columns on the subject we think it became quite evident that the public press had been quite misled as to the real facts of the case, and that no attempt whatever was made by the agitators, who must have seen that the public were being led astray, to put matters right, as they doubtless would have done had the misstatements been to their disadvantage, and not to their advantage. The concession of the "double increment," *i.e.*, the grant of an additional increment to those telegraphists who should pass technical examinations equivalent to the Ordinary Grade of the City and Guilds of London Institute, and the Pass Grade of the Science and Art Department, has doubtless been taken full advantage of, and, considering the by no means difficult character of the examinations, a very large number of the telegraphists must have received the increase to their pay. As usual, however, discontented grumbles are heard in various directions, if we are to believe the statements made in the official organ of the telegraph staff. Many of the complaints are obviously absolutely without foundation. The authorities, who very properly insist that the condition under which the additional increments are to be given shall be a real possession of technical knowledge, require the applicants to produce elementary certificates from the City and Guilds and Science and Art Departments (the certificates not dating back more than five years), or, in the absence of these to pass an equivalent Departmental examination. Such conditions can certainly not be considered to err on the side of severity, especially in view of the fact that the reward is an addition to the yearly salary, and not simply a £3 or £5 prize, which is the coveted desire of those who enter for the City and Guilds examinations. All sorts of threats are made that the matter will be brought before Parliament, which will doubtless be asked to sanction the double increment being granted without any examination at all. But, seriously speaking, the general action of the telegraphists, although it may be justified to some extent, is, if the true facts were known, much more likely to excite public indignation than sympathy.

In connection with the engineering work of the Department, the construction of the underground line with paper insulation between London and Birmingham will be watched with interest. The experiment (if it may be called such) is a bold one, but may have important results.

An interesting experiment in connection with the conveyance of mails is the employment of steam, oil, and electrical vans for the purpose; the experiments so far appear to have been quite satisfactory.

COST OF CURRENT FOR TRACTION.

Our contemporary, the *Railway World*, is to be complimented on its last issue, not only for its excellent appearance, but also on account of the contents, which include a well illustrated and very full description of the Clontarf Electric Tramway, and a valuable and well-timed article upon "Tramway Power from Lighting Stations: What is a Fair Price to Charge?"

Some criticism of the latter will be opportune at the present time, and we hope may be appreciated by our readers, seeing that the subject is one of increasing interest all over the country.

After stating the general position—the whole matter being, of course, simply one of bargaining, of buying and selling—the local authorities or lighting companies naturally desiring to obtain the highest possible price per unit, whilst the tramway companies are correspondingly anxious to pay no more than current would cost if they generated it themselves—our contemporary proceeds to state the case for each side, afterwards summing up with a strong tendency on the whole to a verdict for the tramway companies.

The objection may be raised that this is no more than might be expected from a traction journal, but it falls within our province to pose as a disinterested judge in the matter; and we certainly think that no judicial summary and comment upon evidence could be clearer or more fair.

As a mere matter of chronicling figures, our contemporary first of all gives costs of producing current per unit sold in different places, which may be tabulated somewhat as follows:—

I.—*Local Authorities*—

	No.		Average cost (pence).
(*a*) Selling over 1,000,000 units per annum	4	...	1·63
(*b*) Selling from 500,000 to 1,000,000 units per annum	4	...	1·95
(*c*) Selling less than 200,000 units per annum	20	...	3·51

II.—*Companies*—

	No.		Average cost (pence).
(*a*) Selling over 1,000,000 units per annum	1	...	2·44
(*b*) Selling between 500,000 and 1,000,000 units per annum ...	3	...	2·28
(*c*) Selling less than 200,000 units per annum	12	...	4·26

Following on this we have a long statement from the manager of a large electric lighting company, whom we have not much difficulty in identifying, and who, even apart from that, might readily be put down as being engaged in negotiations for the sale of current to one or more tramways, and, therefore, particularly anxious to keep up the price. His reasoning is clever, but we think also very superficial and hardly fair, as he appears to choose out for emphasis the conditions or factors that favour his own side, without allowance for those that tell against him. Perhaps one can hardly expect impartial judgment from those vitally concerned in maintaining high prices, yet we cannot too strongly urge upon the electric lighting interests that they should give all possible assistance to electric traction, inasmuch as they should have everything to gain and nothing to lose by its introduction. To choke off by prohibitive tariffs any efforts to instal electric tramways, will, to our mind, resemble the killing of the goose that lays the golden egg.

The electric lighting manager alluded to is made to say that with a tramway plant the load factor in proportion to the total capacity is, as a rule, not more than 50 per cent., whilst in a lighting station, taking load to *plant capacity running* it is not impossible nor even uncommon to get 80 per cent. utilised. Allowing a reserve of half the plant for a tramway station (though we don't see why any greater reserve is necessary there than in a lighting station) he considers that the load factor on the whole machinery in working order may for tramway work be as low as 25 per cent.

Even assuming that these figures are correct, it is decidedly one-sided to bring them forward in this way without, at least, some mention of the time element. We have always understood that the term "load factor" implied the ratio of average output to maximum output spread over the whole day of 24 hours; but, apparently, the expression has also a more limited meaning than this. The comparison would surely be in any case more fairly stated by saying that, with a lighting station, an average load factor of 80 per cent. may be realised for a few hours only per day, whilst in a tramway power house the load factor, even presuming that it is no more than 50 per cent., at any rate implies a steady consumption of current for 12 or 16 hours a day. It is, we need hardly point out, more economical, as a rule, to run 16 hours a day, even at half load, than for three or four hours only at three-quarter load, so far as wear and tear of plant is concerned, as well as general working expenses.

The net advantage is really, in this respect, most emphatically on the side of traction plants, as the *Railway World* article points out in stating the case for the tramway companies through the mouth of a prominent traction company, that may also be recognised without much trouble. The Wright system of charging at Brighton for electric supply is very suitably brought forward to prove the statement that electric tramways are exceptionally good customers for current, requiring from half to two-thirds full load for perhaps 16 hours a day. Thus the cost per unit, at 7d. for the first hour, and 1½d. for subsequent hours, works out to not more than 1·8d. per unit for the whole 16 hours.

Moreover, the further point is made that for traction work the supply of current paid for is measured *at the station*, and therefore should not be subject to any allowance in cost for losses in distribution. The percentage of current sold to that generated appears to average about 75 to 80, so that a considerable allowance ought to be made in this respect, if the tramway company is to bear distribution losses.

Winding up the discussion, our contemporary expresses a belief that we have not yet seen the end of possible economies in the production of electricity on a large scale, spread over the greater part of the day; and it instances some examples from America where the cost of power varies from a little over ¼d. to ½d. per car mile, including fuel and supplies, labour and repairs.

We are thoroughly in accord with our contemporary in considering such tariffs as 3d. and 4d. per car mile or per unit for tramway current to be simply prohibitive under average conditions; the maximum rate fairly chargeable ought not, so far as we can at present say, to exceed 2d. in view of the long hours of demand coupled with steady use of current. The momentary variations from zero to maximum which are sometimes characteristic of a line with sparse traffic doubtless affect the instantaneous governing powers of the engines, but can hardly be said to make much difference to the steady jog-trot of the recording watt-meter that helps to draw up the bill for current delivered. Nor should they necessarily imply the provision of expensive duplicate plant with greater capital outlay and consequent higher cost, in so far as that is concerned, of current delivered.

THE NORTHERN SOCIETY OF ELECTRICAL ENGINEERS.

(*Annual General Meeting, January 10th, 1898.*)

ABSTRACT OF PRESIDENTIAL ADDRESS

By Mr. John S. Raworth, M.Inst.C.E., Member of the Institution of Electrical Engineers.

Gentlemen,—My first impulse is to acknowledge with my best thanks the spontaneous and almost embarrassingly sudden invitation to accept the presidency of this Society, which your good nature has forced upon me.

As at the time of its receipt I was not even a member of Council, I had no expectation of receiving such an honour; nor am I yet satisfied, knowing as I do from my experience on the Council of the Institution of Electrical Engineers, how onerous are the duties of a president, that I shall be able to fulfil them to your satisfaction.

The war of the future will be an industrial war, in which the resource and dogged perseverance of the English race will be as much in request as they were at Waterloo. We are up to our ankles in it already, and yet our engineers, the advanced guard of our industrial forces, having heard so much about the might, majesty, and magnificence of the British Empire, have thought it a small matter to desert the trenches for six months, vainly to discuss the breadth of the proposition contained in the declaration of the Centurion of old: "I say to this man 'go,' and he goeth, and to another 'come,' and he cometh, and to my servant 'do this,' and he doeth it."

But, gentlemen, *we* know that the muscle and sinew of the engineering trade is true at heart; we know that we have the right stuff at our backs, and that when the specious agitator shall have descended to his proper place, and when danger shall have become apparent even to those who do not sit in the conning tower, then there will be no desertion, then every man will do his duty, and none will dare to speak to the man at the wheel.

The history of electrical engineering, apart from telegraphy, is so short that we have probably no member who does not carry the whole of it in his memory; it is, therefore, quite unnecessary for me to break out into reminiscences. I cannot, however, refrain from reminding you that when I started electrical engineering in Manchester 20 years ago, there existed in Mill Street, Ancoats, a factory devoted entirely to the production of dynamos, arc lamps, and projectors; we have every reason to be proud of our townsman, Mr. Henry Wilde, whose fame, though world-wide, is surpassed by his modesty; and it must be a source of satisfaction to every member of this society to know that Mr. Wilde's genius and foresight brought him a substantial fortune.

After the era of Mr. Wilde's activity, Manchester in matters electric moved but slowly; now, however, under the inspiring influence of Mr. Alderman Higginbottom's faith and fervour, it is rising to an appreciation of its possibilities, and in all probability will very soon again set the pace for the rest of the world.

The one thing we want is faith—it is quite as important in mechanics as in religion: for as by faith the walls of Jericho fell down, so will the walls of prejudice and incredulity, which at present bar your path to the promised land of fame and fortune, collapse at the first brush with the dynamics of faith.

The time for hesitation and half-heartedness is past, money is plentiful, and the investor has full confidence in "Electrics." I propose, therefore, to look ahead a little, in the hope that I may at least succeed in stimulating you to apply your minds most seriously to the problem that lies before us.

The problem is: How can we possibly supply the demand that is about to break upon us?

When we entered upon this business we had practically only one commercial outlet—viz., lighting—and we were unable by any amount of sophistry to make the public believe that electric light was cheaper than gas; now the conditions are changed, and Mr. Arthur Wright informs me that in Brighton the working-man and the fried-fish shop are his best customers. He is actually realising Mr. Preece's oft-derided statement, that the electric light is the poor man's light.

I beg you to think what the result will be so soon as the great British public shall awaken to the fact that electricity, with its enormous advantages, can be bought for actually less money than its equivalent in gas; and it may awake any moment; probably your next president may be in the happy position of having to congratulate you thereon.

I said, a moment ago, that when we entered upon this business we had practically only one commercial outlet; even to-day that same outlet is our mainstay, but other developments are growing so rapidly that one finds it impossible to keep pace with them; take, for instance, electro-chemistry; old in conception, new in economic application.

This great work has begun: who can tell when it will end, or what demand it will make on our national capacity of production?

Again the melting and welding processes are being gradually introduced into engineering workshops; intrinsically expensive, they justify their existence by electrifying into life most costly corpses—an almost infinitesimal deficiency is made good, a blow-hole is filled, a crack is welded up, hundreds of pounds are saved by the expenditure of a few shillings. At present none but the enlightened use this process, but it is only a matter of two or three years before every engineering establishment in Great Britain shall be so provided.

I have now to call your attention to the subject of locomotion, and in so doing I do not intend to discuss the question of electrical transmission of power for main lines of railways. I leave that to my successors. I would rather direct your thoughts to the more pressing question of tramways and light railways. Hitherto, we have done next to nothing, and the small experiments which have been undertaken have been carried out almost entirely with American machinery. Even under these conditions the results have been satisfactory. We must not, however, lose sight of the fact that we possess several home-made electric tramways, including Mr. Holroyd Smith's Blackpool line, which, although constructed 12 years ago in the face of difficulties not encountered in the case of any other electrical tramway in England, has nevertheless given satisfaction and paid its shareholders. We have also the Liverpool Overhead Railway, the Isle of Man tramways, and the South Staffordshire lines, as standing proofs of our native ability to deal with problems of the most varied and exacting character.

The total mileage of electrically-worked tramways in Great Britain is now 93. The projected lines, however, amount to no less than 340 miles in length, and the capital required for their equipment will certainly not be less than £3,000,000.

But even this large amount of prospective business represents only the beginning of the demand. Very soon horse traction will be superseded by electricity on the whole 1,000 miles of tramway now existing; and in addition to this, London will be honeycombed with subterranean electric railways, and provincial towns will adopt systems of surface tramways far more elaborate and extensive than those which now exist, even if they have to widen their streets to accommodate them.

There is already sufficient indication of what is coming in the attitude of Manchester, Leeds, Sheffield, and Glasgow. The fact is, that electric trams pay both the owner and the user; wherever they run no one can afford to walk, except for exercise, for the saving of time is enormous. Even in England, where the eight miles an hour rule is in force, there does not appear to be any difficulty in getting over the ground. I cannot explain this in detail; you must see it for yourselves.

What we want is to get rid of the horse in cities. He is all right in the country, but in town he is a nuisance. Consider, for one moment, what we could do if he were kept outside. Firstly, we should make our streets of hard asphalte, as smooth as a billiard table; secondly, we should keep them quite clean; thirdly, our electric motor carriages would run with so little friction, that even our present batteries would fulfil all the conditions.

The only difficulty arises out of the time necessary for making the change; if it could be made in a night, then Manchester might start on the new system to-morrow, and even Alderman Higginbottom would not recognise his native city, so delightful would it appear. But although it cannot be done in a night it will be done by a long and painful process, in which the electrical engineer will have to overcome the obstruction of bad roads and supplant the horse on his own ground; then, ultimately, the civil authorities will alter their roads to suit the new conditions.

What a pity it is that we electrical people cannot start afresh, and build a new city, embodying all the latest improvements.

I fear our electric city is a long way off, so in the meantime we must make the best of those we have, and no one will deny that there is room for improvement.

In the first place, we must abolish smoke.

Which idea brings me at one step right into the middle of a subject—the most pressing and important subject with which it is possible to engage the attention of a Lancashire audience. I refer to the driving of machinery for manufacturing purposes by electrical distribution of power, including the total abolition of line shafts, counter shafts, wheels, ropes, pulleys, and belts.

The day for tinkering with this problem is over; every man in this room knows that it can be carried through with absolute certainty, with satisfaction to the manufacturer, and with an enormous saving both to himself and the community. But the manufacturer does not yet know that the shaft of his machine can be fitted with a three-phase motor without commutator or brushes, and less complicated than his present double pulley and strap fork. When you have succeeded in impressing him with this fact, the remainder of your task will be an easy matter, but it must be undertaken methodically. The first step is to appoint a commission to settle uniform periodicity and voltage; the second is to equip an electrical manufactory capable of turning out 500 cheap motors per week; the third is for machine makers to attach the motor in place of their present pulleys, so that when a manufacturer buys a machine, he buys it all ready for attachment to his power circuit.

Having reached this point, it is obvious that the manufacturer will no longer desire to buy coal; he will be quite satisfied with watts, which may be produced at the pit's mouth, and sold retail for less than they can now be supplied mechanically to the machine axis.

The whole question of external supply of power turns on this question of economics, and your manufacturer's eyes will gleam with rapture if you can prove that you can save him a thousand a year.

Happily your task is an easy one so far as argument is concerned, and if illustration be required, I am not sure that we members of this Society could spend our savings to better advantage than by taking a representative deputation of Lancashire and Yorkshire manufacturers through Switzerland and Germany, to show them how the old order is giving place to the new; how the millwright is disappearing in favour of the electrician; how 25,000 mechanics are struggling to keep pace with the demand for electrical machinery, of which about three-fourths is required for power purposes.

Some of it, of course, is for the transmission of water-power; but even in Switzerland water-power is seldom so well placed that it can produce electrical horse-power cheaper than we can produce it by steam at the pit's mouth; that is to say, at about £4 per annum—constant service, or £38 for factory hours.

When we consider that the present cost of steam power for a cotton mill is about £3 per annum per indicated horse-power, and that the electrical horse-power required in its stead would not be more than 65 per cent., you can easily see what a large margin there is for profit to the producer and for saving to the consumer; for it must be remembered that the load curve would be practically a parallelogram, or rather two parallelograms, one for the day and a smaller one for the night.

But, gentlemen, great as would be the saving to the spinner, and the large manufacturer whose steam power costs him £3 per horse-power, it would be vastly greater to those thousands who employ small steam engines which run up the cost of power to £10 or £12 per annum. The aggregate annual saving to Manchester and Salford alone would be immense, quite beyond my power of calculation; but you must not suppose that because our imagination fails to grasp the figures involved, that the change which is coming will be long delayed on that account. Some friends of mine who have lately visited the Continent of Europe report as follows:—"Evidence was afforded us that not only are new factories all over the Continent laying down electric power throughout, but that works already equipped with steam power are pulling it out and substituting electric."

In America the same process is going on, so it follows as a matter of course that we must either quicken our pace or drop out of the running altogether.

Happily the coal pits around Manchester are so close to the city that there will be no new difficulties in transmission, and a very moderate voltage will suffice.

It is obviously outside our province to discuss the various possible methods for raising the capital. My own impression is, that when the profitable nature of the investment comes to be understood, there will be no difficulty in raising a million to put down a pioneer plant of 50,000 horse-power, with an earning capacity of close on £200,000 per annum.

Gentlemen, when I look round this room and appreciate the fact that you are the men who must carry out all these great works, then I understand the honour that is placed upon me in being called to be your president; then I feel thankful that you are all young and eager for work—there is plenty of it waiting for you—but I am not so pleased that we are few in number, for it is not possible to manufacture an electrical engineer either in five minutes or five years, so in the very nature of things our ranks will swell but slowly.

Many of you doubtless wonder, and wonder in sorrow, why our progress in this country has been so slow compared with the rapid strides which have been made on the Continent. I have seen and heard many explanations, all partially true, but the real and predominating reason is the low price of gas in this country, whereas on the Continent gas is usually so high in price that the investor did not feel any hesitation in backing electric light to beat it. Consequently, supply works and manufacturing works were developed at a great rate, and are still increasing in size and output at a speed which would frighten us in this country; and yet I have no hesitation in saying that if all our makers of dynamo-electric machinery were forthwith to proceed to double their capacity, they would not be in time to cope with the demand which will come upon them.

I have indicated to you several sources, of which three are principal ones, from any one of which sufficient demand may arise to swamp all our works; I say may arise, but the whole three may with almost equal probability be tapped at the same time, and then where shall we be? Already large quantities of machinery are being imported from the Continent and from America, simply because we are not prepared to make them here, and yet the blind leaders of the blind think this a fit time to restrict the output of our machinery. It is like shutting up the gun factories in the middle of a war. Our only hope is that the six months' discipline may atone for the six months' loss.

This brings me to the consideration of a subject which, though not strictly electrical, is nevertheless very intimately bound up with our lives and fortunes: I refer to the steam engine.

Our electrical brethren in Switzerland and in some parts of America can get along well enough without the steam engine, but it is not so with us. It is fortunate, therefore, that we have plenty of coal with which to feed him. But this abundance of coal has tended to make us less careful of it than our less fortunate neighbours. The result is, that although we make good steam engines, in spite of American comments to the contrary, we have not made economy our first consideration; we have, moreover, been confirmed in this practice by the belief that economy of coal could only be obtained by increased capital expenditure and troublesome complications. But that view is totally and fundamentally erroneous. I have already proved in my paper on the generation of electrical energy for tramways, read before the Institution of Electrical Engineers in 1897, that a high mean pressure is not uneconomical per electrical horse-power; and consequently that the gain by using large engines with very early cut-off is only apparent when the indicated horse-power is taken as the basis of comparison; further, I can give you this solid fact: that the large engines at the Wandsworth electricity station are producing an electrical horse-power at practically the same steam consumption at full load as at half load, thus showing that, taking all the losses into account, the saving effected by extreme expansion is cancelled out.

Therefore we arrive at this fact, that existing engines might easily drive more spindles without increasing the cost per spindle, although there would be an increased cost per indicated horse-power. This seeming paradox will not cause you any trouble, though it may puzzle the cotton-spinner. But, gentlemen, our friends on the Continent have gone a step further: they have improved their engine and improved their steam by superheating to such an extent, that I have actually seen a 500-horse-power engine, driving an average of 300 horse-power, fed by a single-flued boiler 5 ft. 9 in. diameter by 26 ft. long. This impressed me more than the professorial tests, which gave 8·8 lbs. of steam per indicated horse-power. To the saving in coal we must add the saving in boilers and other subsidiary apparatus.

My firm belief is that the economy now being realised in Germany by Wilhelm Schmidt and Company is obtained at a lower capital cost, and with less complication, than we find with our Lancashire engines.

Gentlemen, you are fully aware by bitter experience that the demand for steam engines in this country altogether exceeds the supply, and that in consequence of this state of affairs engines are being introduced from America, which, although well built, will not comply with English specifications as to economy; and consequently we are in the position that, however we may exert ourselves to fill the coming demand for electrical plant, we shall be either without the means of driving it, or dependent on American engineers for our steam engines.

This is not a delightful prospect, but we must face it, even if it be to the tune of two or three millions of additional capital in engineering works.

Gentlemen,—The keynote of the few words which I have had the honour of addressing to you this evening is *faith*—faith in yourselves, faith in electricity, faith in the new dispensation which is dawning on the world.

Your faith will be faith founded on knowledge; and exactly in proportion as you turn it to account by making preparation to gather in the harvest ripening under your eyes, so will be your share of the fruit. You must copy the example of the capitalist and financier, and obtain some monetary interest in every good scheme you may be connected with.

There remains for me nothing but to congratulate you on the fact that, after years of hard work, quite inadequately remunerated, the goal of your ambition is glittering before you. In a few months you will be in the position of our forefathers, the mechanical engineers, who reaped their reward almost before they had earned it. It behoves you, then, to be ready, be constantly on the watch for the little cloud no bigger than a man's hand, and wait not for the prophet to say to you: "Prepare thy chariot and get thee down, that the rain stop thee not."

ENGINEERS' STRIKE.

The present appearance of this quarrel now is that the employers are extending the area of lock-out and throwing more men upon the funds of the unions, and pressure is being brought to bear upon foremen to abandon their connection with the unions as being altogether opposed to honest service of their employers. We have all along set ourselves against any attempt at "smashing of the unions," but we are bound to say that our sympathies with trades unionism are very quickly evaporating in face of the exceedingly foolish action of the men in prolonging the dispute at the bidding of their executive in face of every just and reasonable consideration. We have upheld trades unionism, not because we have thought the men required it from want of intelligence, but because we have looked on the working man as a person as being often unable to look after his financial interests as he should do. We are more than ever convinced that he is incapable of doing so, but we are equally convinced that his employers would far better be trusted to do this for him than those who have taken the work in hand, and, in doing it, have landed the men in their present dilemma. As regards the modern form of trades unionism, we honestly believe it better that there should be no trades unionism at all than the modern form of it should any longer continue to work its wicked ways. To judge by the letters which pour into the daily press, the public are beginning to see the truth of the matter. A correspondent of the *Standard* points out that this six month's strike has put a stop on the cry of a "living wage" so much heard lately, for men have clearly demonstrated that a mere fraction of their regular wages has proved quite enough to live upon. The same correspondent points out that even when the strike is over there will be, for a long time, a heavy drain on the union funds as so many men will be unable to find work at first. He has also discovered the fact that for every hundred pounds of profit lost by the masters the men are losing five hundred pounds. Mr. T. A. Brassey writes to the *Times* suggesting that a shorter day and two shifts would probably be as productive of work as a nine hours' day on the present three shifts per day. We find that men are very averse to a two shift day. They talk about their working men's railway ticket and do so much grumbling that where the idea has been suggested it has not been carried out. But one of the best letters of the week is that of Mr. W. McDermott to last Friday's *Times*. Like ourselves, he thinks there is too much tenderness with the trades union idea. The trades union are trying their best to smash the Employers' Federation. Why has not the Federation an equal right to smash the union? The Federation does not wish to do so, but Mr. McDermott is perfectly correct when he states that the benefits which have arisen from trades unionism have been much overrated. The working men have not, he considers, benefitted by them. Wages have gone up because, formerly, British trade was ahead in every manner of mechanical appliances, and trades unionists benefitted with every one else. But now that other nations are using all the machinery possible, and English trades unionism is doing all it can to oppose machinery, it is certain that high wages can no longer be possible. It is, says Mr. McDermott, merely a coincidence that the results of machine using have been contemporary with the action of trades unionism, and the benefits credited to the latter are really due to the former. In restricting output, the men's leaders are, at any rate, striking at the root of all past success, however derived. If the men's leaders be truthful when they deny that their policy has been to restrict output, then must it be that the workmen have themselves deteriorated. They can no longer be considered fit competitors of Americans, Frenchmen, or Germans, and the sooner capital avoids the engineering trades the better will it be for capital. But Mr. McDermott only advances this contention to support the fact that it is the men's leaders who are responsible for all the mischief. He states that an English company owning works in Chicago and in England have of course to pay American workmen about third more than they pay in England to cover the difference of living. Yet the labour cost on the production of the English shop is higher than it is in America. This is not a question of race for the American workmen are largely Englishmen, who work as hard over there as Americans. They are simply freed from the paralysing influences of trades union leaders, few of whom ever did a decent day's work in their lives. The result as far as McDermott's Company is concerned is, just that the work is being done in Chicago, carried 900 miles to New York, and then to London, whence it is often sent abroad. This is simply taking work out of the country. Now, if the men who have been idle for six months, and have had the use of all the papers in the public free libraries and could have read up all that has been written in the time, and do not yet see the facts of the case, they must be blind and unthinking beings, incapable of taking their proper place in the world, and fitting dupes of their leaders. Like ourselves, Mr. McDermott does not think so much of the hours question. It is the personal matter which frets his soul, the idling, the dishonest acceptance of wages for work slovenly or half done, the mean and spiteful treatment of their non-union fellows, and their general ignorance of the plainest facts. There were reports spread a few days ago as to secessions from the Federation, but they were denied by Col. Dyer, and the only foundation from which they could have arisen seems to have been the action of one or two firms in offering to re-open on the terms agreed to at the Conference, but without success. A Carlisle firm tried it, and obtained one or two men, who left through picketing. The *Daily Chronicle* which has throughout the strike manifested a singular ignorance of facts, has made all possible out of the above, and also out of the case of Messrs. Fowler, of Leeds, who are said to have tried to come to terms with the allied trades, though members of the Federation. In the meantime another large firm in Leeds joined the Federation, and more lock-out notices have been posted in Nottingham and Preston. Sir Benjamin Dobson, at Bolton, reported the Federation solid as ever, or more so. The Bishop of Norwich rather shines out above the ruck when he states that the employers ought to be considered in their contention that trade cannot be continued if the men's demands are conceded. He falls back on prayer, but we sadly fear he knows not the British workmen. They believe not Moses nor the Prophets, though the country is overrun with foreign machinery.

The *Telegraph* is responsible for the statement that some of the strike leaders have become alive to the fact that the public are not with them. It has taken them a long time to find this out, and it will, perhaps, take them as long to realise that the public have also begun to learn that the income of the engineers on strike was much above that of the public, which is expected to subscribe. The people called on to subscribe are those who work up to 16 hours a day, are often poor clerks who have no voice in the conduct of business which they are really in a better position to understand than is a working man to meddle in shop management, and the thousand and one men in the street who don't get paid for overtime. The men's leaders are slow of thought and yet they are reported as doubting whether the

3d. levy proposed at the Memorial Hall conference will be raised. They are now hoping to drag on the strike until Parliament opens, as though Parliament—that refuge of those destitute of self help—could make a losing trade pay a fixed wage. The men have the whole business in their own hands if they would use their plain senses to see it. They have only to do a fair day's work to make engineering so busy in England that the wages of the good men would go up considerably, and employers would be well able to afford it.

If our good bishops and dons really feel an interest in the subject of the strike, why do they not join hands and employ a reputable firm of chartered accountants to examine the books of a few firms and see for themselves the proofs that apprentices and labourers are easily outworking the supposed skilled unionists? They could do this. We feel sure the books of several firms could be opened to them under the published headings of a letter, as *a*, *b*, *c*, &c. There would be some sense in this. If, having found out the truth for themselves, they then elected to pray for the conversion to a right frame of mind of the men or the masters, whichever they found to be wrong, their prayers might avail much, but, to leave it all to Heaven, savours too much of faith without works, which we all know to be very dead. Six months has shown the employers that they can do without the A.S.E., and in support of this it is pointed out that iron keeps its price and must be going into consumption. The Free Labour Association has alone supplied 24,000 men to different employers. No employer seems to be reducing wages, but all are going on in a way that ought to be very satisfactory to any real honest trades union. The fact seems every day more apparent that the men on strike are pursuing a chimera. They are standing idle on the shore and watching the tide of industry sweep past them, and on the shore they will have to remain. We cannot but help being glad that in every nation there are certain disadvantages which help to counterweigh the advantages. Were England alone in this we should speedily be ousted from the World's markets. The *Engineer* has pointed out how in America, where they are steeped to the lips in that most ignorant of superstitions—a protective policy, they have free trade in labour, and labour does very well unless upset by tariff mongering. In England we have free trade and do very well, but to the American we appear to be an ignorant and stupid set of worn out fossilised conservatives because we have not got free trade in labour. If we had free trade in both items we need not fear America. Englishmen are as inventive and as capable as any American, but of what use is it inventing a 50 per cent. better machine to be butchered by a stupid trades unionist.

Speaking at Edmonton on Sunday, Mr. Barnes had something to say about the aim of toilers to secure a more equitable distribution of the world's good than hitherto. He seems to go a curious way to attain this—putting his members on starvation diet for six months and compelling them to accept nothing of the world's good except as paupers. Then he talked about American workmen being paid more hour for hour than English workmen. This is not true in spirit. English workmen are paid hour for hour more than Americans if the purchasing value of money be taken into account. But, apart from this consideration, and in mere coin by weight, Americans are not paid one-half—often not one-tenth—of what Englishmen are paid for the same amount of work done. Further, if English workmen would do as Americans do, and would help machinery and not hinder it, their financial position would be better in every way than that of the American. Again, one stands aghast at the impudence of a man who can bring forward American workmen as a comparison when the relative attitudes to machinery are considered. However, enough of Mr. Barnes's tergiversations. A crushing reply to anything that can be truthfully advanced by the trades union is to hand in extracts from the shorthand reports of the Conference, from which it is plainly to be seen that everything was agreed to at the Conference except the change of hours. It is a good thing these notes have been published, as they will assist to prevent the public from being led away by misstatements. The reported defection of Messrs. Fowler, of Leeds, from the Federation has been shown to be false. The men themselves asked the firm to meet them for a friendly conference. Perhaps the men are a bit tired of Barnes. Mr. Fowler has stated that there is no thought of making any compromise.

There are now nearly 700 firms in the Federation, and some 60 or 70 fresh lock-out notices have been posted since the Conference concluded. We observe that Mr. Barnes has a complaint about the age of workmen being on an average under 40. We do not believe Mr. Barnes, so far, at least, as the engineering trades are concerned. He calls it murder, and so on. We suppose he is referring to long hours. He refers then to those "splendid fellows in Germany" who have been sending more money. Those splendid fellows have to work a good deal longer hours than Barnes' dying lambs, who do not die of too much work, nor do they die from too little to drink. *Verbum sap.*

Mr. Yarrow is returning from America. He has been studying American methods, and he says of the workmen, "They take a greater interest in their output.

"Each man tries to do all he can, in marked contrast to the English system.

"I am surprised at the management of automatic machinery in American engineering works.

"One man here has charge of several machines; in England this is against the union rules, consequently a mechanic is idle a considerable part of his time.

"The lower prices of raw material in the United States," continued Mr. Yarrow, "have put American engineers in direct competition with English, and I believe that competition will continue to grow keener.

"Materials for the great Central Railway of London are being supplied by Americans, who are shipping steel billets to England, boiler plates to Holland, and deck beams to Belgium, which English firms formerly supplied."

It is reported that the number of men applying for reinstatement at Messrs. Denny & Co., of Dumbarton, is becoming greater.

Several employers have given written engagements to their men who have stood by them during the strike, so that their services must be retained after the strike. The Federation have issued a poster containing their conditions. We can only say that, terms or no terms, collective bargaining or not, there has got to be a change in England, and we believe it will come in the way of more honest work, and that England will not go out of business, as she certainly must do, if trades unionism be allowed any longer to work ruin, and encourage rank robbery and idleness.

CORRESPONDENCE.

Tests for Faults in Submarine Cables.

I have read with much interest a letter from Mr. W. J. Murphy, of the c.s. *Amber*, which appeared in the columns of a contemporary of the 31st ult., wherein he comments on several points in Mr. Schaefer's test—entitled "A New Method of Localising Total Breaks in Submarine Cables"—which appeared in the same journal under date October 15th, 1897. Any new method or improvement on those already known for localising faults is naturally of so great interest to all, and more especially sea-going electricians, that I have ventured to make a few remarks on the subjects mentioned in Mr. Murphy's letter.

I cannot wholly endorse Mr. Murphy's statement that "it would be rather misleading, in my opinion, to give quantitative comparison of the results by different methods of tests taken for the localisation of the same fault or break." For example, in the case of fractured conductors, there are a number of similar tests which one can apply with perfect confidence in the results, and I know of no better criterion of the merits, or otherwise, of a new test, which claims to have advantages over another—both being designed for the same character of faults—than to compare results obtained on the same fault taken under the conditions stipulated by the authors. It is simply a question of proving the test before adopting it. Under these circumstances, I consider it would be quite correct to draw comparisons between the following tests, say—Kennelly's two methods; Schaefer's, Rymer-Jones's and Cann's modification of Kennelly's, and any such tests which are practically based on Kennelly's. These being taken from one end only, *i.e.*, in the case mentioned of a fractured conductor, the personal equation of an assistant does not enter. We can, therefore, classify the above-mentioned methods under one heading, as being applicable to the same character of faults.

On the other hand, when dealing with partial earth faults of high resistance—the conductor being continuous—which necessitate tests being taken from both ends, I am quite in accord with Mr. Murphy when he remarks "that special considerations such as the faults distance, strength and variability of the electric current, condition of cable, apparatus available, the personal equation of the man at the other end, &c., renders one test in particular preferable." That *one* test cannot of course be particularised, because this again becomes a matter of individual opinion. In partial earth faults, and more especially when the fault resistance is high and variable, the personal equation of the assistant at the distant station becomes a factor of the highest importance, and when his electrical knowledge is slight, or, to say the least, very elementary, the results obtained from his end will not as a rule be very reliable, and, therefore, the lot of the electrician responsible for the localisation is not a happy one. In such a case where no skilled assistant is available, it would be far better to use the most simple tests applicable—having regard to the character of the fault—and which would give a near approximation of the distance, than to employ another method necessitating more knowledge of electrical connections, &c., and greater exactitude in key manipulation and reading—which, with skilled assistance, might rightly be considered to give more accurate results—but with only unskilled co-operation might only lead to hopeless confusion, loss of time, and, at the best, unreliable figures.

Again, in cases where the testing current is limited by the company's rule to a certain maximum voltage—owing to the general weakness of an old cable—this is greatly against some tests, and very often practically excludes their use.

With regard to the relative merits of *false* and *scale* zero tests, my experience generally has been when localising faults by the Kennelly methods that there existed but little difference in the results—if any—when employing the two tests as a check against each other on the same fault. It is in balancing to false zero that the personal equation enters more largely than in scale zero testing, especially when the fault resistance is high and changing rapidly under the action of the testing battery. Each method has its own particular merits, under certain conditions, but the scale zero method is undoubtedly the test, *par excellence*, for repairing ships, if only for one reason—though, of course, possessing other advantages—that the practical execution of the test occupies about one-third, or even less time, than when balancing to false zero, very often a matter of vital moment when the ship is hanging on to the cable, and every minute is of grave importance.

With reference to another point, "the application by Mr. Schaefer of the scale zero method to break testing is a special case, because by its use the difficulties introduced by polarisation and capacity are overcome, &c." These difficulties have already been overcome by Kennelly's tests. Again, I fail to see the soundness of Mr. Schaefer's "earth current" correction; it appears to be unreliable in principle, and not to be depended upon for many earth faults, especially those having, comparatively speaking, high and variable resistance, and with polarisation changes occurring rapidly. With a large surface exposure fault, the cable current being also steady, the results obtained may work out approximately correct. More information on the subject of this test would be useful.

As I have already trespassed too much on your valuable space, I feel I must not enlarge on any more points, but will simply remark, in conclusion, that I trust Mr. Murphy will ere long give the profession an account of the new method of locating high resistance faults which he speaks of in concluding his letter. With his varied experience of fault testing, the subject matter cannot fail to be both instructive and interesting.

Herbert E. Cann.

January 7th, 1898.

A Defence of Germany.

When next Herr R. Von Fischer-Treuenfeld takes upon himself to write in the strain of his effusion of December 28th ult., which appears in your issue of the 7th inst., perhaps he will endeavour to make himself acquainted with facts. It is all very well to speak of the German Emperor as the head of a friendly nation, but it is well known that his animosity against this country is intense, and that at the time of the Transvaal trouble he did his best—or worst—to injure England, and for years the whole press of Germany —under the surveillance of the State—for press freedom is hardly existent in Germany, has teemed with abuse of ourselves, and wild statements as to destroying England's power and commerce. Englishmen have no jealousy of fairly conducted trade rivalry; but attempted highway robbery is not commerce. Further, at the time of the Emperor-Kruger flirtation, Germans resident in Great Britain, making their living here out of our British tolerance and justice to all foreigners, made no secret of their desire to help Germany against the land which sheltered them. Your correspondent tries to make a point of Dr. Ludwig Mond's present of £100,000 to the Davy-Faraday Laboratory. Well, what of that? Did not Dr. Mond make this money, and a good many other hundred thousands, not to say millions, at Northwich in Cheshire?

Herr Treuenfeld talks of war between England and Germany as though England had fomented it, when he must know the present bad feeling has arisen entirely since his Emperor's telegram.

If Germany's Colonial expansion is to consist in grabbing England's colonies and inciting rebellion in States under England's suzerainty, the sooner we get to war the better. But we hope all Germans are not of your correspondent's persuasion, and still have some ideas of common honesty remaining. Let Germany mind her own business and leave ours alone, and let German residents in England have the decency to be loyal to the land which gives them food and shelter. So far, they have not been so. Germans are naturally a quarrelsome people; hence the 30 years' war of which Herr Treuenfeld speaks, caused, I believe, by too much fussing about this king and the other. And now that the present German Emperor makes it the first object of his life to injure England, we have Herr Treuenfeld worrying his little self because he is treated to a little ridicule by the people whose throats he is so anxious to cut.

W. H. Booth.

London, *January 8th*, 1898.

Mr. R. von Fischer-Treuenfeld protests too much; he may be more briefly answered. He has two grievances (1) our criticisms of the German Emperor; (2) the causes which lead to these "rhapsodical recitations."

With regard to the first of these, it may at once be said that if Our Gracious Queen were to make herself as absurb as her grandson sometimes does, the refined German press would be the first to point it out. Presumably Mr. R. von Fischer-Treuenfeld hesitates to show his own sense of the Imperial humour from a wholesome fear of prosecution for *lèse-majesté*—or dare we suggest that he is a convert to the New Evangelism (for ever and ever)?

As regards the second, the English do not expect a monopoly of the world's trade, nor do we begrudge Germany a commercial success. But we *do* object to English marks being put on German goods, and as all our ports and colonies have always been thrown open to German subjects and commerce on equal terms with our own, after we have prepared the way with our blood and our money, we most strongly resent the ingratitude and impudence with which the Germans continually treat us.

Mr. R. von Fischer-Treuenfeld cites emigration figures; does he take into account the great and frequent additions which have been made to the German army of late years? He talks of colonies; does he seriously suppose that German emigrants would not rather stop in the Fatherland than go to German colonies? Will he tell us that there is more money per head of population in Germany than in England? Does he not know that those who emigrate from England are largely composed of the dregs of other countries? Finally, when there are floods in Germany, who is it who gets up Mansion House funds to assist the sufferers? Do we ever go begging to Germany in our misfortunes? Would money be offered gratuitously?

All this Mr. R. von Fischer-Treuenfeld, as a German with 25 years' residence in England, knows or should know, unless his association with a German firm here has blinded his sense of thinking for himself. As he is so anxious to contribute to a mutual understanding, let him begin at home, and teach his countrymen how much they owe to England.

Audi alteram partem.

[We do not think that any interests are served by a continuation of this discussion.—Eds. Elec. Rev.]

Steam Boilers.

My attention has been drawn to a leader in your paper criticising a paper I had the honour of reading before the Northern Society of Electrical Engineers. As you thought fit to criticise, perhaps you will kindly allow me the privilege of a reply. You commence your criticism by stating "but our readers will be disposed to attach very little weight to the arguments it is meant to convey, if they judge everything by one very glaring claim." Perhaps your readers might have understood your sarcasm if you had stated what claim you referred to. Then you state: "He also claims that the water-tube boiler has the same temperature all over." If you will be good enough to read my paper again, you will find I do not say this, but "One strong point in favour of the water-tube boiler is its very perfect circulation, which means that practically all the water in the boiler is at very nearly the same temperature."

I should, of course, have been quite wrong if I had stated that the boiler had the same temperature all over because the water forced into the boiler is comparatively cold. In the case I have been experimenting with it was about 100° F.; therefore it will be quite clear that the water in the back tubes was at a considerably lower temperature than 359° F., and the fact that the back of the boiler contains the coldest water is undoubtedly the reason the exit gases are so reduced in temperature.

Then you make the statement:—"The author makes a deplorable error in his reference to the steam jet adding to the heat by its conversion into water gas as it passes through the fire." One would have expected you to be certain of your facts before criticising in so determined a manner, and I think, upon further consideration, you will admit you are wrong.

You will, I have no doubt, agree that steam blown under the fire contains a considerable amount of heat, and in passing through the fire takes the heat from the bottom of the fire during its conversion to carbon monoxide and hydrogen which readily burn upon the top of the fire, and the heat thus given off helps very considerably in the combustion of the gases which are leaving the furnace, and in that way adds considerably to the heat of the furnace. I did not for a moment think or wish to convey the idea that by blowing steam under the fire, water gas was produced without considerable heat at the bottom of the fire being absorbed; but from actual tests with water-tube boilers, I have been convinced that the transference of the heat from the bottom to the top of the fire helps the combustion very considerably.

You then make the statement: "Steam is burnt hydrogen, and cannot be burnt again unless first dissociated by the employment of exactly as much heat as it gives back again on recombination." Had I made this statement, I should have considered you would have been justified in using a much stronger expression than "deplorable error," and I cannot understand your making such a statement.

Do you suggest that if high pressure steam is allowed to condense in an air-tight vessel, the result would be anything but water H_2O, or do you suggest that the ordinary method of manufacturing water gas, as adopted by many gasworks, is impossible, because this is clearly what you imply? Steam is not burnt hydrogen, but is vaporised water H_2O, and only requires more heat and the presence of carbon to be converted to H_2CO (water gas).

In your criticism of my remarks upon steam fittings, you have, I think, overlooked a very elementary point in connection with steam practice, and my reason for advocating a large steam valve, so that the steam may leave the boiler slowly, is based upon the fact that if a stop valve upon a boiler be partially closed, allowing the steam to leave the boiler at a great velocity, water is always carried with the steam; whereas, if the steam leaves the boiler slowly, the provision of an anti-priming pipe, which is, of course, fixed in most modern boilers, prevents priming.

Evidently my remarks upon the drainage of steam pipes were more clearly understood by referring members of the Society to the diagrams, but I should have thought any engineer interested in the subject would have been conversant with the American method of draining pipes I described in my paper, and certainly the editor of such an important paper as the ELECTRICAL REVIEW.

A. B. Mountain.

[If the circulation in a steam boiler be so good, it is hardly likely that the temperature of the back tubes would be so very low for the circulation in them must be rapid. In any case there is little chance of a single row of tubes reducing the gases to the point claimed. It is lower than obtains after the gases from a Lancashire boiler have passed by 100 4-inch economiser tubes. This repeated claim for water-tube boilers is mischievous and cannot be upheld by any reason, for if the furnace temperature be 2,500° and the final be only 350°, how is it we don't get evaporations of 13 to 14 lbs. per pound of coal? Where does all the heat go? There is so little to account for in the waste gases. As regards the steam jet the words seemed to convey the impression that the steam was useful other than as now explained. We do not understand Mr. Mountain's question as to steam being other than H_2O. We did not state that water gas as made in producers was impossible, but arguments as to water gas have no bearing on boiler furnace combustion. Steam introduced in a producer is dissociated and goes to form CO and H, and possibly hydro-carbons. It simply utilises part of the exothermic production of CO to split up water to its combustible constituents. Dissociation of water is an endothermic action, and if this were not carried out the producer gases would simply go away to the condenser pipes much hotter than they do when the heat has been partially utilised to split up water. Here water becomes a means to economy because it absorbs heat otherwise wasted. In a boiler furnace it cannot have such an effect, because the gases as produced on the grate are burned at once. No good can arise from steam, except so far as it helps the draught, or is necessary to the proper combustion of hydro-carbons to which its presence seems to be needful.

As regards the arguments as to steam valve, we really cannot see how, in a boiler properly fitted with anti-priming pipe, the degree of opening of the steam valve can have the slightest effect. The valve must of necessity be opened enough to let out all the steam made. If the valve is partly closed the rapidity of flow must be checked; and this is all it can do where there is an anti-primer. Without this pipe there might be some reason in advocating a large *valve opening*, but with it, the smallest valve that will pass all the steam is the best.—EDS. ELEC. REV.]

In your issue of the 24th ult. you say the author of the above paper "makes a deplorable error in his reference to the steam jet adding to the heat by its conversion into water gas as it passes through the fire," but you follow this by an assertion of your own "that moisture in a furnace may assist combustion, for it seems to be proved that its presence is necessary to combustion, its function being that of a carrier."

May it not be taken that the steam mentioned by Mr. Mountain and the moisture mentioned by yourself, Mr. Mountain having in mind the injection of such necessary amount of steam as may be required, should come under one head, as they are both chemically one and the same thing, viz., water vapour H_2O; and although there may not be actually a larger amount of heat generated by the conversion of this vapour into water gas the burning of this water gas into H_2O and CO_2 at the top of the fire, yet the fact that this heat is on the top of the fire makes it equivalent to a larger quantity; again, it helps combustion of the other gases, and thus Mr. Mountain may be rightly entitled to assume that the total useful and available heat is increased.

John Ed. Gresty.

Dust Destructors.

As my letter was the first to appear in the ELECTRICAL REVIEW objecting to the extraordinary claims of some one trying to boom the Shoreditch type of dust destructor, is my reason for again writing to you.

If Mr. Kershaw would simply, instead of writing long letters of refutation, quietly ask himself what led to the letter signed "Practical Experience," and those which followed in the ELECTRICAL REVIEW signed by different writers, he will find it was in consequence of a paragraph having gone the round of the press, that the district of Shoreditch was producing electric light for its requirements exclusively from the burning of the household and trade refuse collected in the parish.

When I read the paragraph in a newspaper I naturally thought such an absurd statement would soon be contradicted, but finding there was no contradiction and that the statement was referred to in publications of every possible kind, religious and otherwise, and keeping in view the mischief done in the past to a great industry, caused by claims of recent years under the headings "The Cheapest System"; "Electricity for Nothing by sale of bye-products," &c., &c., was the only reason for my writing and sending a mild protest to your influential journal.

Instead of repudiating the claims to which, as results show, there are no tangible facts to support, Mr. Kershaw, wisely or otherwise, brings out the lame excuse that they are obliged to use coal on Saturday afternoons and Sundays, in consequence of the dust carts knocking off work early on Saturdays.

Adjoining parishes would, no doubt, be pleased to send a supply free to last them over Saturday afternoons and Sundays.

It is quite clear an enormous weight and bulk of house and trade refuse is required to produce steam compared with a very small weight and bulk of coal, and when you put to one side speeches of professors and others delivered at the banquet to commemorate the opening of an important central station such as Shoreditch, and arrive at solid facts, the desirability of having a destructor in close proximity to valuable electric light machinery and private residences, simply for the benefit of the heat derived from its consumption, is a very doubtful advantage, especially if you take into account the disadvantages connected with the dirt and dust produced by its destruction where cleanliness and freedom from dust is of so much importance in the generating of electric light and power, to say nothing of the absolute necessity of having a reliable and uniform heat to produce the necessary pressure of steam for the engines.

These requirements cannot possibly be supplied from the varied qualities and conditions of refuse collected in any parish or district.

Of course, all credit is due to Shoreditch for its enterprise in attempting to solve the question of the use of a dust destructor combined with the production of electric light, but there is no justification for any one connected with the experiment claiming merits in connection with the enterprise which are not supported by actual facts.

Practical Experience.

January 8th, 1898.

The letter signed John Raworth is a somewhat curious contribution to the correspondence on the above subject. Its insincerity is palpable. The attempt at humour is pitiably grotesque. The condescension of its tone simply provokes a smile.

The writer confesses himself to be a student, but he has only learnt the rudiments of the subject.

Instead of sketching ridiculous and useless diagrams, he had better get his slate and pencil and help Mr. Kershaw to work out the following simple sums, taking care that he sees that the integrants are quite correct before adding them together. The sums are quite simple, and the student should have no difficulty in working them out:—

1. What is the cost of the power producing plant of the Shoreditch plant per kw. of mean output?

2. What is the cost of coal per actual output per kw. developed up to date?

If Student Raworth is prepared to accept a little wisdom, as he has certainly no relation to the Ex-Wisehead ("X. Y. Z.") of mathematics, and although he may be a nephew of "Aunty Humbug," he will in future know that the *rationale* and importance of an interrogation is independent of the mere name of the interrogator. When Mr. Student Raworth has learnt a little more of the science of dust destruction, in its relation to steam generation, he will recognise that the questions asked Mr. Kershaw in the various published letters are proper ones, and are interesting to the electrical community more than to individuals, and that their merit is independent of the names of the writers. Some of the questions have been repeated again by Mr. Brookman, and they demand an answer; the propositions as set forth by Mr. Raworth are school-boy like in their simplicity.

"The destruction of dust produces some heat." How true!
"Some heat will generate electricity." How wonderful!!
"*Ergo*, there is some saving." How absurd!!!

This is a perfect *reductio ad absurdum* in logical deduction. One might as well argue that because there is power in the rise and fall of tides, that this power is cheap; but the fact is, the impounding cost is so high, as to destroy any economic advantage.

The actual working results, compared with those of other plants and systems, are the only allowable figures for comparison. If the cost of plant attains a certain figure, the increased interest and depreciation may wipe out any advantage that cheap and nasty material may claim to possess.

Enquirer.

Some of your correspondents, Shoreditch and otherwise, appear to be much exercised in their minds with respect to the criticism passed upon these works, or the results, by your several correspondents. Surely this is very unreasonable. All that is wanted is reliable information, and that there appears to be some hesitation in supplying. I am quite in accord with you, Mr. Editor, and shall be only too happy to acknowledge the success of Shoreditch, should the installation prove a success even up to 75 per cent. of all that was promised. There is one matter to which reference has been made again and again, viz., the absolute silence of engineers who have a practical experience in the working of destructors year after year, I mean other than manufacturers and contractors; for instance, Laws, of Newcastle, Yabbacomb, of Bristol, and Jones, of Ealing. I think that the opinion of men such as these would be of value at the present time, and certainly would be appreciated by many.

X. Y. Z.

I am much obliged to Mr. Kershaw for his answers (as far as they go) to my questions. Had Mr. Kershaw stated two months ago that, owing to the destructor being worked under a guarantee for twelve months, it would be unwise to make any statement reflecting on the plant or appearing to reflect in any way on the performance, no doubt he would have saved himself and a number of your writers some trouble. Had I known it my questions would have not been asked, at any rate for some time to come.

I am delighted to find that the moonlighters have not seriously damaged Mr. Kershaw, and that he comes up as smiling as ever, determined to settle us all, anonymous or otherwise, with the twelve months' muzzle. However, I shall hope he will give us value for our questions when the time is up.

F. W. Brookman.

Rochdale, *January 11th*, 1898.

Dynamo Sparking.

I have long been a reader of your paper, which I have found of great use on several occasions, but I am now desirous of asking your assistance on the following subject.

I have in my case two dynamos, used chiefly for motor driving, each giving 750 amperes at 105 volts, and as the load varies considerably I have a deal of sparking at the brushes, though I have an attendant and engine man who alters the brushes when occasion arises, still they cannot attend to it as often as I would like.

I have thought, therefore, of applying some simple form of automatic brush rocker, and I propose to do it in the following way.

At the top of the magnet yoke fix a solenoid directly over the end of the brush-holder, and connect an iron core to this end, so that as the current increases through the solenoid it will attract the core and so lift the brushes forward, a suitable weight being placed on the brush-holder to reverse the motion when the load decreases.

The weight to be lifted would be 20 lbs. or so through a distance of 3 or 4 inches.

The difficulty I am in is to find the size of iron core and size and ampere-turns of solenoid that will lift this weight. I may say that it will not be necessary for the core to move until the load is about 100 amperes.

I would be greatly obliged if you could assist me in this matter. I have Thompson's "Electric Machinery," but this does not help me.

W. H. B.

[There are probably many of our readers who have experienced the same difficulty, and doubtless some of these will give our correspondent the benefit of their advice.—EDS. ELEC. REV.]

ELECTRICAL ENGINEERING AT HOME AND ABROAD.

MR. R. PERCY SELLON writes as follows to the *Times*:—

"Within the past few weeks I have had occasion to visit the leading Continental workshops representative of an industry which has already attained considerable proportions both in the Old World and the New, and is likely in the coming century to rank as one of premier importance as a field for the investment of capital and employment of labour. I refer to that of electrical engineering.

"My tour embraced the leading industrial centres of Germany, Austria, Bohemia, Hungary, Switzerland, and France, where electrical manufacture is being conducted on a large scale. Careful inquiry and observation upon the spot have elicited the following facts, which may be of some interest at this stage of a struggle between capital and labour, which, in the respects of organisation on both sides, of orderly conduct, and of the social, if not Socialistic, issues involved, marks a new era in the history of such disputes.

"Twenty years ago the electrical engineering, as distinct from its younger sister, the telegraph, industry was non-existent. All manufacturing nations therefore had an opportunity of 'starting level' towards the goal of industrial endeavour—viz., to supply their home and the world's markets with electrical products, for which the demand has grown and is increasing by leaps and bounds. If there were any odds at all, the advantage might have been held to lie with the country on whom rested the blessings of free trade, industrial experience, world-wide commercial relations, and unparalleled Imperial and Colonial possessions.

"What is the result? Briefly, as everyone interested in the subject is fully aware, that both American and Continental electrical manufacturers are underselling British-made goods in the neutral markets of the world, such as Central and South America, Russia, China, and Japan; have supplied a substantial proportion of the demand in our own colonies, where, alas! patriotism, when weighed in the balance against prices, is found wanting; and are to-day threatening, particularly in the respects of electric traction and power plant, to introduce ruinous competition in our home market itself.

"The capital invested in the electrical plant manufacturing industry in Great Britain has been estimated at not exceeding £4,000,000 to £5,000,000, in Germany at £10,000,000 to £12,000,000, and in the United States at £25,000,000 to £30,000,000. The output of manufactured electrical goods must be substantially in proportion.

"Various special causes—such as restrictive legislation, vested interests, and the proverbial caution which constitutes the commercial 'genius' of the British people—doubtless account in part for the relatively slow development of public electrical works, especially as regards electric traction and power, in Great Britain. But they do not account for the fact that Germany and America can undersell the English manufacturer in the common markets of the world which are equally open to all comers.

"The root cause of the latter phenomenon must be traced to the relative cost and methods of production in the different countries.

"Capital can be borrowed cheaper in England than in Germany or America. Materials, taken all round, cost about the same in the former, and decidedly higher in America. Hence the difficulty does not arise on these grounds. The explanation undoubtedly lies in the conditions on which labour is obtainable.

"I found that in the Continental workshops not only is a 60-hour week the invariable rule, but that the leading trades involved in electrical manufacture—machinists, fitters, and electrical artificers—are receiving on an average 25 per cent. less wage per week; or, taken with the fact that they work 10 per cent. longer hours than are usual in England, nearly 30 per cent. less per man per hour. This, of itself, is a serious handicap for the English manufacturer; but worse remains behind.

"English employers widely accuse the trade unions of attempting to dictate as to both the quality and quantity of labour to be employed in their workshops; of endeavouring to impose artificial restraints on the free and healthy productivity of both men and machinery by discountenancing piecework; by forcing highly-paid men to be employed on machinery, where a cheaper form of labour would suffice, and by limiting their members' daily output of work to a predetermined average, based on a low rather than a high standard.

"I was unable to meet with a single Continental employer who brought similar charges against the workmen's organisations in his country; and it need not be pointed out that, if correct, these charges knock the bottom out of the argument opposed by the mens' leaders here, that shorter hours in Great Britain will not prejudice industry, because the British artisan is a 'superior' or 'intenser' workman.

"The fact that American electrical engineering manufacturers can undersell British in the world's markets, in spite of their wage rates averaging some 30 per cent. higher, is pointed to by employers here in corroboration of these charges.

"I do not wish to suggest that the American or Continental workman is more disposed to abstain from agitation than the English workman because he is better satisfied with his lot. On the contrary, all students of the subject know that their dissatisfaction is chronic and profound; and probably most will agree in thinking that English militant trade unionism is a healthier manifestation of dissatisfaction than the explosive, though temporarily suppressed, socialism of the Continent, or the American workman's periodical struggles with despotic capitalism supported by special police and shot-guns. Many will go further, and hold that rational trade unionism is in the interests not only of the working classes but of society at large, as all ordered effort is better than chaos, and that it should not be discouraged.

"But into the socio-moral aspects of the question it is not possible here to enter. My object is to call attention to the influence which unsound economic doctrines on the part of British trade unions are having upon an industry which, although at present insignificant when compared with the staple industries of the world, is growing in importance every day, and is destined to become the most important section of the engineering trades in the near future.

"There are indications that the trade union leaders are willing to disavow, if they ever seriously held, these self-destructive doctrines affecting workshop management, regarded by employers generally as of far more vital consequence than the question of hours. If the unions through their leaders would clear up the present atmosphere of doubt and uncertainty by giving a clear and unequivocal statement of their attitude, the first and most important step will have been made towards a settlement alike honourable and advantageous to unionism by resulting in its willing recognition by employers, and acceptable to industrial capital by placing it in a position to compete favourably in the world's markets.

"I am, Sir, yours, &c.,

"R. Percy Sellon.

"London, *January 10th*."

Agency.—The International Trading Company have been appointed sole representatives in the United Kingdom of the Maschinenfabrik für Kabelfabrikation (Conrad Felsing, jun.), Berlin, O., and will make a special line of cable-making or wire-covering machinery.

Ajax Enclosed Arc Lamp.—We are informed that Messrs. Hill, Gifkins & Co., of 68, Victoria Street, S.W., have joined interests with Messrs. Beanland, Perkin & Co. as sole selling agents of this lamp. It has lately been considerably improved, and as now constructed for single parallel, multiple series, and constant current working, is considered to be by far the most practical of the enclosed types which have yet been introduced. It is now made in all sizes from 2½ amperes. For street-lighting purposes the new holophane inner globe, with clear outer globe, will be found specially suitable, as there is, by this arrangement, practically no loss in light, while it affords perfect diffusion. The alternating current type will be ready for delivery very shortly. The fullest possible guarantees are given with the Ajax lamp, both as regards satisfactory working and freedom from infringement of any patents.

Bankruptcy Proceedings.—A sitting of the London Bankruptcy Court was held before Mr. Registrar Linklater for the public examination of Charles Nigel Stewart, 39, Victoria Street, Westminster, whose accounts show liabilities £13,566 and a deficiency of £11,532. Under examination by the official receiver, the debtor stated that in 1895 he became chairman of the Universal Electric Carriage Syndicate, Limited, whose patents and stock were sold in the following year to the British Motor Syndicate, Limited. The last-named company formed a branch company in May, 1896, entitled the Great Horseless Carriage Company, Limited, and witness acted as manager, at a salary of £300 a year, until last June, when he resigned, owing to disagreement with one of the directors. He then joined the Directorate of the British and Continental Syndicate, Limited, which was formed to run a line of steamers between Southend and Ostend. He was liable for a considerable sum in connection with that syndicate, but had been advised that he had never been legally elected as a director. Then in July last he became a managing director of the Lombard Financial Syndicate, Limited, which was formed to work patents for photographs in colours, a telephonograph, unbreakable glass, and certain petroleum schemes. Witness attributed his insolvency to embarking on enterprises of which he had no previous knowledge, to Stock Exchange speculations, and to his liabilities in connection with the British and Continental Syndicate, Limited, and the Lombard Financial Syndicate, Limited. The examination was concluded.

Liquidation Notice.—The *London Gazette* contains notice to creditors of the Coventry Electric Tramways Company (in liquidation) to send particulars of debts or claims, and the usual particulars, to Mr. E. T. Pierson, 17, Hereford Street, Coventry, the liquidator, on or before February 21st.

Calendars.—Messrs. Veritys, Limited, have issued a calendar of the present year with a slip for each day. Some of the firm's specialities are nicely arranged in colours on the card.

A small handy wall calendar has also been sent to us by Messrs. Croggon & Co., Limited.

Changes of Address.—The National Electric Free Wiring Company, Limited, have been compelled to remove to larger premises. The registered offices will be at 8 and 10, Charing Cross Road, opposite their former premises.

Mr. Wm. Patterson, late of the City Wire Works, Newcastle-on-Tyne, informs us that he has removed to new works at Walker Gate, where he has increased facility for manufacture, and new plant.

New & Mayne, Limited.—On Wednesday, before Mr. Justice Wright, sitting as an additional judge of the Chancery Division, in the matter of New & Mayne, Limited (which was the petition of the company and the liquidator), counsel asked the Court to sanction a scheme of arrangement proposed to be made between the creditors of the company and the company. The nature of the arrangement was that the liabilities and assets of the old company should be transferred to the new company, and the one debenture holder, who held debentures securing £52,000 agreed to accept in satisfaction of those debentures £25,000 in debentures of the new company, and £27,000 in deferred stock of the new company. The unsecured creditors of the old company agreed to accept, in satisfaction of their debts, an equivalent amount of deferred debenture stock of the new company. Arrangements had been made for securing the working capital by giving power to the new company to raise £10,000 on security of the "A" debentures, which would take priority over the "B" debentures and deferred debentures stock. There were creditors to the amount of £5,020 who voted for the scheme, one creditor for £900 (whose debt was not allowed by the liquidator) voted against the scheme, and creditors for £117 did not vote. There was practically, therefore, no opposition to the scheme. His Lordship granted the application, subject to the filing of proper evidence that the meeting approving of the scheme was duly convened.

New Branch.—Messrs. Ames, Garrard & Co., have opened a branch establishment at 36, High Street, Northwich, Cheshire, where they are showing a varied selection of electric light fittings, accessories, &c. They have recently carried out a number of installations in the town, among them being both arc and incandescent lighting for business and residential premises. Other installation jobs are now in hand. The firm also lighted temporarily the table for the inauguration dinner of the directors of the Northwich Electric Supply Company on the 10th inst., the table being lighted by means of small lamps partially hidden by real flowers.

Partnership Notices.—Messrs. Clark, Forde & Taylor (Mr. Latimer Clark and Mr. Herbert A. Taylor) inform us that they have admitted into partnership Mr. R. E. Peake and Mr. Arthur L. Dearlove, who have for the past 20 years assisted them in their business of consulting, civil, electrical and cable engineers. Although we have only had the pleasure of meeting Mr. Peake on one or two occasions, Mr. Dearlove has been well known to us during the above-mentioned period, and he has occasionally contributed to our columns. We think the original members of the firm and their new partners are alike to be congratulated on the eminently wise step adopted. The style and address of the firm will be as heretofore—Clarke, Forde and Taylor, 4, Great Winchester Street, E.C.

With reference to our last week's notice under this heading, we are informed that Mr. Cortez Leigh is a partner in the firm of Lacey, Clirehugh & Sillar.

Mr. T. Scott Anderson informs us that he has taken into partnership Mr. Henry Harold Beit, A.I.E.E., and that in future the firm will be known as Scott Anderson & Beit, electrical and mechanical engineers, Royal Insurance Buildings, Sheffield. During the past year Mr. Scott Anderson has erected, besides other plants, nine electric welding plants for a great variety of work, and has also installed a complete lighting plant in a county asylum, and another in a large metropolitan hospital.

Personal.—We have pleasure in announcing that Mr. J. E. Lickfold, solicitor, has just taken offices at 4, Copthall Chambers, Throgmorton Street, E.C., where he is now practising on his own account. Mr. Lickfold was associated with the firm of Messrs. Lewis and Lewis, of Ely Place, Holborn, for over 30 years. Probably our readers have not forgotten how ably he handled all the cases in which the Electrical Review was opposed to Mr. C. B. Harness over the electropathic belt litigation, and we feel quite convinced that Mr. Lickfold will carry through equally well any legal business with which they may entrust him. We extend to him our best wishes for his success.

Mr. W. Arnot, M.I.C.E., M.I.M.E., M.I.E.E., late electrical engineer to the Glasgow Corporation, who is now carrying on business as consulting engineer, announces that his address is 79, West Regent Street, Glasgow.

Price List.—The Newton Electrical Works, Limited, have issued an 1898 price list, describing and illustrating the "Taunton" dynamos and motors. Photographic views are shown of electric haulage plant, launch and commercial motors, combined Taunton-Willans plant, combined gas engine and dynamo, transformers, switches, &c. Some instructions are given for fixing and working motors.

Staff Smoker.—A staff smoking concert of the City of London, Metropolitan and London Electric Lighting Companies was held at the Falstaff, Eastcheap, E.C., on Tuesday evening last, January 11th.

The Rumoured Amalgamation.—The *Westminster Gazette* says that what has been termed the Armstrong-Whitworth-Easton-Anderson combine does not exist, and is not likely to. As a matter of fact, the first-mentioned firm has nothing whatever to do with the important new undertaking, which will be styled "The Thames Ordnance and Engineering Company, Limited (with which is incorporated the business of Messrs. Easton, Anderson & Goolden, Limited)." The company, our contemporary understands, will be licensed by the great French firm of Schneider & Co., of Creusot and Havre, to manufacture the Schneider-Canet artillery; and by the German firm of Schuckert & Co., of Nuremberg, for the manufacture of electrical machinery under that firm's patents, everywhere save in Germany.

ELECTRIC LIGHTING NOTES.

Acton.—The Urban District Council of Acton having appointed Messrs. Kincaid, Waller & Manville to advise them on the subject of electric lighting, and at the time of so appointing them not having mentioned the fact that the Council had resolved to have two reports, Messrs. Kincaid, Waller & Manville, on hearing of this fact, felt it necessary to resign the appointment.

Asylum Lighting.—It is recommended that the works for the centralisation of the heating station and an installation for the supply of electric light be carried out at an estimated cost of £16,500. The cost per annum of gas, at 2s. 6d. per 1,000 cubic feet, is £1,100; cost of electric lighting, £978 17s. 4d.

Bangor.—The proposal to purchase a site in Garth Road for electricity works has been referred to a committee.

Bethnal Green.—A special committee recently recommended that the Vestry apply for a provisional order; that they arrange for an electrical engineer to report as to providing electricity in the parish. An amendment was moved that the recommendation be referred back. Both the motion and the amendment were defeated.

Bilston.—The scheme of the Midland Electric Corporation has been approved by the District Council on certain conditions. The Council reserves right to itself to apply for a provisional order for the district without interference on the part of the company.

Blackburn.—The Council has instructed the electrical engineer to obtain tenders for the additional electric lighting plant required during 1898, such extension not to exceed £8,000 under existing borrowing powers.

Brighton.—The Technical Instruction Committee has decided to purchase £360 worth of electrical plant to serve the double purposes of education and of lighting a portion of the building. The Committee has also resolved to appoint Mr. Armstrong as head of the Mechanical Engineering Department, at a salary of £200 per year, rising by annual increments of £25 to £250.

The Lighting Committee has appointed a sub-committee to go into the question of extensions to the public street electric lighting.

Burnley.—The Gas and Electric Lighting Committee are about to put down new plant at the electric lighting station, and are advertising for tenders for a high-speed engine and dynamo. The works are also being extended, building contracts for which have already been let. At the last meeting of the Town Council Mr. Councillor Parsons said that the Committee had entered into the question of a departure from the present system of engine with great hesitation and anxiety, but they had satisfied themselves that such a change was distinctly to the advantage of the works. Alderman Keighley expressed the opinion that the Committee were justified in adopting the proposed new plant.

The new type of engine is a high-speed compound condensing three-crank engine of 450 B.H.P.

Canterbury.—To-day (Friday) the City Council will have before them the report of the Electric Lighting Committee embodying the report of the consulting engineer, Mr. Robert Hammond, upon the tenders recently submitted for the supply and erection of plant and mains on the low tension system, for the municipal electricity supply undertaking. The Committee's recommendation is as follows:—

The Committee (acting upon the advice of the electrical engineer) recommend that the following tenders be accepted:—

Section.	Plant.	Name of firm.	Amount of tender. £	s.	d.
A.	Boiler house plant.—Lancashire boilers and accessories; mechanical stokers, feed pump, injector, economiser; electric motor.	R. Taylor & Sons.	1,512	0	0
B.	Engine house plant.—Steam dynamos and accessories: condensers, oil filter; steam, exhaust feed, blow-off and sundry pipes, valves, feed water and storage tanks, &c.	India-Rubber, Gutta-Percha Telegraph Works Company, Limited.	8,778	18	0
C.	Overhead travelling crane	James Spencer and Co.	235	0	0
D.	Switchboard and instruments ..	Crompton & Co., Limited.	999	0	0
E.	Accumulators	Chloride Electrical Storage Syndicate.	1,165	0	0
F.	Mains, insulated cables and trenching.	Fowler-Waring Cables Company, Limited.	5,836	0	0
G.	Public lamps, arc and incandescent street lamps, lamp-posts, and brackets.	Crompton & Co., Limited.	1,400	0	0
H.	Meters	S. Z. de Ferranti, Limited.	262	10	0
			£14,683	8	0

In addition to the plant included in the above sections, the estimate laid before the Local Government Board inspector included:—Connecting consumers to mains, £1,000; reinstatement of roads and footways, £500. The estimated expenditure in respect of the above items was £16,850, as against the totals of the recommended tenders, &c., of £16,183 3s., the difference of £333 3s. being more than covered by the amount included in the estimate for contingencies.

Cardiff.—Mr. W. Applebee has submitted to the Electric Lighting Committee a report upon the question of condensing water at the electricity works, and the saving effected thereby. The report sets forth the different methods of condensing, one of which has been tried at the electrical works for the past nine months, and has worked satisfactorily. The engineer recommends an extension of the system now in use, which is the cooling action derived by forcing the warm water at a slight pressure through a series of specially-shaped nozzles, which throw it into the air in jets of spray, which effectually cool it to the required degree. Mr. Applebee urged that over £100 per annum would be saved by adopting this system.

Chatham.—We understand that Messrs. Geipel & Lange have been appointed consulting engineers to the Chatham, Rochester and District Electric Lighting Company.

Cheltenham.—The net revenue of the electricity undertaking for the last quarter of 1897 was about £1,400 as compared with about £830 in the corresponding period of 1896.

Colchester.—The temporary lighting of the Military Hospital has been taken over by Messrs. Siemens Bros., Limited, and is working satisfactorily.

Croydon.—On Friday a Local Government Board inquiry was held into an application for permission to borrow several sums for municipal purposes, including £5,000 for electric lighting extensions to which we referred last week. The Town Clerk (Mr. E. Mawdesley) said they required the loan for the installation of the light in the South End, Croydon. There had been numerous requests for the light, and it was proposed to have a sub-station and additional plant at the central station. Prof. Kennedy said he had carried out all the electric lighting works for the Corporation, and the estimate was based on prices actually paid by the Corporation for work done. Alderman Miller gave his opinion as to the necessity of the work, and mentioned that there were 15,000 private lamps connected and 2,500 more had been applied for. There was no opposition.

Dundee.—The electricity rental collected for the seven months ended November 30th amounted to £1,629 7s. 11d., in December £356 8s. 9d., bringing out a total of £1,985 16s. 8d., or £277 4s. 4d. in advance of last year.

There is a proposal on foot to light High Street, Lochee, with the surplus electric energy from the Baths, and the electrical engineer (Mr. Tittensor) and the superintendent of the Baths are to report on the proposal, and give an estimate of the cost of erecting two or three arc lamps.

Eighteen electric arc lamps are to be placed in the centre of the city.

Ealing.—At last week's Council meeting, it was reported that there were now 13,412 8-candle-power lamps connected.

Elland.—The District Council has under consideration the advisability of providing the town with electric light. The committee, who visited Nelson and other towns recently, were struck with the limited space occupied by the Nelson installation. Gas at Elland is 2s. 6d. per 1,000 cubic feet, and is supplied by a private company.

Fort William.—The proprietor of the gasworks has intimated that the gasworks will be discontinued at the end of this month. Fort William will now depend entirely on electric light for illumination purposes.

Fulwood.—The District Council has consented to the application for a provisional order by the National Electric Supply Company, Limited.

Garston.—The proposal to erect a dust destructor plant in connection with the electric lighting installation is being strenuously opposed by ratepayers in Aigburth and Grassendale. The destructor site suggested is in the latter district, and it seems to be more the situation of the destructor than the idea of the destructor itself that does not meet the ratepayers' wishes. They will oppose the scheme when the Local Government Board inquiry is held, if necessary.

Glasgow.—A discussion arose at last week's meeting of the Corporation regarding the inefficiency of the arc lighting at St. Andrew's Hall. It was stated by Mr. Pettigrew, the Convener of the Lighting Committee, that if it were found that the system was defective the Committee was under an obligation to introduce a new system at the end of the present season. A report will be brought before the Corporation at that time.

Guildford.—The sixth annual report of the Guildford Electricity Supply Company shows that the subscribed capital is now £7,220, but it is anticipated that owing to the increased demand for the light further capital will shortly be required for the purpose of extending the works.

Hammersmith.—Remarkable success, says *London*, has attended the introduction of electric lighting in Hammersmith by the municipal authority. Although the works have only been in full operation for three months, the demand for current by private consumers is so great that the Vestry are about to expend a further sum of nearly £30,000 in extending the plant, so that the whole of the compulsory area mentioned in the provisional order will be covered. Only the main thoroughfares will at present be supplied with arc lamps, but as the station becomes more equipped attention will be paid to the principal side streets. There are now 104 arc lamps of 2,000-C.P. in the parish, and the extension will provide for 48 more. The number of consumers has grown to 108, and every week fresh applications are received from tradesmen and others. The scale of charges compares favourably with that of any other body in London. The Vestry is doing a good business in the supply of electricity for motive power at 2½d. per unit. A number of factories have taken advantage of the supply, as well as several large bakeries, including that belonging to Lyons, the great refreshment caterers. There are two scales for ordinary lighting purposes. Under the first a charge of 6d. per unit is made, but if the maximum demand as recorded on the indicator has been more than two hours per day, the charge is 4d. per unit for all current consumed in excess. The other alternative is a charge of 2½d. per unit, with a fixed charge of 1s. 3d. per quarter for the equivalent of every 8 C.P. lamp used at one time. The committee have ample scope for extending their plant, &c. The parish has acquired an open space of about five acres, and only about three-quarters of an acre is at present covered. The station is just on the borders of Fulham, and it is within the bounds of possibility that the Hammersmith Vestry may become the electric lighting authority for Fulham, now that they have thrown out their own scheme for establishing a system.

Hampstead.—The Vestry has appointed Mr. W. S. Ross, of Sunderland, and Mr. A. H. Seabrook, of Great Yarmouth, as assistant electrical engineers, to fill the vacancies caused by the resignation of Messrs. Hesketh & Morton.

Horsham.—A Committee has been appointed by the District Council to go into the subject of electric lighting, and a provisional order is to be applied for.

Huyton-with-Roby.—The District Council will support the British Insulated Wire Company's application for a provisional order.

Islington.—At the last Vestry meeting, in answer to Mr. Mills, the Treasurer said there had been no net profit on the working of the electric lighting installation. Mr. Towers further stated, in answer to Mr. Mills, that a sum of £1,554 2s. 2d. would be required per annum if the shorter period of repayment of loans prescribed by the Local Government Board were adopted.

Leeds.—At the last meeting of the City Council Mr. Wilson presented a report from the Parliamentary Committee as to the expediency of the purchase by the Council of the undertaking of the Yorkshire House-to-House Electricity Company, Limited, and moved its adoption. The Committee, he said, were of opinion that if the undertaking was to be purchased at all, it ought to be acquired as quickly as possible. The peculiar conditions under which the Corporation had power to acquire the undertaking made it abundantly clear that the longer the delay the greater the sum the Corporation would be called upon to pay. Up to December 31st, 1896, the House-to-House Electricity Company had expended upon works £105,377 6s. 1d., which had been discounted by the transfer to depreciation account of £4,300, thus leaving a sum of £101,077 3s 1d., certified by the official auditor of the company as the value of the undertaking at the date named. He mentioned these figures without, of course, necessarily accepting them as accurate. The Parliamentary Committee had come to the conclusion that it was the best thing the Corporation could do to lose no time in possessing themselves of the undertaking, and thus repair a mistake they made earlier. It might be there was some reason for not moving in this direction before. People had been afraid to touch electricity, but that fear had now to a great extent disappeared. The experimental stage in electric lighting had passed, and the Council would do wisely in adopting what was the unanimous recommendation of the Parliamentary Committee. The resolution was carried. Mr. Wilson moved a resolution that application be made by the Corporation to the Local Government Board for a provisional order to issue irredeemable or redeemable stock, or for powers otherwise to enable them to acquire the House-to-House Company's undertaking. He contemplated considerable difficulty in getting the necessary powers to purchase. The resolution was carried, and a third resolution was adopted empowering the Council without prejudice to their Parliamentary powers, to open negotiations with the Electricity Company for the purchase of their undertaking.

Lincoln.—The Local Government Board has sanctioned the borrowing of £1,500 for land and £19,150 for electric lighting purposes. Lincoln £3 per cent. stock is to be created to raise the sum.

Liverpool.—At a meeting of the Lighting Committee last week, it was resolved that two sets of electrical plant be ordered from Messrs. Willans & Robinson at a cost of £1,727, and that the work be proceeded with as early as possible for the Oldham Street and Paradise Street Stations. Efforts are being made to obtain in Lodge Lane and Smithdown Road the necessary ground for substations. It was also resolved that the electric main be extended along Scotland Road, at an estimated cost of £741, thus completing the system in that neighbourhood.

Llanrwst.—Mr. G. R. Peers, electrical engineer, Colwyn Bay, has written to the District Council, setting forth the conditions upon which he would be prepared to light the town with electricity. The Council is favourably disposed toward the scheme, but will first submit the matter to the ratepayers.

London.—The St. Luke's Vestry has referred it to a committee to inquire into and report upon a scheme for the better lighting of the parish with electricity or other light.

Lynn.—The Electric Lighting Committee is authorised to engage the services of an expert to advise and report upon electric lighting.

Manchester.—The City Council has agreed to the proposal mentioned last week, to purchase the plot of land in Stuart Street, Bradford, containing an approximate area of 83 statute acres, including one-half of Stuart Street, and up to the north side of the Manchester and Ashton-under-Lyne Canal, for the establishment of a new generating station, at 2½d. per square yard per annum and 21 years' purchase—equal to 4s. 4½d. per square yard freehold. The Corporation will be able to put on the land plant to supply the whole city of Manchester with electricity for lighting and traction purposes.

Merthyr.—At last week's District Council meeting the Clerk explained that up to the present time no steps had been taken to comply with the provisional order, and Messrs. Howell & Co. now sought to have the order transferred to Messrs. Crompton & Co., with whom they had made arrangements for carrying out the undertaking. The Council has passed a resolution objecting to the suggested transfer and declaring in favour of the order being revoked unless Messrs. Howell & Co. commenced the work at an early date.

Mumbles.—Mr. W. Weaver has made an offer to the Local Board to light a large area of the district by electricity at an annual cost not exceeding that at present paid, the Council to either obtain powers itself and transfer to him at his cost, or to consent to him applying for the power. The clerk is to report on the scheme.

Norden.—The District Council has had the main road lighted electrically, the contract being carried out by Mr. G. L. Adamson, electrical engineer, Smallbridge. The power house contains a 2 brake H.P. gas engine, made by the National Gas Engine Company. This engine drives a dynamo. The poles on which the line is carried are 50 yards apart, and on each alternate pole is fixed a strong lamp bracket. The lamps, which are of Edison-Swan manufacture, are 25 C.P. The formal inauguration ceremony took place in the power house at Wolstenholme some days ago.

Norwich.—The Blofield District Council has consented to the proposed application of the Norwich Electricity Company, Limited, for electric lighting powers for its district. The St. Faith's Council has also approved.

Oldbury.—Application was made by the Midland Electric Corporation and Power Distribution Company for the consent of the Council to their draft provisional order giving them power to supply the district with electric light, but the Council refused.

Otley.—A proposal was recently made at the District Council that tenders be invited from electrical engineers for lighting the streets of Otley with the electric light; but after discussion, the matter was referred to a committee for inquiries.

Penarth.—The District Council will consent to the proposed provisional order promoted by a company, on condition that certain clauses are inserted.

Peterborough.—The special Council meeting, to which we referred last week, was held at the Guildhall on 5th inst., to consider the refusal of the Local Government Board to allow the Corporation to borrow £15,000 for electric lighting on the ground that the borrowing powers of the Corporation were not sufficient. The discussion chiefly considered what reply should be sent to the board. The reply approved by the Council, after a great deal of talk, in which much that was unnecessary was said, gave a statement of the Corporation's borrowing powers, and referred to the fact that a company is applying for electric lighting powers. The Council is anxious that the undertaking should be a municipal one, and urges the board to either hold an inquiry forthwith, or receive a deputation on the matter.

Salford.—The Council is applying to the Local Government Board for a £50,000 loan to cover the cost of the land, building and machinery, to extend the electric light undertaking in accordance with the estimate submitted by the engineer. When the proposal came before the Council, Councillor Haworth stated that it was some nine months since the Electric Lighting Committee was appointed to take charge of this question. One of the first things they took in hand was to consider how the loss arose, and how to remedy it. When they took charge they had 11,400 8-C.P. lamps connected with the mains; at the present time they had 22,000, and in a week or two he anticipated they would have several thousand more. In money spent upon wages, coke and stores during the nine months they had effected a saving of £124, although they had turned out so much more current during that time. Their revenue had increased from £1,005 to £1,469, and this in spite of the fact that they were selling the current at a reduction of 33⅓ per cent. as compared with 12 months ago. That was a very satisfactory state of things for so short a time. One of the greatest obstacles they had had to contend with was that a number of customers connected with the mains only took the Corporation light when they had a breakdown in their own machinery. They had since altered the system of charging, so that anyone taking the current, for however short a time, would have to pay a charge per lamp, and they found that that had worked out in a satisfactory manner. In the June quarter, 1896, the number of units sold was 5 026, whereas in the same quarter this year it had increased to 11,513. In the September quarter, 1896, they sold 6,843, and the number had increased to 16,234 in the corresponding quarter of 1897. Next quarter there would be a further increase, and they estimated they would, at the end of the year, reduce the loss by fully £1,000. He desired to impress upon them that they had progressed as far with the scheme as it was possible at present. They had, as a matter of fact, more customers than the mains would supply. They had 22,000 lamps connected at the present time, although their power was only calculated to sustain 12,000 lights at one time. The committee had gone into the matter carefully, and proposed to build a new station in a spot which would be convenient for future developments. They had such a plot of land in view.

Sheffield.—The minutes and correspondence of the Parliamentary Committee re the proposed purchase of the electricity works and the removal of the difficulties at present in the way thereof, came before the Corporation on Wednesday. The recent decision by Mr. Justice North is referred to, and it is recommended that the Council apply to the Local Government Board for a provisional order amending so much of the Local Government Board's Provisional Order's Confirmation (No. 9) Act, 1892, as will enable the Corporation to issue irredeemable stock to an amount sufficient to raise the purchase money required for the purchase of the undertaking of the Sheffield Electric Light and Power Company, Limited, under the powers conferred by Article 60 (1, of the Sheffield, 1892, provisional order. A letter has been received from the Local Government Board stating that the Corporation's application for an order empowering the issue of irredeemable stock is under consideration. The Board point out "that for many years past they have entertained objection to the issue of irredeemable securities by local authorities, and they have been accustomed to represent their views in this matter to Parliament in connection with proposals affecting stock contained in bills promoted by local authorities. It has not been the practice of Parliament during recent years to authorise the issue of irredeemable stock, but on the contrary the Local Acts of recent Sessions relating to the issue of stock have made provision for the redemption of the stock at par within a specified period. The Board also consider that it may be doubted whether a provision such as is contemplated would not be in contravention of the Standing Orders, which (see Standing Order 173 (A), House of Commons) provide that a committee to whom a bill is referred shall not in any case allow a longer term than 60 years for the redemption of any charge or debt under the bill. Having regard to all the circumstances, it appears to the Board to be desirable that any legislation such as is suggested in the matter of the purchase of the undertaking by the City Council, should be by private bill." The Parliamentary Committee advises that notwithstanding this advice, further representations be made to the Board in conjunction with the Leeds Corporation who are seeking a provisional order similar to that which the Sheffield Corporation are applying for; that the chairman and the deputy-chairman, together with the town clerk, be appointed to join a deputation from Leeds to wait on the Right Hon. Henry Chaplin, M.P., the President of the Local Government Board, with a view to induce him to grant the provisional orders applied for, and that the members of Parliament for the city be requested to attend the proposed interview with the president of the board. The Sheffield Electric Light and Power Company has written to the Corporation, under date December 15th, saying that although Mr. Justice North's decision established that the Corporation were not in a position to require the company to sell, they were prepared—if the Corporation desired to purchase—to consider an offer, but on the basis that the sale took effect as from December 31st, 1897, or some subsequent date to be agreed upon. Certain matters connected with the company which would shortly have to be dealt with, rendered it necessary that any offer by the Corporation should be made without delay. The chairman of the Parliamentary Committee reported that the terms on which the committee had negotiated with the Sheffield Electric Light and Power Company, prior to July 5th, 1897, were that the Corporation for each £100 of the sum properly expended by the company upon their undertaking, and chargeable to capital account, should, on completion of the purchase, issue or transfer to the company, or as they might direct, £220 of new 2½ per cent. redeemable Sheffield Corporation stock, such stock not to be redeemable before the year 1925, and to be issued free from stamp duty; that the balance of the purchase money in respect of the amount payable to make up the dividends to 5 per cent. per annum should be paid by the Corporation to the company in cash on completion of the purchase, and that the date of the purchase should be May 31st, 1897. The chairman also reported that certain heads of agreement had been drawn by the late town clerk on behalf of the Corporation, and Mr. Moore on behalf of the company, which provided for certain other matters consequent on the purchase and transfer of the undertaking of the company. The Committee resolved that the chairman and deputy-chairman be authorised to negotiate with the representatives of the Sheffield Electric Light and Power Company on the terms mentioned above, namely, £220 of Sheffield Corporation 2½ per cent. Redeemable Stock for every £100 of the sum properly expended by the company upon their undertaking and chargeable to Capital Account, provided that the basis be that the sale take effect as from September 29th last, and not from December 31st, and that the amount of such capital expenditure shall not in any event exceed £112,000, any further expenditure properly made being repaid to the company with 5 per cent. interest from the date of payment.

The Committee recommends that the scheme of the General Power Distributing Company, so far as it concerns Sheffield, be opposed by the Corporation.

Stirling.—Professor Kennedy, the electrical engineer employed by the Corporation, visited the reservoirs at Touch on Saturday with a view to ascertaining whether water-power could not be utilised to drive the dynamos. He was accompanied by the Lighting Committee.

St. Pancras.—It is understood that the Vestry is to extend the electric lighting mains to the whole of the Highgate part of its district. The outlay is estimated to be about £7,585.

Sunderland.—The Lighting Committee have agreed on an application by the Sunderland Guardians to supply the Union Workhouse with electric light, to carry the mains to the Workhouse gates at a cost of £1,200.

Train Lighting.—The express trains of the Caledonian Railway running between Edinburgh and Glasgow have now been fitted up with the electric light.

Wallasey.—It has been decided to reduce the charge for electric light by one penny per unit, from 7d. to 6d., with proportionate reductions for large users.

West Bromwich.—The Town Council will oppose the application of the Midland Electric Power Distribution Company for a provisional order.

West Ham.—On Thursday, last week, a Local Government inquiry was held at the Town Hall into the application of the District Council for sanction to borrow £11,573 for electric lighting and other purposes.

Whitechapel.—The Electric Lighting Committee has been paying a visit to the Brighton Corporation electricity works in connection with its proposed installation, for which a site was recently purchased by the District Board.

Winchester.—The Winchester Electric Light and Power Company recently deposited with the City Council its plans, together with a description of the system proposed. It was proposed to get the assistance of some competent person, having technical knowledge, to advise.

Windsor.—The Windsor Electrical Installation Company have just completed a contract for the supply of steam from the central lighting station to one of the Windsor hotels for heating, cooking, and laundry purposes. The experiment has been going on for some time, and has proved so successful that a contract for five years' supply has been entered into.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

Blackpool.—At last week's Town Council meeting the question of the proposed construction of a tramway on Queen's Drive, in Claremont, was discussed. Mr. Brodie, chairman of the Tramways Committee, moved that the recommendation of the committee in favour of the proposal be adopted, and also that the overhead electric system of traction be used. Mr. J. Bickerstaffe opposed the recommendation, arguing that the time was not opportune, especially as the Board of Trade had not sanctioned the overhead system. It was also pointed out that the poll of the town on the matter of a new tramway on the middle walk in Claremont Park had not yet been taken. Mr. Grime said the present line at that end of the town was worked at a loss. If the new tramway were laid, some £2,000 or £3,000 would be earned. It would be a convenience to visitors and to residents alike, besides being remunerative. Mr. Ward spoke strongly in favour of the scheme. He said the time was opportune, because the North Shore works were about to be completed. All the road would have to be pulled up, and it would cost a good deal more if the work were not done now. Mr. Bickerstaffe's amendment was defeated by 13 votes to 11. A further amendment was proposed, to the effect that the lines for the new tramway in the Park be laid down, but that no steps be taken to fix the system of electric traction for several months. During the discussion, it was pointed out that the Board of Trade had refused to allow the Corporation to adopt the overhead system on the Promenade. Now the Council wanted to utilise the powers they already possessed to work a proposed tramway through the Park on the overhead system. It was contended that if the Council went on with this, they would be administering a slap in the face to the Board of Trade, and accordingly the amendment was strongly objected to. On the other hand, hope was expressed that, despite the recent pronouncement, the Board of Trade would sanction the trolley system in the Park. At any rate, a deputation would wait upon the Board, and ask why so many other towns should be given permission to adopt the overhead system, while it was refused to Blackpool. The expensive working of the accumulator system would also be pointed out, and if necessary, demonstration could be made of the complete safety of the overhead system. In the end the amendment was defeated, and the original scheme will proceed.

Derby.—The Council has resolved, in connection with the proposed purchase of the tramways, to seek expert advice as to the value of the undertaking, and the offer to be made.

Dover.—The Town Council last week decided to order three more motor cars for the electric tramways. A quicker service is to be given, and these cars are required for the purpose.

The returns of the tramways for the week ending January 1st were:—Passengers carried, 36,236; fares taken, £150 19s. 8d.; average per day, £25 3s. 3d. The total receipts from the commencement of operation (about four months) come to £1,931 odd. The expenditure is estimated at £100 a week.

Electric Cabs.—At a meeting of a number of gentlemen interested in the motor car industry, at the Queen's Hotel, Leeds, on Thursday last, one of the electric cabs, similar to those running in London, was on view. The meeting was held under the auspices of the Electrical Vehicle Company. The vehicle was in charge of Mr. Bersey. At the conclusion of the trials the company was entertained to luncheon, the chair being occupied by Mr. Holmes, of Messrs. Holmes & Co., of Newcastle.

Glasgow.—In connection with the recent controversy regarding the new form of electric car to be used on the Springburn section, a member of the Town Council has given notice of the following motion:—"That, in view of the dangers likely to arise to passengers entering or leaving the cars by a door in the centre of the side of the cars which at present are being built, the Tramways Committee be instructed to have a tramway car constructed as speedily as possible with entrances and exits at either end."

Halifax.—The Town Council has resolved to apply to Parliament for a bill empowering it to do certain works, among them being power to lay down and work electric tramways through twelve districts, and to widen several streets.

Isle of Man.—The Isle of Man Electric Tramway Company have, according to the *Daily Tenders*, entered upon possession of all the land acquired for the extension of their line from Laxey to Ramsey.

London.—*Daily Tenders* says that applications are being invited for taking up the leave to provide and run an electric tramway on well patronised grounds, near London, now being opened to the public. Applications, by appointment, for further particulars to Messrs. Taylor & Field, 14, Victoria Street, Westminster, London, S.W.

Newcastle.—The Corporation last week had a lengthy discussion on the proposed taking over and working of the tramways as a municipal concern at the expiry of the present tramway lease. The debate was adjourned until January 26th.

Norwich.—The Blofield District Council will not consent to the proposed application of the Norwich Electric Tramways Company for tramway powers which would affect their district.

Sheffield.—The work for the extension of the tramway system has been started in earnest, and the men are busily engaged on the Nether Edge section. These new rails are to be laid as soon as possible on concrete foundations, and it is expected that the electric cars will be in working order in this part of the city by June.

The Jungfrau Railway.—The latest report on the progress of the Jungfrau Railway shows, says the *Times*, that the work of construction is being pushed forward, notwithstanding the severe weather prevailing this winter in Switzerland. Water power to the extent of 2,400 horse-power is now available at Lauterbrunnen, half of this force being utilised for the dynamos employed in the boring of the Eiger glacier tunnel. The mountain stream has been diverted from its course for a distance of six miles, extending from the water wheelhouse to Scheidegg Station and the Eiger glacier, while the open line between the Scheidegg and the glacier, with its tunnel of 88 yards, is finished in its main details, so that the electric railway over this portion will probably be opened in the first half of next June, and in time for the tourist season. The principal tunnel has been carried to a distance of 164 yards by hand boring—chiefly done by Italian workmen—and the preliminaries for tracing out the great tunnel have been accomplished after some two years of labour. The rock is found to be excellently adapted for tunnelling, and experiments on the Jungfraujoch have proved that it is reached at a depth varying from 80 feet to 100 feet under the snow, instead of at 230 feet, as was at first expected. In connection with Swiss mountain railways, it may be mentioned that the opening trial of the Gornergrat Electric Railway has proved satisfactory. The line was completed a short time ago, and it is to be opened for passenger traffic early in the spring.

West Australia.—At a recent meeting of the West Australian Mining Company, in London, the chairman said that the company had secured a valuable concession for the construction of electric tramways in the city of Perth. The concession was granted by the municipality in April last.

TELEGRAPH AND TELEPHONE NOTES.

Pacific Cable.—Speaking recently at East London, Sir John Gordon Sprigg, the Premier of Cape Colony, referred to the proposal made by the Afrikander Bond for the laying of a deep sea cable to the mother country, and said that while in England he had negotiated upon the matter, the proposition being that the cable should go from England to Gibraltar, and thence *via* Sierra Leone, Ascension, and St. Helena, to Capetown, whence it would pass overland to Durban, and from Durban be carried to Mauritius and to Perth, West Australia. The Premier added that should this scheme be carried out he would submit to Parliament that the Cape as its share should bear the cost of construction to Capetown and Durban. This idea, however, was apart from the naval contribution scheme.

Reductions in Rates to the West Indies.—The traffic manager of the Direct United States Cable Company announces the following important reductions in the rates over the wires of this company to the following places in the West Indies, and which come into force immediately:—Antigua reduced from 7s. 5d. per word to 4s. 7d.; Barbadoes reduced from 7s. 10d. per word to 5s.; Dominica reduced from 7s. 3d. per word to 4s. 5d.; Grenada reduced from 7s. 9d. per word to 4s. 11d.; Jamaica reduced from 5s. 10d. per word to 3s.; Porto Rico reduced from 8s. 8d. per word to 5s. 10d.; St. Croix reduced from 8s. 3d. per word to 5s. 5d.; St. Kitt's reduced from 7s. 9d. per word to 4s. 11d.; St. Lucia reduced from 7s. 7d. per word to 4s. 9d.; St. Thomas reduced from 8s. per word to 5s. 2d.; St. Vincent reduced from 7s. 7d. per word to 4s. 9d.; Trinidad reduced from 8s. 1d. per word to 5s. 3d.; British Guiana reduced from 10s. per word to 7s. 2d.

Rugby Telephones.—The National Telephone Company opened an exchange at Rugby on Thursday last week.

The Telegraph Wire Export Trade.—The last month of 1897 proved to be the busiest one of the whole 12 months, in so far as the exports of telegraph wire and apparatus connected therewith are concerned, the total value being given as £172,140, as against only £34,341 in the preceding month, and only £118,720 in December, 1896. This large increase had the result of making the 12 months total the best recorded for several years past, as will be seen from the following figures:—1897, £1,001,102; 1896, £857,174; and 1895, £782,375. The trade is one that is subject to great fluctuations, as while the lowest monthly total was £34,341 (in November), the highest was that recorded in the last month of the year—£172,140.

The Telephone Service.—The Commission of Sewers passed the following resolution last week:—"That application be made to the Treasury, asking for an inquiry into the cost and efficiency of the telephone service in London, and all other matters relating thereto."

Trunk Telephones.—The new trunk telephone line from Aberdeen to Inverness, *viâ* Peterhead, Banff, and Elgin, was opened to the public on 6th inst., and these towns are now placed in direct telephonic communication with the rest of the country.

CONTRACTS OPEN AND CLOSED.

OPEN.

Ashton-under-Lyne.—February 2nd. The Baths Committee want tenders for the installation of the necessary wires and fittings for the electric lighting of the Corporation Baths. Consulting engineers, Messrs. Lacey, Clirehugh & Sillar. See our "Official Notices" for particulars.

Bilbao.—February 28th. The Secretary of State for Foreign Affairs has received a despatch from Her Majesty's Consul at Bilbao, reporting that the provisional board appointed in connection with the electric tramway which it is proposed to lay from Zumarraga to Zumaya, in the province of Guipuscoa, invite plans and tenders, to be received by February 28th, for the construction and equipment of the line. Further particulars of the conditions of the tenders for the above-named tram line and branch, which together measure 30 miles, may be inspected at the Commercial Department of the Foreign Office any day between the hours of 11 and 6.

Bedford.—January 24th. The Corporation want tenders for the supply and delivery of vulcanised rubber cables. See our "Official Notices" January 7th.

Blackburn.—January 22nd. The Corporation want tenders for a 500-kw. continuous current steam dynamo, and a 120-kw. steam alternator. Consulting engineer, Mr. E. M. Lacey. See our "Official Notices" January 7th.

France.—January 22nd. The Municipal Authorities of Neuilly-sur-Seine are inviting tenders for the concession for the establishment and working of a central electric station in the town. Particulars from, and tenders to, La Mairie de Neuilly-sur Seine.

Germany.—January 29th. The Hanover Direction of the Prussian State Railways is inviting tenders until the 29th inst. for the supply of 39,000 porcelain insulators, 1,000 screw supports, 300 tons of galvanised wire and about 2¾ tons of insulated wire. Particulars from, and tenders to, Die Königliche Eisenbahn Direction, Hanover.

Gloucester.—January 18th. The Electricity Committee want tenders for boilers, dynamos, overhead crane, switchboard, accumulators, mains, arc lamps, meters, &c., for electric lighting. Consulting engineer, Mr. Robert Hammond. See our "Official Notices" December 10th.

Leicester.—January 31st. The Leicester Corporation invites designs and tender for motor vehicles for the collection of house refuse. Specifications and particulars, with drawings, to be sent to the Chairman of the Sanitary Committee, to the office of Mr. E. Geo. Mawbey, C.E., borough engineer, Town Hall, Leicester.

Newport.—January 24th. The Electricity Committee want tenders for the supply and erection of mains, transformers, switch gear, cast-iron posts and for arc lamps. Consulting engineer, Mr. Robert Hammond. See our "Official Notices" January 7th.

Newport.—January 25th. The Corporation want tenders for temporary electric lighting plant for the Wentwood Waterworks, for arc and incandescent lighting. See our "Official Notices."

Rochdale.—February 19th. The Corporation want tenders for steam dynamos, balancer, and boosters, &c. Engineers, Messrs. Lacey, Clirehugh & Sillar. See our "Official Notices."

Roumania.—March 15th. Tenders are being invited by the General Direction of the Roumanian Post and Telegraphs in Bucharest for the supply of 56,000 metres of galvanised iron and steel wire.

Spain.—February 1st. Tenders are being invited by the Municipal Authorities of Tarifa (Cadiz province) for the 20 years' concession for the lighting of the public streets of the town by electricity, acetylene or gas. Tenders to El Secretario del Ayantamiento de Tarifa (Cadiz) from whom particulars may be obtained.

St. Marylebone.—January 17th. The Guardians want tenders for electric light wiring and fittings at their new administrative buildings of their workhouse in Northumberland Street, W. Particulars from the Guardians' Architect, Mr. A. Saxon Snell, F.R.I.B.A., of 22, Southampton Buildings, Chancery Lane, W.C.

Stockport.—January 27th. The Corporation is wanting tenders for various plant and machinery for electricity supply works at Millgate, Stockport, including Lancashire boilers, steam dynamos, feed water heater, storage battery, electrical instruments, electrical connections, wiring, &c., at the generating stations, underground cables. Electrical engineer, Mr. James N. Shoolbred, 47, Victoria Street, S.W. See our "Official Notices" this week.

Wallasey.—January 20th. The District Council wants tenders for the supply and erection of a 5-ton hand-power overhead travelling crane for the electricity works. Engineer, Mr. J. H. Crowther. See our "Official Notices" this week.

Wimbledon.—February 2nd. The District Council wants tenders for the supply, delivery and erection of water tube boilers, condensing plant, overhead crane, high speed steam engine and alternator, switchboard, underground mains, conduits, &c. Consulting engineer, Mr. A. H. Preece. See our "Official Notices" for particulars.

CLOSED.

Blackburn.—The following are the tenders to Mr. E. M. Lacey's specification for eight 60-passenger cars for the Blackburn Corporation:—

	£	s.	d.
Crompton & Co.	6,620	0	0
Electric Construction Company	6,087	0	0
British Thomson-Houston	5,579	15	8
Laing, Wharton & Down	5,557	11	0
R. W. Blackwell	5,450	0	0
Siemens Bros. & Co.	5,444	0	0
Westinghouse Electric Company	5,296	0	0

The accepted tender is that of Messrs. Siemens Bros. & Co. who are already supplying the generating plant and are erecting the overhead line.

Dewsbury.—The Council has accepted the tender of Messrs. Crawshaw and Warburton for coal for the electricity works.

Hammersmith.—The Vestry has accepted the tender of the Electrical Construction Company, for the supply of two alternators, exciters, &c., at £3,600.

Leeds—Messrs. S. Dixon & Son have secured the contract for electric fittings, &c., for the City Square lighting.

Liverpool.—The Lighting Committee has given out a contract to Messrs. Willans and Robinson for two sets of electrical plant at £1,727.

Yarmouth.—Three tenders were received by the School Board for installing the electric light at Nelson School, as follows:—Crompton & Co., £88 10s.; Gray & Palmer, £86 5s.; and Mr. Pank, £75. The Board's architect's estimate was £65. Mr. Pank's tender was accepted.

FORTHCOMING EVENTS.

1898.

Friday, January 14th, at 8 p.m.—Institution of Civil Engineers. Students' meeting. Paper to be read:—"Mechanical Draught." By R. Gordon Mackay, Stud.Inst.C.E. Sir Albert J. Durston, K.C.B., M.Inst.C.E., will preside.

Saturday, January 15th, at 3 p.m.—North-East Coast Institution of Engineers and Shipbuilders—Visit to inspect the electric power transmission plant installed at the works of Messrs. Thos. Richardson & Sons, West Hartlepool.

Wednesday, January 19th.—Institution of Electrical Engineers Students' meeting. Discussion on "Accumulator Traction."

Thursday, January 20th.—Royal Institution. First of a course of three lectures by Prof. Dewar on "The Halogen Group of Elements."

At 2.30 p.m.—Institution of Civil Engineers—Students' visit to the Central London Railway Works.

At 8 p.m.—Chemical Society. Ballot for the election of Foreign Members. Papers as follows:—"The Action of Caustic Alkalies on Amides," by Julius B. Cohen, Ph.D., and Edward Brittain, B.Sc.; "The Formation of Monomethylaniline from Dimethylaniline," by Julius B. Cohen, Ph.D., and H. T. Calvert, B.Sc.; "Note on the Aluminium-Mercury Couple," by Julius B. Cohen, Ph.D., and H. T Calvert, B.Sc.; "Action of Chloroform and Alkaline Hydroxides on the Nitro-Benzoic Acids," by W. J. Elliott, M.A.; "Researches on the Terpenes.—II. On the Oxidation of Fenchene," by J. Addyman Gardner, M.A., and G. B. Cockburn, B.A.; "The Preparation of Pure Iodine," by Bevan Lean, D.Sc., B.A., and W. H. Whatmough.

Friday, January 21st, at 5 p.m.—Physical Society, at the rooms of the Chemical Society, Burlington House. Agenda:—(1) "On Electric Signalling without Conducting Wires," by Prof. O. Lodge, F.R.S.; (2) A Tesla Oscillator will be exhibited by Prof. S. P. Thompson, F.R.S.

At 8 p.m.—Institution of Junior Engineers, at the Westminster Palace Hotel. Lecture on "Laboratory Testing Machines, and the Latest Example," by Prof. A. C. Elliott, M.Inst.C.E., Hon.M.Inst.J.E., of Cardiff.

Saturday, January 22nd, at 3 p.m.—Institution of Junior Engineers—Visit to the Engineering Laboratory of the Central Technical College, South Kensington. Demonstrations by Prof. W. C. Unwin, F.R.S, Past Pres. Inst.J.E.

NOTES.

Photography and Light.—The New York correspondent of the *Standard* says that Mr. Tesla announces that his vacuum tubes are now so perfect, as to take photographs surpassing flash pictures. Two seconds' exposure was used at a distance of 4 feet from a tube, with a radiating surface of 200 square inches, giving 1,000 candlelight from current oscillations of 2,000,000 per second. Mr. Tesla says that his system will give an equivalent light, without heat, from tubes the size of ordinary incandescent bulbs. This may be more scientific, says the *Standard* writer, but it is less amazing than the declaration by an inventor, named Nickum, heretofore obscure, that he has obtained a brilliant permanent light from chemicals within a sealed globe. There are reputable witnesses of Nickum's light, which gives a cool, steady, mellow glow theoretically for ever, being inextinguishable, and without waste. When it is not wanted, it is laid away in a cupboard, or otherwise obscured. The only flaw in the story is that Nickum declares that the discovery, which his light attests, also disproves the theory of gravitation, and shows that a vacuum is impossible. The perpetual vibration of atoms is the base of his principle, which as yet is equally difficult of proof or disproof, those admitted to his confidence having no scientific authority.

Coherers.—An American contemporary says that Prof. Temistocle Calzecchi, of the Liceo of Fermo, claims priority over Branly himself in the discovery and employment of coherers. As long ago as July, 1884, he says he made known the characteristic properties of metallic filings in the pages of the *Nuovo Cimento*. Subsequently, in conjunction with Prof. Auerbach, of Breslau, he employed his coherer for various practical purposes, but not, apparently, for wireless telegraphy. One of his papers was entitled, "On a new form which may be given to the Microseismic Indicator." He says in it: "A slight tremor communicated to the table holding the tube, a small tuning fork standing on it and vibrating, and sometimes a note sung are sufficient to deprive the filings of their conductivity."

"Nothing New Under the Sun."—The *New York World* of December 26th, says the *Electrical Engineer* of New York, prints a story with an "illustration" of Mr. Nikola Tesla's latest work, consisting of an apparatus for generating steam by means of the heat of the sun's rays when available. According to the *World*, Mr. Tesla is planning to build an immense plant on Long Island as soon as his model is perfected. In the centre of a large room with a glass roof will be placed a huge cylinder of thick glass. This will repose on a bed of asbestos. A system of mirrors will reflect the rays of the sun into the glass cylinder full of chemically-treated water, and thus generate steam which will be led to a steam engine. Mr. Tesla proposes to give his invention free to the world when it is worked out. Whether the world, assuming it is not the *New York World*, will derive much benefit from Mr. Tesla's munificent gift remains to be seen. Probably, however, the whole affair is a huge joke, that has had its inception in the teeming brain of a *World* reporter. Still the idea credited to Mr. Tesla is not strikingly new. Twenty-five years ago, and the very recollection is convincing that age groweth upon us, we assisted in experiments at the works of the British Telegraph Manufactory, which showed the heating effect obtainable from the reflected rays of an arc lamp. By means of parabolic reflectors we were able to anticipate electric cooking, for not only was water boiled but we succeeded in cooking chops, the apparatus being almost identical with that attributed to Tesla:—A copper boiler in the shape of a tube, a glass casing, covering but separated from the boiler by an air space, and the parabolic reflector for concentrating and focussing the rays of the sun or an electric arc. In Algeria experiments on a bigger scale were attempted, and steam was actually raised in a boiler which was subject to the reflected rays of the sun. Moreover, Sir Henry Bessemer has for years, by means of a specially-constructed glass house and reflectors, demonstrated the extraordinary heating effect of the sun's rays.

Röntgen Rays.—Before the Röntgen Society, on Tuesday evening, at 11, Chandos Street, under the presidency of Prof. Silvanus Thompson, a paper was read by Mr. W. Webster, F.C.S., on "Practical Work with the X Rays." He first dealt, says the *Chronicle*, with the question of the best apparatus to use, and pointed out the value of primary batteries. The best coils were of English manufacture, and he used a 20-inch coil, which gave a 20-inch spark, and which, with a pneumatic attachment, worked admirably. Mr. Webster then pointed out how much had been done by Sir William Crookes and Mr. Jackson, and remarked that Dr. Röntgen had merely put the finishing touch to their discoveries. He showed the tube which had been made by Mr. Jackson in 1894, with which he had demonstrated that wood and other materials were pervious to certain rays. He had found an improvement to prevent the spark from passing round the bowl of the tube, and thus lessening the danger of perforation. By heating the tube and starting with a small spark he was able gradually to produce the effect he wished, and had thereby saved the lives of many tubes. The bulb of the tube should not be very large, as the larger it was the more difficult the tube was to condition, and the greater were the number of accidents. An aluminium cover for the cathode tube was an advantage, and a protector of sheet-iron was useful for saving the hands from the effect of the rays. The effect of the rays varied very much with different subjects. In the case of one patient, whose head was photographed, a patch of his hair first turned grey and then came out, and he was not grateful to the rays; however, the hair had grown again afterwards of the original colour. In other cases, however, the pain in the injured or diseased part had entirely ceased after five or six minutes' exposure to the rays. Anæmic subjects were the best to photograph, while gouty subjects were particularly difficult. To produce good negatives, considerable experience in photographic development was necessary, especially in the production of cloud negatives.

Electricity and Fires.—A *Pall Mall Gazette* representative has been interviewing Dr. John Hopkinson to ascertain his opinions as to whether greater immunity from fire might be expected from a wider use of electricity as an illuminant. While admitting at the outset that many fires had been due in the past to electrical causes—commonly through the wires overheating and igniting woodwork—Dr. Hopkinson said that in properly wired premises there was absolutely no danger. The fuse had always been used, but not always with sufficient care. The fuse was an expedient for safety—a piece of lead interposed in a circuit, that melted before the wires became red hot, and thus broke the circuit. No one, he continued, knew how to get security in the use of gas. A careless person, leaving the gas on, filled the room, and an explosion followed, with consequences generally more disastrous than in fires electrically caused, which, of course, were cases of simple ignition. Then, too, gas supplied combustible material to fires when once they had started.

The Electrical Engineer Volunteers.—A circular is shortly to be issued, says the *Daily Mail*, respecting this volunteer corps, to electrical engineers in the country. The corps is, for the present, limited to 240. Its duties are principally to carry out operations with the search light. The members will be exempt, in a large measure, from ordinary drill, but will have to go for eight days' continuous training during the year at the various naval bases. The uniform is that of the submarine miners. Lord Kelvin is the honorary colonel and Dr. Hopkinson is major and commanding officer. Applications are arriving daily, and it is said that in some electrical works near London 100 men have volunteered for service. For the moment, and until some details as to headquarters, and the like have been settled, the commanding officer is not inviting recruits.

A New Metal.—According to a daily paper, Mr. Thomas A. Edison announces a discovery of a new metal, which, admixed with iron, renders cast-iron as tough and strong as wrought-iron. Mr. Edison declines to go into the details now. It is stated that he is about to begin a series of exhaustive experiments to determine the conditions most favourable to obtaining the best results.

Marriage of Mr. Philip Dawson.—The little parish church of Fittleworth was overcrowded on Wednesday last on the marriage of Mr. Philip Dawson, M.Inst E.E., and Assoc.M.Inst.C.E., with Miss Lucy Hume Simpson, daughter of the Vicar, Prebendary A. B. Simpson. To do honour to the ceremony, the village turned out to a man, and the church and railway station were handsomely decorated with flowers. Mr. Dawson had taken complete possession of the picturesque old Swan Inn, and there entertained a large party of his friends on Tuesday evening. Among his guests were Messrs. F. H. Webb, Conrad Cooke, R. W. Blackwell, H. F. Parshall, O. H. Baldwin, A. K. Baylor, and I. E. Winslow, representing the electrical fraternity. The presents were many and handsome, the most noticeable being a magnificent silver punch bowl and goblets presented by Mr. R. W. Blackwell's staff. Immediately after the ceremony, Mr. and Mrs. Dawson left for the Continent, where they will spend their honeymoon.

Obituary.—We regret to record the death of Sir Charles Hutton Gregory, who passed away on Monday last at his residence, Duchess Street, Portland Place. He was a son of Mr. Olinthus G. Gregory, a professor of mathematics at the Military Academy at Woolwich, and was born in 1817. He was President of the Institution of Civil Engineers in 1868, and occupied the post for two years. Sir Charles served in many public capacities connected with his profession. He was employed abroad as consulting engineer for railways to the colonies of Ceylon, Cape of Good Hope, Trinidad, and some of the Malay territories. He was created K.C.M.G. in 1883.

We also regret to observe that Mr. John Farquharson, late electrician to the Admiralty, died at Woodland Cottage, Acton, some days ago. He was in his 76th year.

Lectures.—Mr. James Swinburne commenced a course of lectures upon "Dynamo and Transformer Construction," at the Electrical Standardising, Testing, and Training Institution yesterday (Thursday).

Appointment Vacant.—The West Ham Council want a chief assistant engineer in the borough electrical engineer's department at £130 per annum. See our "Official Notices" for particulars.

NEW COMPANIES REGISTERED.

International Lighting Association, Limited (3,720).—Registered at Edinburgh, January 5th, with capital £100,000 in £1 shares, to acquire as a going concern the business now or lately carried on by the Colonial Lighting Syndicate, Limited, and to carry on in any part of the world the business of an electric light company in all its branches. The subscribers (with one share each) are:—J. Hepworth, 4, Priestfield Road, Edinburgh, civil engineer; W. Haldane, 59, Queen Street, Edinburgh, W.S.; T. Laird, 46, Castle Street, Edinburgh, chartered accountant; F. Haldane, The Lodge, Ratho, Edinburgh, W.S.; T. Law, Woodlands, Duddingston, gentleman; W. Mackenzie, 12, Alva Street, Edinburgh, advocate; J. Pattullo, 28, Frederick Street, Edinburgh, S.S.C. The first directors are: J. Hepworth, W. Haldane, J. Dempster, Newton Heath, Manchester; W. Cowan, London. Qualification, £500. Registered by J. Pattullo, 28, Frederick Street, Edinburgh. Registered office, 28, Frederick Street.

Synchronome Syndicate, Limited (55,474).—Registered December 31st, with capital £15,000 in £1 shares, to acquire the business carried on at Westminster as "The Synchronome Syndicate," to acquire certain patents relating to electric clocks, to adopt an agreement with F. H. Jones and G. B. Bowell, and to manufacture, sell, and deal in electric clocks, electric synchronisers, dials, and other electric plant. The subscribers (with one share each) are:—A. M. Fletcher, 85, Gracechurch Street, E.C., gentleman; M. Robertson, 85, Gracechurch Street, E.C., secretary; W. B. Butler, 2, Portsea Place, Hyde Park, W., gentleman; J. M. Macnerran, 2, East India Avenue, E.C., gentleman; W. Murray, Elm Lodge, Ditton Hill, gentleman; F. B. Grey, Monk's Gate, Horsham, gentleman; C. S. Hobson, 55, Cornhill, E.C., stockbroker. The number of directors is not to be less than three nor more than six. The first are F. E. D. Acland, W. Murray, and J. M. Macnerran; qualification, £100; remuneration, £50 each per annum and a share in the profits. Registered by Ashurst & Co., 17, Throgmorton Avenue, E.C.

Heswall Electric Light Company, Limited (55,482).—Registered January 1st with capital £1,500, in £1 shares, to carry on at Heswall, Cheshire, or elsewhere, the business of electricians, mechanical engineers, suppliers of electricity, and electric apparatus manufacturers. The subscribers (with one share each) are:—C. MacIver, Beechfield, Heswall, Cheshire, gentleman; L. J. Dobie, Moorland House, Heswall, Cheshire, schoolmaster; T. Brocklebank, The Rescote, Heswall, Cheshire, gentleman; C. B. Reyds, 35, Church Street, Birkenhead, cotton broker; R. E. R. Brocklebank, Poulton Reyde, Bebington, coal merchant; R Brancker, Sunnyside, Heswall, Cheshire, coal merchant; Mrs. E. M. Brancker, Sunnyside, Heswall, Cheshire. The number of directors is not to be more than four; the first are T. Brocklebank, L. Dobie, C. MacIver and R. Brancker. Registered by Norris & Co., 20, Bedford Row, W.C.

Northern Counties Electric and Motor Company, Limited (55,551).—Registered January 7th with capital £10,000, in £1 shares, to purchase, manufacture, sell, hire, let on hire, or otherwise deal in, electric and other motors, cycles, carts, cabs, waggons, vehicles, ships, boats, launches and carriages. The subscribers (with one share each) are:—S. Jackson, Tanfield Chambers, Bradford, architect; W. Beverley, 16, Piccadilly, Bradford, barrister; G Scarborough, Halifax, manufacturer; G. Buckley, Tower Chambers, Halifax, architect; J. Pollard, Halifax, chemist; W. Hanson, Halifax, cotton spinner; W. Asquith, Birks Hall, Halifax, engineer. The number of directors is not to be less than two, or more than seven; the subscribers are to appoint the first. Qualification, £100; remuneration as fixed by the company. Registered by C. Doubble, 14, Serjeant's Inn, E.C.

OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

Electro-Chemical Company, Limited (40,496).—This company's return, made up to December 3rd, shows that the capital of £200,000 in £5 shares (26,000 preference) has been fully subscribed. 14,000 ordinary and 5,000 preference are considered as paid. £5 per share has been called on 12,710, and £4 per share on the others, and £99,834 has been paid.

Newton Electrical Works, Limited (48,936).—This company's annual return was filed on September 7th. The capital is £30,000 in £10 shares. 2,100 have been taken up, 1,400 are considered as paid, and £7,000 has been received.

Wireless Telegraph and Signal Company, Limited (53,403).—This company's statutory return, made up to December 2nd, was filed on December 10th. The capital is £100,000 in £1 shares, of which 95,015 have been taken up. 60,000 are considered as paid, and £35,015 has been received.

Venezuela Telephone and Electrical Appliances Company, Limited (31,305).—This company's return was filed on December 4th. The capital is £85,000 in 70,000 shares of £1 each, and 1,500 shares of £10 each. All the £1 and 360 £10 shares have been taken up, and 56,506 £1 shares are considered as paid. The full amount has been called on the others, and £17,094 has been received.

Electric Welding Company, Limited (31,364).—This company's return, made up to December 14th, was filed on December 24th last. The capital is £460,000 in £10 shares (1,000 founders'); 24,780 ordinary and 953 founders' shares have been taken up, and 8,333 ordinary are considered as paid. The full amount has been called on the founders' and £6 per share on the remaining ordinary, and £119,092 has been received, leaving £54,908 to be brought in.

New Phonophore Telephone Company, Limited (44,654).—This company's return was filed on November 9th, when 5,111 ordinary and 1,000 founders' shares were taken up out of a capital of £10,000 in £1 shares. The founders' shares are considered as paid, and 10s. per share has been called and paid on the others.

National Electric Free Wiring Company, Limited (53,364).—This company's statutory return, made up to November 17th, has just been filed; 100,000 shares are to be taken up out of a capital of £250,000, in £1 shares, and 5s. per share (£25,000) has been paid.

Electrical Undertakings, Limited (52,917).—This company's statutory return was filed December 16th, when a capital of £10,000 in £1 shares was fully taken up. 7,493 shares are considered as paid, and £2,507 has been paid on the others.

Electrical Pioneer Syndicate, Limited (52,917).—This company's statutory return was filed October 15th, when 42 shares were taken up out of a capital of £10,000 in £50 shares, £25 has been called, and £1,000 received, leaving £75 unpaid; £25 has been received in advance.

CITY NOTES.

Oldham, Ashton and Hyde Electric Tramway Company, Limited.

There has been before the public this week a prospectus of the above company, which has a nominal share capital of £80,000, offering the whole of that sum for subscription in the form of 4,000 5 per cent. £10 cumulative preference and 4,000 ordinary shares of £10 each. There will also be an issue of £40,000 debentures as occasion requires. The company will construct and work an electric tramway, eight miles in length, from the boundary of Oldham through Ashton-under-Lyne, Audenshaw and Denton to Hyde, as authorised by a provisional order granted to the British Electric Traction (Pioneer) Company in 1896. The prospectus gives a few remarks on the advantages of electric traction, and particulars and map of the districts to be served by the tramways. The electrical energy will be supplied by the Corporation of Ashton under an agreement made by the British Electric Traction (Pioneer) Company. It is estimated that when the tramways are in full operation the net profit will be about £10,000 per annum. The dividend on the preference shares for the first three years has been secured by the deposit of cash or securities with the Electric and General Investment Company. It is estimated that the line will be in full working order within that period. The permanent way is being laid by Messrs. Dick, Kerr & Co., and the whole of the electrical equipment and rolling stock will be provided by the British Thomson-Houston Company. The total payable under the various contracts is £105,362. The list of applications opened on Monday last and closed on Wednesday. The directors are Mr. Emile Garcke (chairman), and Messrs. Atherley Jones, Q.C., M.P.; Alderman Thomas Higginbottom, J.P.; A. R. Monks, Alderman Robert Whittaker, J.P. Messrs. H. F. Parshall and Stephen Sellon are the engineers. The registered offices are Donington House, Norfold Street, Strand, and Mr. H. S. Hodgson is secretary.

The Sussmann Electric Miners' Lamp Company, Limited.

An extraordinary general meeting of the shareholders of this company was held yesterday at the Cannon Street Hotel, Mr. A. Castle presiding.

The Chairman explained that the sole object of the meeting was to propose resolutions for altering articles in certain particulars. The board promised at the annual meeting that they would consider the advisability of reducing their number and the fees paid to them. Having given the question careful attention, they had decided to ask the shareholders to alter the articles, so that instead of the board consisting of five as heretofore, and the remuneration £200 each, its future strength would be three at a remuneration of £100 each. He then moved the necessary resolutions, which were seconded by Mr. J. D. Wright, and carried.

The Direct United States Cable Company, Limited.—The board have resolved upon the payment of an interim dividend of 3s. per share, free of income tax, being at the rate of 3 per cent. per annum, for the quarter ending December 31st, 1897, such dividend to be payable on and after 29th inst., setting aside £12,000 to reserve fund account, and carrying forward a balance of £4,090 2s. 2d. And notice is also given that the transfer books of this company will be closed from January 11th to the 25th (both days inclusive).

The Westminster Electric Supply Corporation, Limited.—To provide for the redemption of the present 5 per cent. and 4½ per cent. first mortgage debenture of the corporation, and to meet the necessary capital expenditure, owing to the continued increase of the company's business, this company has resolved to issue an amount of £200,000 first mortgage debentures, carrying interest at the rate of 3½ per cent. per annum.

The House-to-House Electric Light Supply Company, Limited.—An extraordinary general meeting of this company was held at Winchester House on Wednesday, when the resolution which was passed at the extraordinary general meeting of the company, held on December 28th, 1897, and reported in our issue of December 31st, was submitted and confirmed as a special resolution.

Direct West India Cable Company.—The 4½ per cent. debentures can now be obtained in exchange for script. Cheques for interest on instalments to December 31st will be issued with the debentures. The laying of the company's cable was began last Friday from Bermuda. Jamaica is expected to be reached about 20th.

River Plate Electric Light and Traction Company.—A meeting of the above company was held on Wednesday at the offices, 78, Coleman Street, but a representative of the Electrical Review was informed that the meeting was private.

TRAFFIC RECEIPTS.

The City and South London Railway Company. The receipts for the week ending January 9th, 1898, were £1,124; week ending January 10th, 1897, £1,111; increase, £13; total receipts for half-year, 1898, £2,174; corresponding period, 1897, £2,188; decrease, £14.

The Cuba Submarine Telegraph Company. The receipts for the month of September were £2,684, as compared with £3,966 in the corresponding month of last year.

The Great Northern Telegraph Company. The receipts in December, 1897, were £25,000; January 1st to December 31st, 1897, £277,800; corresponding months, 1896, £285,800; corresponding months, 1895, £312,400.

The Liverpool Overhead Railway Company. The receipts for the week ending January 9th, 1898, amounted to £1,438; corresponding week last year, £1,265; increase, £173.

The Western and Brazilian Telegraph Company, Limited. The receipts for the week ending January 7th, 1898, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £2,405.

THE APPLICATION OF VECTOR ALGEBRA TO ALTERNATING CURRENTS.

By W. G. RHODES, M.Sc., Royal Technical Institute, Salford.

(*Continued from page* 25.)

Circuits Containing Resistance and Capacity Only.

14. Suppose that a potential difference e is applied between the terminals of a circuit having a resistance r and a capacity C in series. If i is the current flowing through the circuit, and p has the usual meaning, the potential difference must have a component $r\,i$ in the direction of the current to drive the current against the ohmic resistance of the circuit, and a component $-\frac{k\,i}{p\,\text{C}}$ lagging a right angle behind the current, to balance the capacity E.M.F. $+\frac{k\,i}{p\,\text{C}}$ (see proposition 3, Section 9). We therefore have the vector equation

$$r\,i - \frac{k\,i}{p\,\text{C}} = e. \qquad (6)$$

This equation is represented graphically in Fig. 8, in which O P is the vector $r\,i$, O Q[1] the vector representing the E.M.F. due to capacity, P Q the vector representing the E.M.F. necessary to balance that due to capacity, and O Q that representing the applied potential difference.

The magnitude of e is by Section 3 given by

$$e = \sqrt{r^2 + \frac{1}{p^2\,\text{C}^2}}\,.\,i.$$

Equation (6) may be changed into a current vector equation, thus—

$$i = \frac{e}{r - \frac{k}{p\,\text{C}}} = \frac{e\left(r + \frac{k}{p\,\text{C}}\right)}{r^2 + \frac{1}{p^2\,\text{C}^2}}$$

or

$$i = \frac{r}{r^2 + \frac{1}{p^2\,\text{C}^2}}\,.\,e + \frac{\frac{1}{p\,\text{C}}}{r^2 + \frac{1}{p^2\,\text{C}^2}}\,.\,k\,e. \qquad (7)$$

This is the current vector equation, and is represented in fig. 9, which shows the components of the current along and at right angles to the potential difference, e.

Either the equations (6) and (7), or figs. 7 and 8 show that the current leads before the potential difference by an angle θ where

$$\tan\theta = \frac{1}{p\,\text{C}\,r}. \qquad (8)$$

Circuits containing Resistance, Self-Induction, and Capacity.

15. Consider a circuit consisting of a coil of wire, having a resistance r, and self-induction L, placed in series with a condenser of capacity C. Let an alternating potential difference e, of frequency n, be impressed between the extreme terminals of the circuit, causing an alternating current i to flow through it, and let $p = 2\,\pi\,n$.

The potential difference must have a component, $r\,i$, in the direction of the current, to drive the current against the ohmic resistance r, a component $k\,p\,\text{L}\,i$, to balance the E.M.F., $-k\,p\,\text{L}\,i$, of self-induction, and a component $-\frac{k\,i}{p\,\text{C}}$, to balance the E.M.F. $\frac{+k\,i}{p\,\text{C}}$, due to capacity. We therefore have the vector equation of E.M.F.s,

$$r\,i + k\,p\,\text{L}\,i - \frac{k\,i}{p\,\text{C}} = e,$$

or

$$r\,i + k\left(p\,\text{L} - \frac{1}{p\,\text{C}}\right)i = e. \qquad (9)$$

This equation is graphically represented in fig. 10, where O P is the vector $r\,i$, O L the vector $-k\,p\,\text{L}\,i$, O C the vector $\frac{k\,i}{p\,\text{C}}$, P Q the vector $-(\text{OL} + \text{OC})$, and O Q the vector e.

If O L is greater than O C, the current lags behind the potential difference by an angle θ, where

$$\tan\theta = \frac{\left(p\,\text{L} - \frac{1}{p\,\text{C}}\right)}{r}.$$

If O C is greater than O L, the current leads before e by an angle given by

$$\tan\theta = \frac{\dfrac{1}{p\,\mathrm{C}} - p\,\mathrm{L}}{r}.$$

If O L equals O C, that is, if

$$p\,\mathrm{L} = \frac{1}{p\,\mathrm{C}},$$

the current and potential difference are in phase.

16. We shall denote the quantity $p\,\mathrm{L} - \dfrac{1}{p\,\mathrm{C}}$ by the letter s, and call it the *reactance* of the circuit. Equation (9) then becomes

$$r\,i + k\,s\,i = e. \tag{10}$$

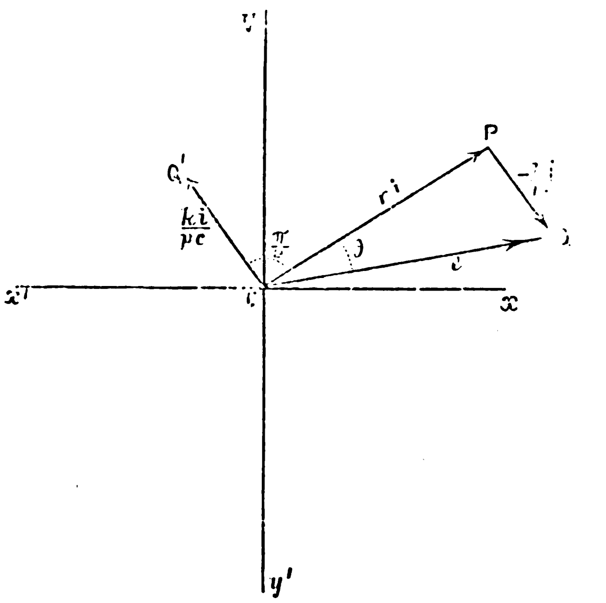

Fig. 8.

From this we get

$$i = \frac{e}{r + k\,s}$$

$$= \frac{e\,(r - k\,s)}{r^2 + s^2}$$

that is
$$i = \frac{r}{r^2 + s^2}\,.\,e - \frac{s}{r^2 + s^2}\,.\,k\,e. \tag{11}$$

Equations (10) and (11) are equations (1) and (3) extended to the case in which the circuit contains both self-induction and capacity, the former being an equation of E.M.Fs. and the latter an equation of currents.

It should be noticed that the magnitude of e is given by equation (10) to be

$$e = \sqrt{r^2 + s^2}\,.\,i,$$

whence
$$i = \frac{e}{\sqrt{r^2 + s^2}} \tag{12}$$

the quantity $\sqrt{r^2 + s^2}$ being the impedance of the circuit.

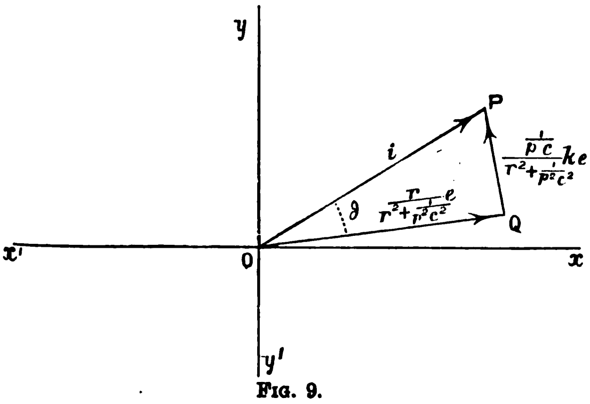

Fig. 9.

Combination of Circuits.

17. (*a*) *Series Circuits.*—Suppose that m reactive circuits are connected in series, and that a potential difference e is applied between the extreme terminals of the combination. We propose to determine the equivalent resistance, R, and the equivalent reactance, S, of the combination.

Let the resistance of the circuits be respectively $r_1, r_2, r_3, \ldots . r_m$, and their respective reactances $s_1, s_2, s_3, \ldots . s_m$; and let the potential differences between the terminals of the respective circuits be $e_1, e_2, e_3, \ldots . e_m$, and i the current common to all the circuits.

We then have, by applying equation (10) to each circuit in succession,

$$r_1\,i + k\,s_1\,i = e_1$$
$$r_2\,i + k\,s_2\,i = e_2$$
$$r_3\,i + k\,s_3\,i = e_3$$
$$\ldots\ldots\ldots$$
$$\ldots\ldots\ldots$$
$$r_m\,i + k\,s_m\,i = e_m.$$

Therefore
$$e = e_1 + e_2 + e_3 + \ldots . + e_m$$
$$= (r_1 + r_2 + r_3 + \ldots . + r_m)\,i +$$
$$k\,(s_1 + s_2 + s_3 + \ldots . s_m)\,i. \tag{13}$$

But, applying equation (10) to the combination, we have

$$e = \mathrm{R}\,i + k\,\mathrm{S}\,i \tag{14}$$

Thus, by comparison of (13) and (14), we see that

$$\left.\begin{aligned} \mathrm{R} &= r_1 + r_2 + r_3 + \ldots . + r_m \\ \text{and}\quad \mathrm{S} &= s_1 + s_2 + s_3 + \ldots . + s_m \end{aligned}\right\} \tag{15}$$

that is, the resistance and reactance of the series combination are, respectively, the sums (algebraic) of the resistances and reactances of the constituent circuits.

18. (*b*) *Parallel Circuits.*—Suppose that m reactive circuits are connected in parallel, and that is required to determine the equivalent resistance and reactance of the combination. It is better to subdivide this problem into two distinct cases, according as mutual induction is not, or is, taken into consideration.

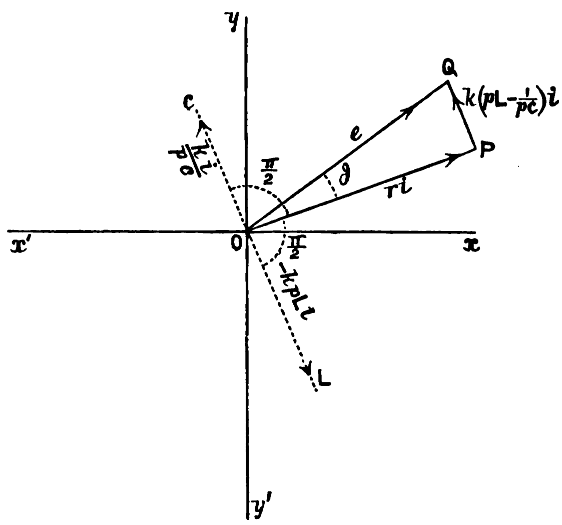

Fig. 10.

19. *Case I.—Mutual Induction Neglected.*—Let the resistances and reactances of the individual circuits be $r_1, r_2 \ldots . r_m$ respectively, and $s_1, s_2 \ldots . s_m$ respectively; and let the potential difference common to each circuit be e — a vector, the currents in the respective circuits being $i_1, i_2 \ldots . i_m$ — all vectors.

Then applying equation (11) to each circuit in succession we have the vector current equations

$$\left.\begin{aligned} i_1 &= \frac{r_1}{r_1^2 + s_1^2}\,.\,e - \frac{s_1}{r_1^2 + s_1^2}\,.\,k\,e \\ i_2 &= \frac{r_2}{r_2^2 + s_2^2}\,.\,e - \frac{s_2}{r_2^2 + s_2^2}\,.\,k\,e \\ &\ldots\ldots\ldots \\ &\ldots\ldots\ldots \\ i_m &= \frac{r_m}{r_m^2 + s_m^2} - \frac{s_m}{r_m^2 + s_m^2}\,.\,k\,e \end{aligned}\right\} \tag{16}$$

But the current i in the main circuit is the *vector* sum of the currents in the several branches of the parallel circuit, therefore we have the vector equation

$$i = i_1 + i_2 + \ldots . + i_m$$
$$= \left(\frac{r_1}{r_1^2 + s_1^2} + \frac{r_2}{r_2^2 + s_2^2} + \ldots . + \frac{r_m}{r_m^2 + s_m^2}\right) e$$
$$- \left(\frac{s_1}{r_1^2 + s_1^2} + \frac{s_2}{r_2^2 + s_2^2} + \ldots . + \frac{s_m}{r_m^2 + s_m^2}\right) k\,e$$

Or, writing A for

$$\left.\begin{aligned} &\frac{r_1}{r_1^2 + s_1^2} + \frac{r_2}{r_2^2 + s_2^2} + \ldots . + \frac{r_m}{r_m^2 + s_m^2} \\ \text{and B for}\quad &\frac{s_1}{r_1^2 + s_1^2} + \frac{s_2}{r_2^2 + s_2^2} + \ldots . + \frac{s_m}{r_m^2 + s_m^2} \end{aligned}\right\} \tag{17}$$

we get

$$i = \mathrm{A}\,e - k\,\mathrm{B}\,e$$
$$= (\mathrm{A} - k\,\mathrm{B})\,e$$
$$= \frac{(\mathrm{A}^2 + \mathrm{B}^2)\,e}{\mathrm{A} + k\,\mathrm{B}}$$
$$= \frac{e}{\dfrac{\mathrm{A}}{\mathrm{A}^2 + \mathrm{B}^2} + k\,\dfrac{\mathrm{B}}{\mathrm{A}^2 + \mathrm{B}^2}} \qquad (18)$$

and by comparison of this with the equation for the combination,

$$i = \frac{e}{\mathrm{R} + k\,\mathrm{S}} \qquad (19)$$

We see that the equivalent resistance and equivalent are repectively given by

$$\left.\begin{aligned} \mathrm{R} &= \frac{\mathrm{A}}{\mathrm{A}^2 + \mathrm{B}^2} \\ \text{and} \quad \mathrm{S} &= \frac{\mathrm{B}}{\mathrm{A}^2 + \mathrm{B}^2} \end{aligned}\right\} \qquad (20)$$

Also, the equivalent impedance, I, of the multiple circuit is given by

$$\mathrm{I} = \sqrt{\mathrm{R}^2 + \mathrm{S}^2}$$
$$= \frac{1}{\sqrt{\mathrm{A}^2 + \mathrm{B}^2}} \qquad (21)$$

where A and B are defined by (17).

20. An interesting particular case of the above is that in which the parallel arrangement consists of two circuits, one of which contains a resistance, r, and a self-induction, L, only, while the other contains a capacity, C, only.

In this case $r_1 = r$; $s_1 = p\,\mathrm{L}$; $r_2 = 0$; $s_2 = -\dfrac{1}{p\,\mathrm{C}}$; so that

$$\mathrm{R} = \frac{r}{r^2 + p^2\,\mathrm{L}^2}; \quad \mathrm{S} = \frac{p\,\mathrm{L}}{r^2 + p^2\,\mathrm{L}^2} - p\,\mathrm{C}.$$

Also if i_1 and i_2 are the currents in the two branches

$$i_1 = \frac{e}{\sqrt{r^2 + p^2\,\mathrm{L}^2}}; \quad i_2 = p\,\mathrm{C}\,e,$$

therefore

$$\frac{i_2}{i_1} = p\,\mathrm{C}\,\sqrt{r^2 + p^2\,\mathrm{L}^2},$$

which shows that for high frequencies the greater part of the current passes through the condenser circuit.

Also if i is the main current

$$i = \frac{e}{\sqrt{\mathrm{R}^2 + \mathrm{S}^2}}$$
$$= \frac{e}{\sqrt{\left\{\dfrac{r^2}{(r^2 + p^2\,\mathrm{L}^2)^2} + \left(\dfrac{p\,\mathrm{L}}{r^2 + p^2\,\mathrm{L}^2} - p\,\mathrm{C}\right)^2\right\}}}$$
$$= \frac{e\,(r^2 + p^2\,\mathrm{L}^2)}{\sqrt{\{r^2 + p^2\,(\mathrm{L} - \mathrm{C}\,r^2 + p^2\,\mathrm{L}^2)^2\}}}$$

21. *Case II—Mutual Induction taken into Consideration.*—This case is somewhat complicated since, if we consider any particular branch of the parallel circuit, the E.M.F. which drives the current against its ohmic resistance is the resultant of $m + 1$ distinct E.M.Fs.; viz., the applied potential difference, the E.M.F. due to the reactance of the circuit and the E.M.Fs. due to the mutual inductions between it and the remaining $m - 1$ branch circuits.

Let the mutual inductions of the several pairs of circuits be M_{12}, M_{13}, ... M_{pq} ...., where the suffixes denote the two circuits to which the M refers. Since the mutual induction between two circuits is a reciprocal relation, $\mathrm{M}_{pq} = \mathrm{M}_{qp}$, where p and q are any different integers from 0 to m. Let the rest of the notation be as in Case I. Then considering the circuit 1, the applied potential difference must furnish $m + 1$ components, one equal to $r_1\,i_1$, to drive the current against the ohmic resistance of the circuit; a second given by $k\,p\,s_1\,i_1$, to balance the reactive E.M.F. of the circuit; a third given by $k\,p\,\mathrm{M}_{12}\,i_2$ to balance the E.M.F. due to the mutual induction of the circuits 1 and 2 (see Proposition 2); a fourth given by $k\,p\,\mathrm{M}_{13}\,i_3$ to balance the E.M.F. due to the mutual induction of the circuits 1 and 3, and so on.

Thus the vector equation of E.M.Fs. in circuit 1 is

$$\left.\begin{aligned}
&r_1\,i_1 + k\,s_1\,i_1 + k\,p\,\mathrm{M}_{12}\,i_2 + k\,p\,\mathrm{M}_{13}\,i_3 + \ldots + k\,p\,\mathrm{M}_{1m}\,i_m = e \\
&\text{Similarly for circuit 2:} \\
&k\,p\,\mathrm{M}_{21}\,i_1 + r_2\,i_2 + k\,s_2\,i_2 + k\,p\,\mathrm{M}_{23}\,i_3 + \ldots + k\,p\,\mathrm{M}_{2m}\,i_m = e \\
&\text{Similarly for circuit 3:} \\
&k\,p\,\mathrm{M}_{31}\,i_1 + k\,p\,\mathrm{M}_{32}\,i_2 + r_3\,i_3 + k\,s_3\,i_3 + \ldots + k\,p\,\mathrm{M}_{3m}\,i_m = e \\
&\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot \\
&\text{Similarly for circuit } m: \\
&k\,p\,\mathrm{M}_{m1}\,i_1 + k\,p\,\mathrm{M}_{m2}\,i_2 + k\,p\,\mathrm{M}_{m3}\,i_3 + \ldots + r_m\,i_m + k\,s_m\,i_m = e
\end{aligned}\right\} \qquad (22)$$

These are m simultaneous simple equations from which to determine the currents i_1, i_2, i_3 .... i_m, whence, by substitution, the current, i, in the main circuit can be obtained from the vector equation

$$i = i_1 + i_2 + i_3 + \ldots + i_m.$$

In this way we shall arrive, in any particular case, at an equation of the form

$$i = \mathrm{P}\,e + k\,\mathrm{Q}\,e,$$

where P and Q are independent of k. Having obtained this equation the equivalent resistances and reactances can be found in the usual manner.

As the solution of the general case is too complicated for the present paper, we will illustrate the process by the simple example of two mutually inductive circuits.

22. In this case the vector equations to be solved are

$$\left.\begin{aligned}
(r_1 + k\,s_1)\,i_1 + k\,p\,\mathrm{M}_{12}\,i_2 &= e \\
k\,p\,\mathrm{M}_{21}\,i_1 + (r_2 + k\,s_2)\,i_2 &= e \\
\text{and} \qquad i &= i_1 + i_2
\end{aligned}\right\} \qquad (23)$$

whence, on putting $\mathrm{M}_{12} = \mathrm{M}_{21} = \mathrm{M}$

$$\left.\begin{aligned}
\{(r_1\,r_2 - s_1\,s_2) + k\,(r_1\,s_2 + r_2\,s_1)\}\,i_1 &= \{r_2 + k\,(s_2 - p\,\mathrm{M})\}\,e \\
\text{and} \qquad & \\
\{(r_1\,r_2 - s_1\,s_2) + k\,(r_1\,s_2 + r_2\,s_1)\}\,i_2 &= \{r_1 + k\,(s_1 - p\,\mathrm{M})\}\,e
\end{aligned}\right\}$$

which by multiplying both sides of the equations by $(r_1\,r_2 - s_1\,s_2) - k\,(r_1\,s_2 + r_2\,s_1)$, and simplifying, may be written

$$\left.\begin{aligned}
(r_1^2 + s_1^2)\,(r_2^2 + s_2^2)\,i_1 = [&r_1\,(r_2^2 + s_2^2) - p\,\mathrm{M}\,(r_1\,s_2 + r_2\,s_1) \\
&- k\,\{s_1\,(r_2^2 + s_2^2) + p\,\mathrm{M}\,(r_1\,r_2 - s_1\,s_2)\}]\,e \\
\text{and} \qquad & \\
(r_1^2 + s_1^2)\,(r_2^2 + s_2^2)\,i_2 = [&r_2\,(r_1^2 + s_1^2) - p\,\mathrm{M}\,(r_1\,s_2 + r_2\,s_1) \\
&- k\,\{s_2\,(r_1^2 + s_1^2) + p\,\mathrm{M}\,(r_1\,r_2 - s_1\,s_2)\}]\,e
\end{aligned}\right\} \qquad (24)$$

These are the vector current equations giving the components of i_1 and i_2 along and at right angles to e. By addition we have

$$\begin{aligned}
(r_1^2 + s_1^2)\,(r_2^2 + s_2^2)\,i = [&r_1\,(r_2^2 + s_2^2) + r_2\,(r_1^2 + s_1^2) - 2\,p\,\mathrm{M}\,(r_1\,s_2 + r_2\,s_1) \\
&- k\,\{s_1\,(r_2^2 + s_2^2) + s_2\,(r_1^2 + s_1^2) + 2\,p\,\mathrm{M}\,(r_1\,r_2 - s_1\,s_2)\}]\,e, \qquad (25)
\end{aligned}$$

which gives the components of the main current along and at right angles to e; thus the component in phase with e is

$$\left\{\frac{r_1}{r_1^2 + s_1^2} + \frac{r_2}{r_2^2 + s_2^2} - \frac{2\,p\,\mathrm{M}\,(r_1\,s_2 + r_2\,s_1)}{(r_1^2 + s_1^2)\,(r_2^2 + s_2^2)}\right\} e,$$

and the component at right angles to e, or the wattless component, as it is called, is

$$\left\{\frac{s_1}{r_1^2 + s_1^2} + \frac{s_2}{r_2^2 + s_2^2} + \frac{2\,p\,\mathrm{M}\,(r_1\,r_2 - s_1\,s_2)}{(r_1^2 + s_1^2)\,(r_2^2 + s_2^2)}\right\} e.$$

Multiplying and dividing the right-hand side of equation (25) by D where

$$\begin{aligned}
\mathrm{D} = r_1\,(r_2^2 + s_2^2) + r_2\,(r_1^2 + s_1^2) - 2\,p\,\mathrm{M}\,(r_1\,s_2 + r_2\,s_1) + k\,\{&s_1\,(r_2^2 + s_2^2) \\
&+ s_2\,(r_1^2 + s_1^2) + 2\,p\,\mathrm{M}\,(r_1\,r_2 - s_1\,s_2)\},
\end{aligned}$$

we get, after some reductions,

$$i = \frac{\{(r_1 + r_2)^2 + (s_1 + s_2)^2 - 4\,p\,\mathrm{M}\,(s_1 + s_2) + 4\,p^2\,\mathrm{M}^2\}\,e}{\mathrm{D}}$$

which shows that the equivalent resistance, R, and reactance, S, of the parallel circuit are given by

$$\left.\begin{aligned}
\mathrm{R} &= \frac{r_1\,(r_2^2 + s_2^2) + r_2\,(r_1^2 + s_1^2) - 2\,p\,\mathrm{M}\,(r_1\,s_2 + r_2\,s_1)}{(r_1 + r_2)^2 + (s_1 + s_2)^2 - 4\,p\,\mathrm{M}\,(s_1 + s_2) + 4\,p^2\,\mathrm{M}^2} \\
\mathrm{S} &= \frac{s_1\,(r_2^2 + s_2^2) + s_2\,(r_1^2 + s_1^2) + 2\,p\,\mathrm{M}\,(r_1\,r_2 - s_1\,s_2)}{(r_1 + r_2)^2 + (s_1 + s_2)^2 - 4\,p\,\mathrm{M}\,(s_1 + s_2) + 4\,p^2\,\mathrm{M}^2}
\end{aligned}\right\} \qquad (26)$$

and the equivalent impedance, I, is given by

$$\mathrm{I} = \sqrt{\mathrm{R}^2 + \mathrm{S}^2}$$
$$= \frac{\sqrt{(r_1^2 + s_1^2)\,(r_2^2 + s_2^2)}}{\sqrt{(r_1 + r_2)^2 + (s_1 + s_2)^2 - 4\,p\,\mathrm{M}\,(s_1 + s_2) + 4\,p^2\,\mathrm{M}^2}} \qquad (27)$$

(To be continued.)

GAS PRODUCERS.

A suggestive letter appears in *Engineering* from Mr. Alleyne Reynolds dealing with the working of gas producers. Adverting to the usually accepted action in a gas producer, namely, that the entering air is first reduced to CO_2 and that this is afterwards reduced to CO in its passage upwards through the fuel, the writer argues that this assumption is incorrect. His reasons against this theory are (1) that the scaffolding of slag in producers points to the hottest zone being near the top; (2) that a strong lambent flame (the flame of carbon monoxide) will issue from a leak only a few inches above the air inlet of a blown producer; (3) that in producers, more especially those worked by a forced draught, a moderately shallow fire produces the most combustible gas. Divested of a good deal of unnecessary frilling and verbiage, the contention of Mr. Reynolds appears to be that the temperature of the first combustion of carbon to CO is sufficient to prevent further oxidation to CO_2 even in the presence of free oxygen; that, in fact, the dissociation temperature has been reached, and further oxidation can only occur as the temperature is reduced. In the upper zones of a producer the slag is fused and the dissociation temperature exists, and if there be any oxygen present when the gaseous products finally emerge on the top of the fuel, the gases will pass forward to the flues on their way to the holder, and will burn as their temperature is reduced by radiation, and the whole of the excess of oxygen will be converted to CO_2. Obviously, therefore, the amount of oxygen supplied to a producer ought to be just so much as will disappear entirely to the formation of CO, a little below the upper surface of the fuel.

If a producer be so over-blown that oxygen comes out uncombined above the fuel the gas produced will be low in CO_2, because of the temperature being high and dissociation prevailing, rich in CO and in O, and this O, which should not be present, will burn some of the CO to CO_2 as the temperature falls, and the final result will be a gas rich in CO_2. If, however, a producer be worked slowly, under-blown, CO_2 may be formed at once because the walls of the producer will radiate heat and keep the temperature below that of dissociation. There is thus a happy medium of working and of fuel depth which will secure best results, and if the views advanced be correct it ought to be arranged that the gas passages can be inspected for flame. Any flame would indicate over-blowing or too small a depth of fuel.

The theory applies of course equally to the blast furnace. If y represent the calories necessary to reduce 1 unit of the oxygen from the ore, and z be the calories absorbed by 1 unit of the oxygen for other endothermic chemical and mechanical actions, then the number of carbon units will be $\frac{12\ (y\ +\ z)}{32}$ and from this the consumption of fuel per ton of iron made can be found.

Mr. Reynolds' arguments appear reasonable and if investigation and observation proved them to be correct a step forward would be possible in the working of gas producers.

Blast furnace action certainly does not contradict the new theory. In the blast furnace the ore as it travels down the furnace is reduced by the CO formed from the fuel and CO_2 results. If the temperature be above the dissociation point no insurmountable difficulty is introduced, because it is possible, and, indeed, likely, that the CO_2 would be promptly reduced to CO by the surrounding mass of incandescent carbon. The very freeing of the oxygen from its combination with a solid would require heat, and would, therefore, reduce the temperature and render possible the formation of CO_2, which would exist as such until it got away from the zone of ore reduction. It seems impossible to produce gas entirely free from CO_2. This may be due to the mass action, as are many other chemical reactions which defy all efforts to carry them to a desired completion in the sense of an entire elimination of an undesired constituent.

COLLECTIVE BARGAINING.

Engineering makes a note that the present trade dispute has brought forward a new term, "collective bargaining," which it describes as something that workmen are believed by some people to be in vain asking from the tyrant Capital, whilst others believe it to be a dangerous Socialistic doctrine. It really amounts to the desire which exists among a large number of workmen that their wages shall be fixed by bargaining between their employer and their trade union executive, so that the man when he seeks employment, and gets it, need not himself bargain for a given wage, but will receive it exactly as a shopkeeper naturally expects and receives one penny for a penny bun. A good deal may be said on the workman's side of the matter in favour of the idea of collectivism. Workmen are often little able to look after their own interests, and if faced up with an employer of considerable strength of mind, the more simple of the workmen would often be found to be receiving less than they were really entitled to receive perhaps as first-class workmen. We believe it is largely to this feeling that they cannot face up for themselves that men have joined trades unions, and though we do not see they have any right to object to the equally collective action of employers, many of these being often quite as unable to stand their corner as the most modest of the men, we do not feel disposed to unduly blame the men for their collectivism if not carried too far as it has been.

Also in respect of the policy of the trades unions in claiming a sort of vested interest in work they have been accustomed to do, we are disposed to think that such claims are but natural. The barrister who draws his fees for three different cases coming off in three separate courts at one time has a protection against the possibly better outsider who has not a license. So the lawyer and the doctor who are all savagely protected against outsiders, and even among engineers do we not find that the growth of the professorial interest is tending to confine the very title of civil engineer to examination-tested men! The workman does but copy the example of his so-called betters, and when we see boiler makers and engine fitters fighting over who shall do this or that bit of work, it might be well to consider what sort of a row there would be if the solicitor to a railway company were to proceed to harangue the Parliamentary Committee upon the clauses of a Bill, of which every detail was at his finger's ends, and of which he knew of necessity 50 times as much as the Q.C., whose study of his brief had only begun five minutes before he entered the room, yet whose right to speak the solicitor cannot gainsay. Who of us has not seen the man who did know, biting his lips with vexation as the counsel drivelled away a case which he could not master. May we not assume an equal feeling in humbler circles. Where, however, men make a mistake is in their objections to the non-union men. Because a man is a non-unionist it does not by any means follow he is not an equally good man with the unionist. Indeed, the latest tactics in filling up the ranks of the unions has very considerably lowered the expectation of securing good men from their ranks. Collective bargaining so far has been all on one side, and when an agreement has not been come to the works of an employer have been struck against and picketted, and men seeking work have been roughly handled. The tendency of all monopolies is evil. Clients who have paid barristers large fees have often felt hurt when their counsel leaves the case to a junior in whom he has "every confidence," and some of us may have had the painful experience of suffering under the malpractice of some careless medical man against whom it is practically impossible to secure a remedy. The question is one of great difficulty, but let it not be overlooked when we condemn the action of the men in joining these unions, that to them their work and living may be as important as the work of the doctor appears to himself. There is a good deal to be said for trades unions, and for even collective bargaining, and the only way out of the difficulty that we see at present is, that the union executive should be composed of men of considerable intelligence and honest intention. In comparing the monopolies of workmen with those of professional men we omit one huge difference. The lawyer or the doctor is never found making his brother professional's life a burden to him because he does more work than other men do. But in the workshop that man who works quickly and turns out a fair day's work is made miserable by his fellows. A day's work has been reduced and reduced so steadily and for so long, that a good workman finds his hardest work in spinning out his jobs.

These details, says our contemporary, of shop work are unknown to bishops and dons and mere closet students—the *dilettanti*. To ordinary men a minimum irreducible wage implies obvious reduction of output and equally obviously in abandoning a right to reduce wages, the employer loses his principal, if not only, check upon what is euphemistically described as undue leisurelyness.

THE MIDLAND RAILWAY COMPANY'S ELECTRIC LIGHT PLANT AT LEICESTER.

The lighting plant at Leicester station is gas driven, the engines being of Crossley's high speed electric type, the larger ones equal to 50 B.H.P. on Dowson gas, and running at 200 revolutions. The cylinders are 16 inches × 21 inches. To render capable of continuous running, they have been fitted with efficient oiling arrangement, and to catch waste oil the foundations are sheeted in lead and piped to suitable receptacles. They have also been improved by the addition of counterweights upon the cranks, an addition which, we think, ought to form a portion of the original design of all gas engines, but which is omitted, we believe, because of the cheapness of the bent crank in some cases. These weights cannot but reduce the crank stresses set up by weights in the double fly-wheels which are otherwise required, but not always put in.

In case of failure of the gas apparatus, the engines are arranged for changing quickly to the use of Corporation gas, an expensive luxury, which demanded a minimum consumption of 1,500 thousand feet annually before the Corporation would connect their mains.

The gas generators are two in number, each set comprising generator and boiler of a capacity of 100 H.P. at the engines, and there are similarly duplicate coolers, hydraulic box, coke scrubber and sawdust filter. One boiler, however, will provide steam for two generators. These have a diameter of 3 feet inside the lining, but the grates are only 30 inches diameter (a contemporary's figures are a little dubious at this point, it not being clear whether areas or diameters is intended, but we assume diameters as the more probable).

The generators have fire-bars, as usual, we believe, in Dowson plant, and they consume anthracite coal, and obtain the best gas when using small coal, the quality of the gas being 25 per cent. better in power production per generator as well as more even, while the small fuel is cheaper, and the generator requires less time to start, good gas coming over in 10 minutes. With large coal some of the air blown in comes over unaltered. This proves that the fuel depth in a generator, as in a boiler furnace, must vary with the size of the fuel.

In the first half-year's work to December, 1895, the cost per unit was 3·30d., and 4·6 lbs. of coal were consumed for each B.T unit developed. During the next half-year the cost was 3·09d., and the consumption 3·66 lbs. For the first half of last year the figures were respectively 2·8d. and 3·03 lbs. The improvement due to experience and cheap coal has thus been 34 per cent. The small fuel costs 5s. to 9s. at the pit. It is machine-washed anthracite Pea coal, and it works best with an 18-inch fire as compared with a 4-foot fire used with the ordinary anthracite of more mixed sizes.

The above figures of cost are total, the fuel cost being ·32d. for the first half of 1896 and ·18d. for the corresponding period of 1897. For this latter period a unit cost 1·42d. when town gas was used. This, we take it, is the fuel cost only. The steam plant at Derby shows a total cost of 2·7d. per unit, and a coal cost of ·38d., while at Sheffield the costs are 2·64d. total, and ·54d. for fuel.

If no town gas were used at Leicester, the cost would only come to 2·67d., but we presume the minimum quantity charged for will always be used. The dynamos are belt driven. It would appear that a saving is thus made in using producer gas in place of steam for motive power. The costs, however, do not seem to include the coal used in the boiler furnace, as special note is made as to fuel cost *at generator*. The use of a boiler always seems somewhat superfluous in a gas producer plant. If more steam is needed than can be taken off in vapour from the gas engine, cooling tanks, or a water hearth, could it not be obtained from a boiler heated by the gases from the generators, which now part with their heat of manufacture in condenser pipes. In the illustration of the plant, the boiler has its separate chimney, and we conclude a separate but probably unnecessary fire also, which must add to production costs, and might be saved.

SOME PRACTICAL POINTS ON THE DESIGN OF A SHUNT DYNAMO.

By V. ZINGLER, A.I.E.E.

(*Concluded from page 7.*)

Core.—This is at once obtained from the difference of magnet bore and air-gap = 17 inches − 1·56 inch = 15·44 inches or, say, $15\frac{3}{8}$ inches to allow for irregularities. Hence the actual air-gap is

$1\frac{5}{8}$ inch = 1 625 in.

Now we can determine the actual number of bars to go on the core as follows :—

Diameter of core	=	15·375 inches
Insulation of core = ·05 × 2	=	·100 inch
Diameter of finished core	=	15·475 inches.

Then

$$15{\cdot}475 \times \pi = 48{\cdot}62 \text{ inches.}$$

This is the net winding circumference. Dividing this by the width of bar we get

$$\frac{48{\cdot}62}{{\cdot}324} = 150 \text{ nearly.}$$

This number of bars would, however, be too great, as there is no room for pegs. These are, say, $\frac{1}{8}$-inch wide, and are fixed every eight bars; our number of bars should also be divisible by eight.

Let us try 144 bars.

144 × ·324 ...	=	46·5 inches
18 pegs, $\frac{1}{8}$-inch wide	=	2·25 „
Space required	=	48·75 inches.

This is obviously too close, and we must take 136 bars.

136 × ·324 ...	=	44 inches
17 pegs, $\frac{1}{8}$-inch wide	=	2·125 „
		46·125 inches.

This leaves about $2\frac{1}{2}$ ins. all round for slack, but when it is compared with the net winding circumference it will be seen that it is only 5 per cent.

The size of the limbs can now be fixed, and for convenience centimetre measure will be used.

$$N = \frac{80 \times 60 \times 10^8}{136 \times 320} \quad \ldots \quad \ldots \quad = 11{\cdot}03 \times 10^6$$

Add for armature losses 2 per cent. ...		·22
„ „ demagnetisation 8 per cent. ...		·88
Total flux	=	12·13 × 10^6

Dimensions of Polar Arc.—This will of course depend on the bore of magnets and on the distance between the limbs. The angle θ (see figure) is frequently fixed so that it is unit angle, *i.e.*, 57°·29—that is when the arc subtending it is equal to the radius. It is, however, near enough to make the distance between limbs half the magnet bore, that is in this case 8·5 ins.

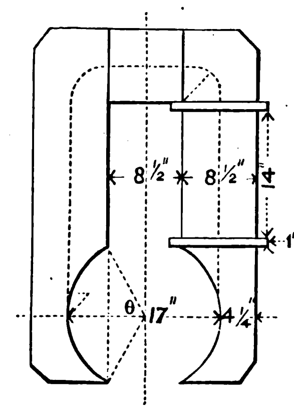

Fig. 1.

Then $\cos\theta = \frac{8{\cdot}5}{17} = {\cdot}5$ which is the cosine of 60°. The radian measure of 60° = 1·047; therefore the total length of polar arc

$$= 1{\cdot}047 \times 8{\cdot}5 \times 2 = 17{\cdot}79 \text{ ins.} = 45{\cdot}14 \text{ cms.}$$

Assuming now that **B** = 5,000 for the air-gap, the polar area will be

$$\frac{12{\cdot}13 \times 10^6}{5{,}000} = 2{,}426 \text{ sq. cms.}$$

Making the usual correction for fringing,

Air-gap 1·56 in. = 3·96 cms.

This multiplied by ·8 ...	=	3·168 cms.
Length of arc	=	45·14 cms.
Corrected arc	=	48·308 cms.

The equivalent length of polar surface will be therefore

$$\frac{2{,}426}{48{\cdot}308} = 50 \text{ cms.}$$

and the actual length will be

$$50 - 3{\cdot}168 = 46{\cdot}832 \text{ cms. or } 18\tfrac{1}{2} \text{ ins.}$$

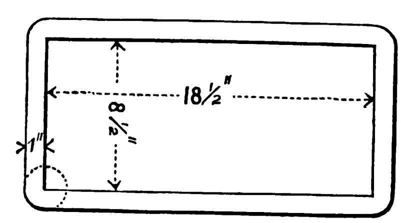

Fig. 2.

Width of Magnet Limbs.—Assuming an induction

B = 16,000

and the coefficient of leakage as 1·3 we get

$$\frac{12{\cdot}13 \times 10^6 \times 1{\cdot}3}{16{,}000} = 985 \text{ sq. cms.}$$

The width of iron therefore is

$$\frac{985}{46{\cdot}832} = 21 \text{ cms.} = 8\tfrac{1}{4} \text{ ins., say } 8\tfrac{1}{2} \text{ ins.}$$

The dimensions of magnet limbs are, therefore, $8\frac{1}{2} \times 18\frac{1}{2} \times 17$ bore.

It only remains to fix the length, which depends almost entirely on the bobbins, the ampere-turns required for the iron circuit being small compared to those necessary for the air-gap. As a rule, if the dynamo is well proportioned, the length of limb from yoke to armature should not be longer than the diameter of the armature, and this space should include the bobbin cheeks, which are, say, 1 inch in thickness. Let us then take 14-inch bobbins. If a line is drawn round the frame in the centre of the limbs, this will be the approximate mean path of the magnetic lines, and can be summed up as follows:—

Bobbins and cheeks, 16×2	=	32 inches.
Yoke	=	8·5 inches.
Top circles $\frac{8\cdot5\,\pi}{4} \times 2$ ...	=	13·35 inches.
Bottom circles $\frac{4\cdot25\,\pi}{4} \times 2$...	=	6·67 inches.
Balance $\left(8\cdot5 - \frac{4\cdot25}{2}\right) \times 2$	=	12·75 inches.
Total length of magnetic path	=	73·27 inches
= 186 cms.		

Ampere-Turns.—The method often employed is to work out the magnetic reluctances of the different parts, and the products of these and the total flux N give the respective ampere-turns required. This can, however, be done in one operation.

The fundamental C.G.S. formula is

$$\text{M} = \text{N R},$$

where M = magnetomotive force and R = magnetic reluctance. Or, if we require ampere-turns, we must multiply by

$$\frac{10}{4\pi} = \cdot7958.$$

R is, however, equal to $\frac{l}{\mu a}$,

or the length of material divided by the area and the coefficient of permeability, just as in electricity where μ is replaced by the specific conductivity.

We therefore have

$$\text{Ampere-turns} = \frac{\text{N}\,l}{\mu\,a} \times \cdot7958$$

and, as $\frac{\text{N}}{a}$ = B or the induction per square centimetre, we simply have

$$\text{Ampere-turns} = \frac{\text{B} \times l}{\mu} \times \cdot7958.$$

Taking the air-gap first, it is still necessary to get B for the effective polar area.

This is

$$45\cdot14 \times 46\cdot832 = 2{,}100 \text{ sq. cms.}$$

$$\text{B therefore} = \frac{12\cdot13 \times 10^6}{2{,}100} = 5{,}750.$$

Hence

$$\text{Ampere-turns for air-gap} = \frac{3\cdot96 \times 5{,}750 \times \frac{10}{4\pi}}{1} = 18{,}000$$

$$\text{Ampere-turns for iron} = \frac{186 \times 16{,}000 \times \frac{10}{4\pi}}{\text{say } 300} = 8{,}000$$

$$\text{Total ampere-turns} \quad \ldots \quad \ldots = 26{,}000.$$

The ampere-turns for the armature may in this case be neglected, as with a small induction, and a high permeability as is usually the case now, they only run into hundreds.

Winding Field Magnet Bobbins.—This is perhaps the most troublesome operation in designing a dynamo, and unless the designer has some experience, the calculations have often to be repeated two or three times. Our object is not only to get on the necessary ampere-turns, but also to see that the watts are in such proportion to the radiating surface that they do not cause overheating. In order to attain this end, the watts per square inch of radiating surface should not be higher than 1·5, and in calculating the radiating surface the two sides of the bobbins inside the magnet limbs should be neglected. The whole point is to be able to gauge the right depth to which we shall wind.

Let the bobbins in this case consist of iron sleeves slipped over the limbs, of a total thickness, including the insulation, of ·3 inch, or 1·2 inch all round (four sides).

As we have to put on 26,000 ampere-turns, the resistance of a mean turn will obviously be

$$\frac{80}{26{,}000} = \cdot003077 \text{ ohm.}$$

Let us try winding to a depth of 2 inches.

Referring to fig. 2, the length of a mean turn will be:

$$2\,(18\cdot5 + 8\cdot5) + 1\cdot2 + 2\,\pi = 61.48 \text{ ins.}$$

Assuming that the designer has a table of resistances and wires before him, we proceed—

$$\text{Resistance of 1,000 feet} = \frac{\cdot003077 \times 1{,}000 \times 12}{61\cdot48} = \cdot6005 \text{ ohm.}$$

On referring to a wire table, we see that copper wire, ·1299 inch diameter, has a resistance of ·60647 ohm per 1,000 feet. This is near enough.

Number of Turns in one Layer:—

Diameter of copper wire	·1299	inch.
d.c.c. insulation	·016	„
	·1459	„
Allow for slack, 5 per cent ...	·0073	„
Gross diameter of wire ...	·1532	„

Our bobbin is 14 inches high, therefore the number of turns $= \frac{14}{\cdot1532} = 91$ turns.

Number of Layers:—

Diameter of copper wire	·1299	inch.
d.c.c. insulation	·016	„
	·1459	„
Allow for slack, 20 per cent. ...	·0292	„
Gross diameter of wire	·1751	„

The winding is 2 inches deep, therefore the number of layers is

$$\frac{2}{\cdot1751} = 11 \text{ layers.}$$

Total number of turns $= 11 \times 91 \times 2 = 2{,}002$, say, 2,000 turns.

Now the resistance of a mean turn will be

$$\frac{\cdot60647}{2{,}000} = \cdot00303 \text{ ohm,}$$

and the total resistance of the shunt winding = 6·06 ohms. The watts lost in the shunt will be

$$\text{E C} = \frac{\text{E} \times \text{E}}{\text{R}} = \frac{80 \times 80}{6\cdot06} = 1{,}056 \text{ watts.}$$

The radiating surface is arrived at thus: Length of outside turn $= 2\,(18\cdot5 + 8\cdot5) + 1\cdot2 + 4\,\pi = 67\cdot76$ inches.

Subtracting one side, $67\cdot76 - 18\cdot5 = 49\cdot26$, we get for total radiating surface $49\cdot26 \times 14 \times 2 = 1{,}375$ sq. ins.

The square inches per watt will therefore be:

$$\frac{\text{turns} \times \text{radiating surface}}{\text{volts} \times \text{ampere-turns}} = \frac{1{,}375 \times 2{,}000}{80 \times 26{,}000} = 1\cdot32 \text{ sq. inches,}$$

which is a figure that will give good results.

We can inquire further into the electrical efficiency; the shunt current will be $\frac{80}{6\cdot06} = 13\cdot2$ amperes, or about 3 per cent. of the armature current; the watts lost in the shunt are $80 \times 13\cdot2 = 1{,}056$, and therefore the electrical efficiency

$$= \frac{32{,}000}{33{,}056} = 97 \text{ per cent. nearly.}$$

This neglects the armature losses which may be a further 2 per cent., and which are easiest to measure after the machine is finished. The total actual ampere-turns will now be $13\cdot2 \times 2{,}000 = 26{,}400$ which is only about $1\frac{1}{2}$ per cent. higher than what we require by calculation.

To recapitulate and conclude; these notes only refer to the materials and the size and type of machine herein set forth, and are intended more as a demonstration of the method of winding a machine in practice, than of the calculations of the size and magnetic properties of the dynamo, albeit these have also been touched on so as to make the whole complete. In actual practice however, and after a certain number of dynamos have been built, it is the winding only which requires re-calculation (within limits) the other properties being proportioned from existing types.

THE MONTAUK MULTIPHASE FIRE CABLE.*

The United States have won a well deserved reputation for the high state of efficiency to which they have brought their appliances for fire extinguishment. It is generally admitted that the best fire departments of other countries are greatly inferior to the splendid institutions which are maintained in our leading cities. Not only is our equipment for "fighting fire" practically perfect, but there has been a wonderful amount of ingenuity displayed in the invention of devices for automatically locating and announcing an outbreak of fire. These inventions have taken the form of thermostats, which automatically close an electric circuit when the local temperature passes a certain point. The thermostats are scattered throughout a building in various places, which in the judgment of the owner are most likely to be visited by a fire. If the outbreak should occur immediately below a thermostat, the circuit will be closed and the alarm rung in immediately. If, however, the fire should start at a point intermediate between two thermostats, there would be more or less delay until the temperature reached the proper degree to operate the alarm.

The ingenious and well-thought-out system of fire alarm which we illustrate in the accompanying engravings, is the logical development of the usage of the thermostat above referred to. In place of a set of wires connecting a number of isolated thermostats, the whole wire itself is so sensitive that the mere heat of a lighted match (see fig. 3) applied at any point of the wire will cause the metal to fuse and ring in an alarm. As the value of a fire alarm consists chiefly in the rapidity with which it will act, upon the outbreak of a fire, it is evident that the efficiency of the "fire cable" is enormously increased over that of ordinary systems.

The construction of the cable and the details of the wiring are shown in the accompanying figures. The cable, fig. 1, is made up of an inner copper wire, which is coated with a metal that fuses at the low temperature of 374°. The fusible metal alone would serve to carry the current, but the copper is introduced to increase the conductivity. Around the fusible metal is wrapped a suitable insulation, and over this again is wrapped a series of smaller wires with insulations between them, as shown in the sketch, the whole being covered with an outer protective wrapping. One of the outer wires serves the fire alarm, another the burglar alarm, another may be used for the servants' call, and others may be added to serve a multiplicity of electric connections.

* *Scientific American.*

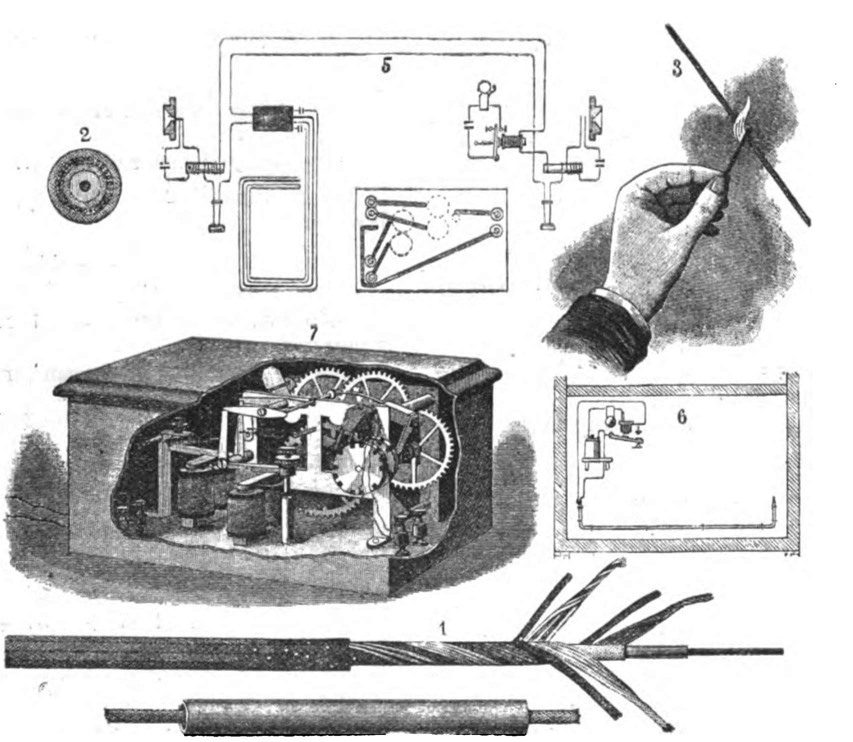

Fig. 4.

When a fire breaks out in the neighbourhood of the wire, the heat fuses and expands the inner fusible coating and forces it out through the insulation into contact with the overlying return wire, thus forming a metallic contact between the inner and outer wire, closing the circuit and turning in an alarm. Fig. 6 shows the cable laid in a room and connecting with an audible fire alarm in the house. Fig. 5 is a diagram showing the cable connected to an automatic circuit-controller in the house or on the street, through which the alarm is automatically forwarded to the central fire station.

When the circuit is automatically closed by an outbreak of fire, the current energises the magnets in the controller (fig. 7), which then act upon a system of small levers and release a clock mechanism. The latter serves to rotate the two controlling discs, which, by means of make and break contacts, ring up the call corresponding to the location of the fire and show the corresponding number in the annunciator. The discs are so arranged that they repeat the alarm at the central station.

A valuable feature of this cable is that it forms an effective burglar alarm; for if a burglar should attempt to destroy the ordinary window alarm by breaking the window glass and cutting the wires, the pliers will form a metallic connection between the inner and outer wires of the cable and close the circuit. To avoid error in connecting up the return wires they are made in different colours. Thus the fire alarm wires are of copper, another set are copper wires tinned, and a third will consist of alternate tinned and copper wires (see fig. 1). To keep down the bulk of the return wires each set consists of several fine wires whose aggregate cross section is sufficient to make up the necessary conducting area, and they are wrapped in ribbon fashion around the insulation. Considering the complicated nature of the cable and the duty that it performs, its bulk is remarkably small.

The advantages of the cable are obvious. Not only does it provide a building with continuous lines of protection, but the sensitive wires themselves are so small as to attract no more attention than ordinary house wiring. It may be laid along the moulding, across a window or door, within the cornice, above the shelves in a store, without attracting the eye, or in any way interfering with the decorative features of the building. For detecting a fire, due to spontaneous combustion in the coal bunkers or hold of a ship, the wires would be laid in pipes, fig. 4, which would protect them from rough usage but leave them exposed to the action of heat. The various patents which cover this device are owned by the Montauk Multiphase Cable Company, 100, Broadway, New York, to whom we are indebted for the particulars given above.

Banquet.—From the *Western Mail* of Cardiff we learn that a banquet was given on Friday night last at the Whitehall Club to Mr. Samuel Insull, of the Chicago Edison Company, by Messrs. Arthur Wright and W. L. Madgen.

THERMIC EQUILIBRIUM IN ELECTROLYSIS.

By M. D. TOMMASI.

The problem that we propose to solve is as follows:—*Given a chemical compound capable of being oxidised or reduced, find out how it behaves when it is brought at the same time into the presence of a reducing and an oxidising substance, which are considered to be equal and contrary forces.*

Theoretically, only two cases are possible.

1. The two forces neutralise one another, and the compound evidently remains in equilibrium.

2. One of the forces overpowers the other.

According to thermic data this is what should happen:—

Let the compound, for instance, be termed A B; we subject it to a chemical action ($H^2 + O$); three cases may present themselves for consideration:*

(*a*). The compound A B will not be subjected to any action if

$$c\,A\,H^2 + c\,B\,O = c\,A\,O + c\,B\,H^2,\dagger$$

i.e., if the compound A B gives off the same quantity of heat when becoming oxidised as when being reduced.

(β). The substance A B will be reduced if $c\,A\,H^2 > c\,B\,O$.

(γ). The substance A B will be oxidised if $c\,A\,H^2 < c\,B\,O$.

For the sake of clearness, let us take an example: we will subject nitric acid to the action of ($H^2 + O$). In this case the reduction of the nitric acid can only take place if the hydrogenisation of this acid gives off more heat than the oxidisation of ammonia. Now, according to thermic data the formation of ammonia by the reduction of nitric acid gives off more heat than the oxidisation of ammonia.

In fact

$$N\,O^3\,H + 4\,H^2 = N\,H^3 + 3\,H^2\,O\,;\ 179{\cdot}2 \text{ cal.}$$
$$N\,H^3 + 4\,O = N\,O^3\,H + H^2\,O\,;\ 96{\cdot}8\ \text{,,}$$

Therefore, the nitric acid will be totally reduced by (H^2+O) unless an opposite reaction can take place; which conclusion is fully borne out by experiment. The mixture ($H^2 + O$) is obtained by the electrolysis of water, with the aid of three bichromate of potash Bunsen elements.‡

The gases are thus liberated in the ratio of their molecular weight, and under the same chemical and physical conditions.

The electrodes are of platinum and very close together. The liquid which is being experimented upon is frequently stirred and the current is reversed alternately.

We can sum up in the following table the results at which we arrived by subjecting various chemical compounds capable of being reduced or oxidised by the simultaneous action of electrolytic hydrogen and oxygen.

Action of ($H^2 + O$) on different chemical compounds:—

Original compound.	Final compound.
Nitric acid	Ammonia and nitrite.
Nitrate of potassium.	———
" sodium	
Nitrite of potassium	Ammonia.
Chlorate of potassium	Perchlorate.
Arsenical acid	No change.
Arseniate of potassium	———
Arsenious acid	Arsenical acid.
Arsenite of potassium	Arseniate.
Ferrous sulphate	Partial oxidisation.
Ferric sulphate	Partial reduction.

From the results of these researches we can deduce the following laws:—

1. *When a body is subjected to two equal and contrary chemical actions, the reaction which gives off the greatest quantity of heat will be most likely to be produced, provided that it can be begun.*

Examples: The oxidisation of the arsenious acid and of the alkaline arsenites. The reduction of the nitric acid and of the vegetable nitrites.

2. *With two chemical reactions, the one that requires the least heat to begin will always be produced in preference, even if it gives off less heat than the other reaction.*

Examples: The oxidisation of the chlorate. The partial reduction of the ferric sulphate and the partial oxidisation of the ferrous sulphate.

In the case of the chlorate of potassium, for instance, the heat or energy required to effect the union of the hydrogen with the oxygen of the chlorate must be greater than that required for producing the combination of the oxygen with the chlorate, and this is no doubt the reason why the chlorate was transformed into perchlorate rather than chloride, although the oxidisation of the chlorate gives off less heat than its reduction. For the same reason, if the ferric sulphate* is reduced by ($H^2 + O$), it is due to the fact that the heat or the energy required to effect the union of the hydrogen with the oxygen of the ferric sulphate is greater than that given off by the combination of the electrolytic oxygen with the ferrous sulphate,† and if the reduction is not total, but partial (60 per cent.), this is due to the fact that having arrived at this point a sort of equilibrium is established between the reduction of the ferric sulphate on the one hand and the quantity of ferrous sulphate formed on the other hand, an equilibrium similar to that which is observed when we electrolyse a mixture of varying proportions of nitrate of copper and nitrate of silver.‡ We may mention, in conclusion, the following fact, which will show indisputably that the principle of the maximum work and its reciprocal Sprague's law§ are only true on the express condition *that the reaction between the bodies brought together can be begun.*

If we acidulate a solution of bioxide of hydrogen ($H^2\,O^2$) with sulphuric acid, we get at the negative pole an abundant escape of hydrogen, due to the decomposition of the water without this hydrogen reducing the bioxide of hydrogen. Now, how can we explain the fact that this nascent hydrogen‖ which, although it reduces a number of substances the decomposition of which absorbs heat, has no effect on the bioxide of hydrogen, the decomposition of which takes place with a liberation of heat?

In other words, why does the electric current decompose the water, the heat of decomposition of which is − 69 cal., rather than act on the bioxide of hydrogen, the heat of decomposition of which is + 21·6 cal. We observed¶ a similar fact with the following couple:—

Zinc, acidulated water; porous jar, bioxide of hydrogen, with the addition of a drop of solution of sulphate of copper. Platinum.

In this couple, in fact, the deposit of copper on the platinum is produced as soon as the circuit is closed and long before the bioxide of hydrogen has been decomposed.

We observe, then, in this couple the singular fact that the hydrogen given off by the decomposition of the water reduces the sulphate of copper (an exothermic compound), the decomposition of which absorbs heat rather than the bioxide of hydrogen (an endothermic compound), the decomposition of which, on the contrary, is attended by giving off of heat.

* It is supposed, in all three cases, that the same quantity of heat or energy is required to commence the chemical reactions.

† c = heat of formation.

‡ For fuller details see "Treatise on Electric Batteries," by D. Tommasi, p. 200 (published by G. Carré, Paris).

* $(S\,O^4)^3\,Fe^2$.

† $S\,O^4\,Fe$.

‡ See "Traité théorique et pratique d'électro-chimie," by D. Tommasi, p. 25 (published by Bernard, Paris).

§ The substances liberated at the electrodes are those which, in escaping, absorb the least specific energy.

‖ The researches that we made in 1877 showed that if hydrogen in a nascent state is a powerful reducer, it is due solely to the fact that this body, at the moment it leaves, a combination is accompanied by all the heat produced at its escape. Consequently nascent hydrogen is synonymous with H + cal. (hydrogen + ealories) and the differences observed between hydrogen given off by different chemical reactions, are due to the fact that these reactions do not develop the same quantity of heat.

¶ See "Traite théorique et pratique d'électro-chimie," by D. Tommasi, p. 526.

SHIELDED CONDUCTORS.

By W. A. PRICE.

Mr. Mordey's paper on "Dynamos," read on May 20th, before the Institution of Electrical Engineers, has produced a long series of articles and letters in different periodicals, proposing and solving a number of paradoxes and puzzles of more than usual interest. Some of these are curious and excellent examples of magnetic problems that can be dealt with sufficiently by the application of first principles, though complete solutions would be difficult mathematical exercises. The first puzzle proposed was not new, having been described years ago by Mr. James Swinburne; but its interest was revived by an experiment described by Mr. Mordey. The difficulty is to explain how a conductor buried in the iron of a slot-wound armature experiences very little mechanical force, though it is equally as efficient in developing electromotive force in a dynamo, as if it were exposed on the surface of an ordinary drum armature, and has just the same effect in producing torque in a motor.

The electromotive force developed in a conductor is simply proportional to the number of lines of force crossing it in a given time. The mechanical force on a conductor is proportional to the product of the current, and the density of the magnetic field in its own substance; and the difficulty lies in seeing how the magnetic field in the body of the slot-wound conductor can be so small that no appreciable force is exercised on the conductor, while, at the same time, it is cutting a field of sufficient intensity to generate a large electromotive force. The answer is, of course, that in a slot-wound armature the conductors are so shielded by the iron body in which the slots are cut that only a very small part of the total magnetic flux passes through them at any given instant, and the force acting on the conductor is correspondingly small; while at the same time the total flux cut by any conductor in the course of the revolution of the armature is not affected.

Figs. 1 and 2 are diagrams of the usual character, showing the distribution of the lines of magnetic flux near the air gap in a slot-wound armature. The upper part in each

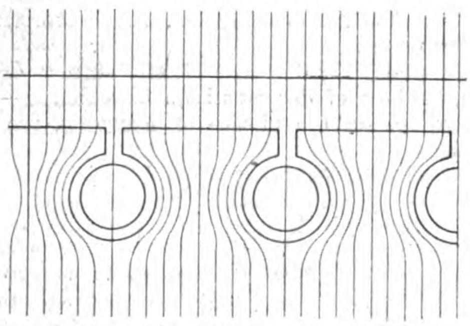

Fig. 1.

figure represents parts of a magnet pole, while the conductors are shown in round slots cut in the body of the armature. The air-gap is shown straight instead of an arc of a circle for convenience in drawing. Fig. 1 gives the arrangement of the lines of magnetic flux when there is no current in the conductor. The field in the body of the conductor is extremely weak, but as the armature is rotated the lines of flux are carried across the conductor, moving slowly in the mass of the iron, but flashing across the slot at great

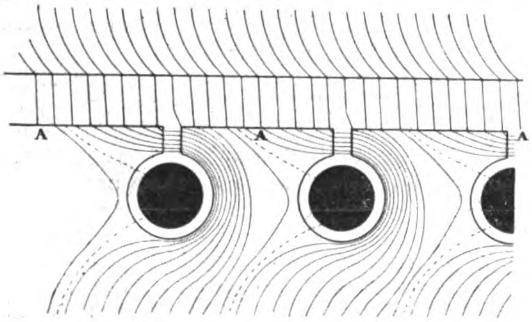

Fig. 2.

speed. But no figure explains the movement as well as Mr. Swinburne's comparison of the action to the appearance of a row of railings passing behind a knot in the window of a railway carriage, producing an appearance similar to fig. 1.

Fig. 2 gives the arrangement of the lines when a current is passing in the conductor. It is obtained by imposing on fig. 1 a system of magnetic forces, circular about the conductors, producing distortion of the field. The distortion does not affect the reasoning already given about the forces acting on the conductors, and the electromotive forces developed; but the figure shows how it is that the weakness of the field in the body of the conductor does not affect the torque on the armature. The points of application of the forces which produce the torque lie on the surface of the armature, where the lines of force enter it from the ether, viz, along the surface, A A A. In fig. 1 these lines enter the surface normally, and produce no torque; but when a current is started in the conductors, the lines of force in the air-gap become slightly oblique, as shown in fig. 2, in consequence of the circular systems of magnetic forces about the conductors, and a torque is developed. The whole of the useful effect is obtained from the slight displacement in the air-gap. The large displacement of the lines in the body of the armature serves no useful purpose. The magnetic force in the air-

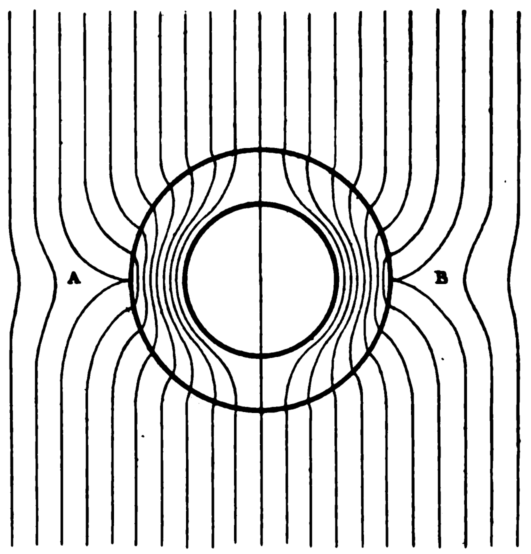

Fig. 3.

gap, due to the current in the conductor of circular section, is at all points inversely proportional to the distance from the axis of the conductor, and is in no way shielded by the iron body of the armature.

Another advantage possessed by slot-wound conductors, that they are less heated by eddy currents than surface conductors, can only be due to a very steady movement of the lines of flux across the slots, so that all parts of any conductor are cutting lines at the same rate. It is no explanation to say that, since the field in which the conductor lies is weak, even large percentage variations in its density are immaterial; for the absolute density has no relation to the generated electromotive force. The exact explanation of what is undoubtedly the fact, viz., the freedom of slot-wound conductors from eddy current heating, is not very clear.

A remarkable statement has been made by Prof. du Bois, from whose article in the *Elektrotechnische Zeitschrift* we extract the following passage:—

"A ring magnet experiences a side thrust when in an external field, whose lines of force are in the same plane as the ring; and conversely it exerts a thrust in the opposite direction upon the supporter of the external field. This deduction, so astonishing at first sight, I have proved to be verified by experiment."

Though not expressly stated, it seems to be implied that the field is uniform, except so far as the ring distorts it, the ring homogeneous and uniformly magnetised, and the thrust experienced a continuous one, and not merely impulsive or ballistic on completing the connections. We take "side thrust" to mean a thrust in the plane of the ring, at right angles with the field, but it may mean a thrust in the direction of the axis of the ring. Each construction presents the same difficulties. Such a field and ring may be realised by permanent magnets, and by arranging the ring to turn about an axis "perpetual motion" is obtained.

Mr. James Russell disputes the truth of this "deduction" on experimental evidence, while it is totally opposed to conclusions drawn from the ordinary premises, which would lead us to reason somewhat thus. If an iron or steel anchor ring, unmagnetised, be introduced into an uniform magnetic field, the field is distorted from its previous form in some way depending on the permeability of the ring and its position in the field. If the ring is placed with its plane parallel to the field, it will experience no force tending to move it in space. There will be forces tending to elongate it into an oval, but these would not produce any such effect as that discovered by Prof. du Bois. Now, without moving it, suppose the ring to become circularly magnetised. This magnetisation, though it produces a new distortion of the field in the body of the ring, produces none in the field outside the ring, which retains the same form and distribution as before, so that the ring experiences no force.

Figs. 3 and 4 show the character of the field near the ring before and after its magnetisation.

In these diagrams we have taken no account of the effect on the permeability of the different flux densities on the two

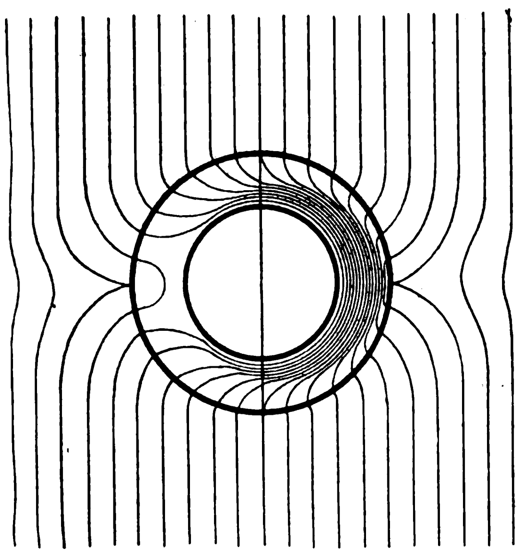

Fig. 4.

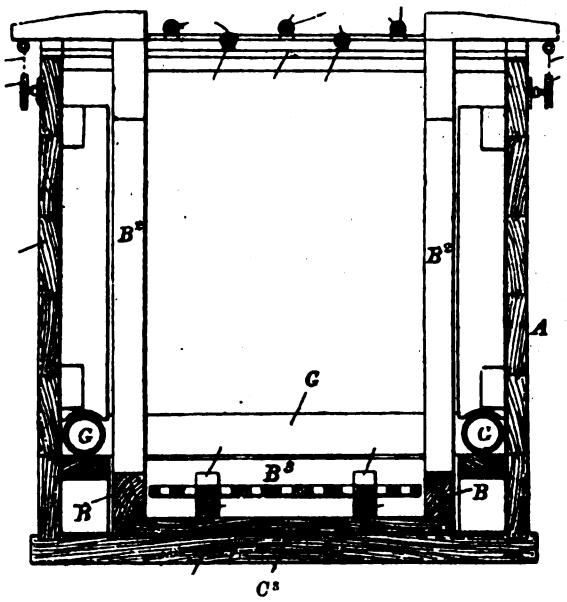
sides of the ring. This would change the field distribution to a form that would be produced by an unmagnetised ring which is non-homogeneous, but symmetrical about the axis A B of fig. 3, being less permeable on the side B than on the side A. This change of field taking place when the ring is magnetised, would produce a sudden and transient force acting on the ring in the direction B—A, and it is possible that this is the effect Prof. du Bois has observed. His words do not exclude such a construction. The action would not occur with a circular or ring solenoid.

(*To be concluded.*)

REMOVAL OF MILL SCALE BY ELECTROLYSIS.

By SHERARD COWPER-COLES, M.I.E.E., Assoc.M.Inst.C.E.

The removal of mill scale from forgings and plates has always been a matter of considerable difficulty, the scale in many cases being $\frac{1}{32}$-inch in thickness, and very adherent. The usual practice is to place the iron in a solution containing 1 part of hydrochloric or sulphuric acids to 10 parts of water, for a period varying from 2 to 24 hours. Many attempts have been made to quicken the process and to reduce the cost. One of the first experiments was to make the iron to be pickled, the anode in an acid bath; but this was found to pit the plates, as the iron which was not protected by the mill scale was more readily dissolved than that covered by the magnetic oxide. To overcome this difficulty the current was reversed, the iron being alternately made anode and cathode. The illustration shows a transverse section of a pickling vat constructed for such a process, the work being suspended on the bars placed across the vat. To quicken the process and reduce the electrical resistance of the solution, it is found advantageous to heat the pickling solution or electrolyte, which is done by means of a lead pipe, G, through which exhaust steam is passed. In the illustration a tray or false bottom, C^3, is shown, capable of vertical movement between guides provided on the inside of the vat; the object of the tray being to catch the heavy mill scale which falls from the plates. The tray at the end of the day's work is allowed to float by releasing the paul from the winch to the top of the solution so that the mill scale collected on it can be removed. To sink the tray when necessary, extensions, B^3, are provided at each corner, and these extensions are connected to flexible connections which pass round guide sheaves, and are connected to a drum or winch which is rotated when it is desired to sink the tray.



Cross Section.

Another device for catching the scale soon after it is removed from the plates, so as to prevent the further unnecessary consumation of acid by dissolving the mill scale after removal has been tried with most satisfactory results. The solution is circulated by means of a small pump through a lead-lined box or chamber, behind which are placed electromagnets, the result being that as the solution flows past the poles of the magnets the magnetic iron in suspension is retained and can be removed from time to time.

In America an electrical pickling process has been tried. The solution used being sulphate of soda or sulphuric acid. The plates to be cleansed form the negative electrode and an iron plate the positive electrode. The hydrogen set free from the surface of the plate reduces the oxides on the surface, and decomposes any grease that may be present.

Attempts have been made to remove the mill scale by drawing it away from the plates with powerful electromagnets, the scale having been previously loosened by a short immersion in an acid bath, or by heating.

THE PROPER CONSTRUCTION AND USES OF ECONOMISERS.

The word economiser has a general meaning, but in steam using parlance an economiser has come to mean a special piece of apparatus, to wit, a flue feed heater, made of tubes, and every engineer who speaks of an economiser almost invariably means one with vertical pipes of the Green type. These are so common in England that they may be said to be universal in the textile districts, and, as stated by Mr. Brinckerhoff in a paper read before the New England Cotton Manufacturers' Association, they are in use all over Europe, and in the mills of India or the mines of South Africa, and have already been widely adopted even in the United States.

It appears that economisers have rather been failures in the United States in many instances, this being due to the use of material other than cast-iron, which alone seems to have the power to resist the corrosive action of sulphurous gases. In this respect an economiser differs somewhat from a boiler. The latter is hot and does not condense on its surface steam from the gases passing over it.

The economiser is fed with cool or cold water, and the tendency to condensation of acid vapours on its surface is much greater, and even cast-iron pipes suffer much at their lower ends, as we have pointed out years ago. Indeed, Messrs. Green now provide against this by using a part of the economiser as a first section to warm the water before passing it on to the remaining lower boxes. In this way they save the lower ends of, say, five-sixths of the pipes by allowing the whole of one-sixth of the pipes to be attacked.

Another cause of failure has been the lack of capacity. An economiser requires to be of such size that the water passing through it should take from 30 to 50 minutes. This gives time for heat absorption. Many economisers have not been fitted with automatic cleaning gear, and soot being so poor a heat conductor, a few hours are sufficient to render an economiser nearly useless if not automatically cleaned. Attention to the three essentials—cast-iron, capacity, and cleaning—has made the success of Green's economiser. The further important items are, an absence of made or packed joints, the pipes being forced, metal to metal, in the sockets of the top and bottom boxes by hydraulic pressure, and finally tested to 350 lbs. A well-made economiser has a life of 20 years, and can be so repaired in sections as to become practically a new apparatus, while preserving its old identity like a repaired umbrella which contains nothing of its original parts.

But economisers require care; they should be blown out when the boilers are blow off; they should be periodically cleared of soot below, and yearly, at least, the top caps need removal for purposes of inside inspection. Also, we would add, they must be bored out when scaled. Boring out is quite a branch of the economiser business, and pipes can be bored clean of scale very easily by means of the special boring bars sent out for the purpose by the makers. It is the practical necessity of boring out an economiser which has prevented the success of many economisers constructed on different lines. We have seen economisers made in the form of a helix, most ingeniously cast, but quite incapable of being bored out. Again we have seen them with the water passages of the pipes made of segmental cross-section—also not to be bored out. Of course, water ought not to contain lime salts. But unfortunately it does, and no economiser maker can afford for long to ignore the fact. Apart from the *bonâ fide* saving effected by an economiser, the increase of the capacity of a plant afforded by it and the saving in repairs to boilers by reason of the abolition of cold feed, and the saving in cleaning because of the deposition of much scale forming matter in the economiser in the form of mud, the apparatus is specially useful when work fluctuates. A sudden demand for steam, of which a heavier feed is the obvious concomitant, is not followed by the drop in pressure which accompanies a large influx of cold feed. An economiser is, in fact, a species of thermal storage with a good system of circulation. It adds to the water space of a boiler and must be an immense benefit to water-tube boilers, whose chief fault is perhaps a deficiency of water capacity.

NEW PATENTS AND ABSTRACTS OF PUBLISHED SPECIFICATIONS.

NEW PATENTS.—1897.

[*Compiled expressly for this journal by* W. P. THOMPSON & Co., *Electrical Patent Agents*, 322, *High Holborn, London, W.C., to whom all inquiries should be addressed.*]

30,572. "Improvements in joints for electricity conductors." G. C. FOWLER and THE MUTUAL ELECTRIC TRUST, LTD. Dated December 28th.

30,619. "Improvements in primary galvanic batteries or cells." J. W. BULLOCK. Dated December 28th.

30,622. "A combined manual and automatic switch for electric circuits." R. L. HAILEY. Dated December 28th.

30,626. "Improvements in the method of and means for regulating the phase relation between current and electromotive force in alternating current systems of electricity distribution." THE BRITISH THOMSON-HOUSTON COMPANY, LTD. (C. P. Steinmetz and E. W. Rice, jun., United States.) Dated December 28th. (*Complete.*)

30,627. "Improvements in and relating to electric railways." THE BRITISH THOMSON-HOUSTON COMPANY, LTD. (W. B. Potter, United States.) Dated December 28th. (*Complete.*)

30,628. "Improvements in induction watt meters." THE BRITISH THOMSON-HOUSTON COMPANY, LTD. (E. Thomson and W. H. Pratt, United States.) Dated December 28th. (*Complete.*)

30,678. "A new or improved method of retransmitting telegraphic messages and apparatus for use in connection with the said method and for other purposes." J. RYMER-JONES. Dated December 28th.

30,815. "Improvements relating to animated photographs." W. J. H. JONES. Dated December 30th.

30,832. "Improved arc lamp carrier." J. BROCKIE. Dated December 30th.

30,838. "Improvements in apparatus for use in the manufacture of accumulator plates." C. MARSCHNER. Dated December 30th. (*Complete.*)

30,841. "Improvements in electrolytic apparatus." G. C. MARKS (H. de Solages, France.) Dated December 30th.

30,846. "A method or methods for controlling a mechanism or mechanisms by means of electric or electro-magnetic waves of high frequency." E. WILSON and C. J. EVANS. Dated December 30th.

30,848. "Operating railway points by electro-motors." I. A. TIMMIS. Dated December 31st.

30,881. "A new or improved method of electrical signalling." S. J. MOTTON. Dated December 31st.

30,912. "Improvements in electrical resistance apparatus." H. A. MAVOR and MAVOR & COULSON, LIMITED. Dated December 31st.

30,997. "Improvements in electrically operated clocks." R. BURK. Dated December 31st. (*Complete.*)

30,923. "Improvements in electric elevators." H. H. LEIGH. (F. J. Sprague, United States.) Dated December 31st.

ABSTRACTS OF PUBLISHED SPECIFICATIONS.

Copies of any of these Specifications may be obtained of Messrs. W. P. THOMPSON & Co., 322, High Holborn, W.C., *price, post free*, 9d. *(in stamps)*.]

1896.

17,161. "The manufacture of an active material for the plates or electrodes of electric accumulators." S. HAMMACHER. Dated August 4th, 1896. Relates to the active material of secondary batteries, which consists of a lead oxide mixed with substances of the pyridine group in the presence of water.

17,187. "An improved electric cable or conductor for electric fire or other alarm systems." C. D. TISDALE and J. D. GOULD. Dated August 4th, 1896. Conductors are formed with a core of lead or lead on copper, surrounded by an inflammable insulating material such as India-rubber, or fibre and resin. One or more wires are then laid in long spirals over the insulation and further insulated if desired. The wires are fixed round a room and are connected to a bell magnet and battery. The action of the magnet is to form a short circuit across the leads when once the alarm is given. The contact between the wires may also be formed by pinching or cutting as in burglar, &c., alarms.

17,659. "Receptacle for electric and other wire." E. F. JONES. Dated August 10th, 1896. Conduits in the form of kerbs constructed as open-ended boxes, fitting together by rabbet joints. The outer side is strengthened, and removable lids are provided for inspection of the wires or tubes. The conduits may be of iron, wood, &c., and the joints are packed with pitch and the like.

1897.

13,107. "Improvements in electric arc lamps." S. BERGMANN Dated September 4th, 1897. Relates to arc lamps, especially where the arc is maintained in a small inner globe. The frame of the lamp is so constructed that the inner and outer globes can descend so far below the base of the lamp as to easily permit the introduction of new carbons without risk of breakage. A removable and adjustable electric contact making holder is provided for the upper carbon, by which the vertical length of the lamp is very much reduced, and a fusible conductor for leading the current to the upper carbon is avoided. The chamber enclosing the arc has a valve-shaped top seated in the portion of the lamp which supports the carbon feeding and regulating mechanism. This top has an opening for the passage of the upper carbon. There is a carbon-holder in the shape of a cylindrical tube provided with means for securing the carbon, and with adjustable springs for ensuring electrical contact between the directing tube and carbon-holder. With the supporting frame are a pair of tubes, with links pivoted on their ends. A pair of tubes within the former carry a yoke provided with off sets, with which the links engage, and a pair of wires within them carrying a support for the outer globe, with a releasing device. 7 claims.

ELECTRICAL REVIEW.

VOL. XLII. JANUARY 21, 1898. No. 1,052.

CONTENTS:

THE ELECTRICAL REVIEW.

Published every FRIDAY, Price 4d.

The Oldest Weekly Electrical Paper. *Established* 1872.

TO BE OBTAINED BY ORDER FROM ANY NEWSAGENT IN TOWN OR COUNTRY.

OFFICE:—4 LUDGATE HILL, LONDON.

Telegraphic Address: "AGEEKAY, LONDON." Code A B C.

Telephone No. 988 Holborn.

ALL Letters should be addressed to the Proprietors, H. Alabaster, Gatehouse & Co.

ADVERTISEMENT RATES ON APPLICATION.

The "Electrical Review" is the recognised medium of the Electrical Trades.

SUBSCRIPTION RATES.—In *Great Britain*, Post Free per Year, 19s. 6d. To all *other countries*, per Year, £1 4s.

BINDING.—Subscribers' numbers bound, including case, for 4s. each volume.

CASES.—Cloth Cases for Binding can be had, price 2s. 6d. each.

READING CASES, to hold from One to Twenty-six Numbers until the Volume is complete for Binding, can now be had from the Publishers, Price 6s. or Free by Post (in Great Britain), 6s. 6d.

FOREIGN AGENTS.—*New York:* D. VAN NOSTRAND, 23, Murray Street. *Paris:* VEUVE J. BOYVEAU, 22, Rue de la Banque. *Berlin:* ASHER & Co., 5, Unter den Linden.

Cheques and Postal Orders (on Chief Office, London) to be made payable to Mr. H. ALABASTER, 4, Ludgate Hill E.C.

CHEAP PRODUCTION.

IF we assume that the engineers' strike is now practically over, the best thing to be done is to push forward their rapid and well-paid re-employment as quickly as possible. Six months of idleness is in itself demoralising, and the men have gone through quite sufficient hardships, on the whole, fairly peacefully, to forbid any desire to extend further the sharp lesson of defeat. Now is the time, when they are thoroughly beaten, for the employers to step forward and drive home the arguments of the past half-year by deeds. They have the power in their hands to insist on better and more honest service. It is their duty to do it, and to do it so thoroughly that the men will assist to get back some of our lost trade. If this be done, there is good reason to suppose the country will be almost over-crowded with work. This will mean good wages, and, if this time of better wages arrives quickly, the men will learn, before they have become powerful enough to again indulge in skulking, that the system of work pays them better than the system of idling. As soon as they learn this lesson, the occupation of the agitator, who has lived on the doctrine of restriction and harassment, will have gone. Coming out as victors from the struggle, the employers have the right to insist on work being done for money paid, but they are equally bound to see to their own duties. Improved machinery and shop methods and an abandonment of all *laissez faire* notions must be faced. It is important that no loophole be left for the arrows of trades union criticism. Trades unionism is chameleon-like in its colours, and changes rapidly in its methods of attack. Unable to compel employers to its final outrageous demands for the maximum of wages for a minimum of work, it is by no means unlikely that future attempts at interference will be in the very direction the employers have practically been inviting it. Realising that the game of restriction is up, and perhaps having absorbed some of the scathing criticisms which have been levelled against unionism, as it has become, the leaders of reconstituted unionism may profess a willingness to increase output. They may make demands for men to attend several machines, and may lodge complaints as to the non-efficiency of old plant, and in various ways assume a virtue they do not feel, or have only lately acquired. Should events prove that the employers really have obtained the mastery, a very serious responsibility will be with them. In their hands lies the future of English trade. Their own weak concessions to the galling tyranny of trades unionism have done already much irreparable damage. True, the first offender has been unionism, and the employers perhaps did not foresee the result of their concessions; but *facile descensus averni*, and in this case the bottom has fortunately been reached the more quickly at the hands of Mr. Barnes than in milder hands. Great ends are sometimes accomplished by unworthy and unintentional means, and, it may be, Mr. Barnes has wrought better than he knew, for it is through him the end has come. Assuming, then, that further opposition to improved tools will now cease, English engineering firms are likely to require many new tools. For a time the Americans and their German copyists will profit, but English toolmakers, also released from bondage, should be prepared to meet the demand. Manufacturing engineering cannot be carried on with a general engineer's tools. It demands special tools and sub-division of operations.

It seems to be an axiom of repetition work that the greater the number of hands through which a piece is passed, the cheaper will be its production cost, for each hand performs a distinct operation, and does it quickly as the result of practice. What is known as the American method is but this. We question if, when Mr. Burns called for American methods, he really knew just what it was he was demanding. The so-called American methods are simply the methods of many of our free English shops. We know several such, and we have recently compared the prices and discounts of one such shop with the best German shop doing similar work. The German prices are 50 per cent. higher. This shows what can be done in England, where men and masters work together. Could he but see it, the present is Mr. Barnes's great opportunity. He is an adept at shunting issues. He may now turn about face, and claim to have started the present quarrel as a last resource to compel employers to advance, all other methods failing. His friend Burns has given him the cue. It will be easy to follow it, especially as it would afford an opportunity of worrying employers to buy new tools, and the employers will have to do so, and many of them are only waiting to do so until they can be assured of the power to work them up to their limits. Nor could employers complain at such new attitude on the part of unionism. We believe it is found in America, as well as in free English shops, that men push for the latest new appliances. Pushing tools up to their maximum production wears them out more quickly, but labour is a far bigger item than tools, and the time spent in taking care of a tool by easy work would pay for a new and improved tool very quickly.

It would just suit the executive of the A.S.E. to pose as the upholders of improved methods, and to claim for their past conduct a hidden spring of action in a desperate resolve to compel employers to bring themselves into line with new methods. This would be a repetition of the dishing of the Whigs which stirred political circles some years back. There is no such militant saint as a converted sinner, and trades unionism in a new guise of pushfulness would, indeed, be a refreshing and wholesome sight, and might, indeed, constitute a form of interference that would be not unwelcome. Certain American experience with English workmen, who were free to do as they wished in the way of pushing work, showed us some time ago that a certain manufactory, with English skilled men, could beat out of the field the other works in the same trade. There is value in skill and long practice, and in manufacturing engineering there is work which the labourer and the apprentice can do well enough on automatic machinery, but there is a field beyond their scope which will always require skill and superior intelligence. There are so many articles now imported from abroad simply because of the half-hearted manner of working in England, that to supply these goods alone will absorb all our surplus labour before very long. In the interim we fear that the men, who must remain for some time out of work before they can be reinstated, will be exposed to great hardship. The employers have been training others to fill their places, and have now got the very class, at the possession of which Barnes so girds. But it is to him that this new batch of men is due. He has been the kind giver. He also, and in referring to him we mean, of course, the policy of which he is the willing or unwilling mouthpiece, has been the destroyer of the union tyranny, and from him will probably date the new and improved condition of the engineering trades of Great Britain. It is possible—we think probable—that the strike has been a blessing in disguise. It need not have happened but for the complete tangle into which trades unionism has landed everyone. Out of the clearance it has made it is everybody's duty to see that the new buildings shall be on the new plan. As with the great City fire, we ought not to rebuild only, but to remodel.

Photo-Electric Phenomena.

About three years ago we described a form of electrode considerably more sensitive to light than any employed by previous investigators up to that time, and gave a few details of its construction. This electrode was described by H. Luggin, who contributed a paper on it to the *Zeitschrift für Physikalische Chemie*, Vol 14, pages 385—393. The electrode consisted of a platinum plate covered with bromide of silver, and, when used, is paired with a similarly coated silver electrode in a decinormal solution of potassium bromide. The rise of potential is determined by a quadrant electrometer, and, in some experiments, exposure to diffused daylight caused an increase of potential of 0·42 volt. The experiments show that when illuminated by a weak light, the rate of rise of potential is uniform and represented by a straight line until a maximum value is reached, after which it remains constant, or may fall slightly. With a stronger light the rate of increase is more rapid, but the final value is not greater; the rate, however, is not directly proportional to the intensity of the light, but is proportionately less than for weak lights, whilst it is also lowered by previous exposure to powerful light. Continuous and intermittent lights of the same mean intensity appear to have the same effect. The sensitiveness of the plate, however, does not remain constant, but, even after long rests, very different potential increases are obtained with the same light. Since the end of 1894, when Luggin first began to make experiments with this form of electrode, he has been carrying on the investigation with a sensitive electrode similar to that which we have described, but which could be raised to any definite potential above that of the liquid, and he describes his new results in the *Zeitschrift für Physikalische Chemie*, 1897, Vol. 23, pages 577—635. The current produced, or the photo-current, was measured, and it was found that an intimate connection exists between the strength of the photo-current and the depth of the darkening of the sensitive electrode. As the potential of the electrode is increased, however, the photo-current decreases; and ultimately a potential is reached where the current becomes zero, and, by increased exposure, may pass over to a current of opposite sign. Where the action of the current is to remove the halogen, and hence cause darkening of the electrode, the current is called normal or positive, currents which act in the reverse sense being known as solarisation current, and experiments show that both kinds of current may be produced with the same electrode, according to its potential and the light intensity. The solarisation current, in the case of silver chloride electrodes, more readily occurs with yellow light, whilst, on the other hand, blue light favours the production of the normal current, which, in contradistinction to the solarisation current, is coterminous with the exposure. The potential at which no normal current is produced is known as the equilibrium potential, and a linear equation is found to hold for the relation of the photo-current to the defect from the equilibrium potential, and in the equation the constant is probably dependent on the dissociation of the silver salt. Luggin endeavours to connect these results with the purely photographic phenomena, and considers that solarisation appearances are intimately and casually connected with the solarisation current, and, at any rate, with printing out papers the connection between the photo-electric and photographic phenomena is in the author's opinion established. The applicability of the halogen salts appears also to be connected with the value of the equilibrium potential, and the author finally discusses at some length the production of images by development.

SOME NOTES ON SINGLE-PHASE MOTORS.

By A. C. EBORALL.

(*Continued from page* 32.)

The stationary field magnet is of the ordinary multipolar form with inwardly radiating poles, the number of these being determined by the desired motor speed and frequency of supply. It is built up of sheet iron stampings bolted together and to a cast-iron frame work and bed-plate. The magnet poles have two windings; one, a thick winding of few turns, and used only at starting, the other a winding of smaller section wire and many turns, which is used when the motor is running synchronously. The armature is built up of core discs of the shape shown in fig. 3, and also has two windings. One, used at starting only, is an ordinary distributed drum winding wound in the slots, and connected to a commutator in the usual way; the other is a concentrated winding with flat rectangular coils wound in the holes, the coils being connected up in series, with the free ends connected to a pair of slip rings on the end of the shaft remote from the commutator. The number of these flat coils is equal to the number of magnet poles, and the number of slots for the starting winding is determined solely from considerations of sparking, &c. The third slip ring seen in the diagram has nothing to do with the action of the motor; inside it is a centrifugal device, which makes contact with the ring at a synchronous speed, causing a pilot lamp mounted near the motor to light up.

The starting of this motor is as follows:—A choking coil or resistance is inserted in the starting circuit, as shown, and the switch thrown over to the "start" position. The motor immediately begins to run up as an ordinary series motor, and at a synchronous speed the lamp lights up. Directly this happens the switch is put over, which puts the slip rings into direct connection with the supply mains, and the brushes on the commutator into connection with the fine wire winding of the fields, so that now the motor is running as a self-exciting reversed alternator. The number of windings on the choking coil, or the magnitude of the starting resistance, is determined by the torque required, the motor starting with any torque if enough current is given to it.

Through the courtesy of Messrs. Bergtheil & Young (London), who are the English agents for this motor, the present writer has been enabled to make some tests of its performance. These, though only of a workshop nature, came out very well indeed.

The 2½ H.P. motor provided was built for 100 volts, 133 ~, and ran at 1,500 revolutions per minute on the 100 ~ testing circuit. It started immediately without any trouble whatever at any load, and with a reasonable current consumption, this being about twice the full load current when exerting the full load torque. The efficiency above half load was high, averaging 70 per cent. The power factor of these motors for any particular load depends, to a large extent, on the field excitation, that is, on the magnitude of the resistance in series with the fields. With the resistance adjusted to give the best effect for three-quarter load, the power factor at this load came out at approximately 73 per cent., diminishing slightly as the loading was increased.

There was absolutely no sparking at the commutator either at starting or running, the carbon brushes remaining throughout in a fixed position. As a matter of fact, they are not mounted on a rocker, the holders being fixed.

This motor has, then, the following good points:—

1. It starts well on any load without any external complications, and without an excessive current consumption.
2. It stands considerable overload.
3. The power factor and efficiency are high.
4. Its speed is absolutely constant, with constant frequency.

Its defects are—

1. It is somewhat expensive.
2. It is noisy when running light or underloaded.
3. Its design is necessarily rather straggling.
4. The centrifugal service might fail to act, in which case the armature stands a chance of flying to pieces in the hands of a careless workman.
5. The "no load" current is rather high.

Owing to the absence of sparking and to the fixed brushes, the presence of the commutator is hardly felt. In the writer's opinion, the motor could be improved by diminishing the air-gap, this being somewhat excessive in the examples that have come under his notice. The superiority of these motors over others of similar design seems to lie in the fact that the armature and field windings are so adjusted that the maximum magnetic effects of each occur at the right times.

It is evident that such a motor would make a good rotary converter, continuous current being tapped off the commutator when the motor was running on alternate current mains, or *vice versa*.

II.—Alternating Magnetic Field Motors.

Owing to the fact that the direction of rotation of any ordinary direct current motor is the same irrespective of the direction of the current supplied to it, early attempts were made to adapt it for use with an alternating current by laminating the fields. But this simple modification is not enough in itself, the crude form having many serious faults, the chief of them being—

1. Low efficiency, chiefly due to the hysteresis and eddy current losses.
2. Large "no load" current, and very low power factor, due to the nature of the windings, large air-gap necessary on account of armature reaction, and to the very considerable magnetic leakage.
3. The heavy sparking, especially at starting and overloads, and which is due to the fact that as each armature coil is in turn short-circuited by a brush, it becomes the seat of very heavy induced currents, these reacting on the magnets, and causing great heating and sparking.
4. Low weight efficiency, which is caused by the impedance of the motor circuits not allowing sufficient current to get through, and principally due to the self-induction of the magnets; and in the case of shunt motors, it is found that besides this last difficulty, there are great differences of phase between field and armature currents, causing the maximum magnetic effects of each to occur at different intervals of time, this want of coincidence greatly diminishing the torque.

These inherent defects have not yet been overcome, and motors of this class are quite unsuitable for anything but the smallest work. Many attempts have been made to improve them, none of which have been successful up to the present. Thus to help bring the armature and field currents more into phase, condensers have been put in these circuits (Stanley and Kelly), or short-circuited demagnetising coils have been sunk in the pole-pieces (Stanley and Kelly). To minimise the sparking, double wound armatures have been used, so arranged that a coil is never actually short-circuited by a brush, this latter merely changing the resistance of the armature during rotation, according as one winding, or the two in parallel, came under it (Hutin and Leblanc).

The crux of the whole question is really the frequency; if this be lowered sufficiently (say to 15—20 ~), all the above defects are greatly minimised, and there is no reason why such motors should not be commercially successful.

III.—Induction Motors.

Single-phase motors of the induction type probably constitute 75 per cent. of all the single-phase motors running on the Continent at the present time, and are made by all the important firms, such as Brown, Boveri & Co., the Oerlikon Company, Kolben & Co., the A.E.G. (Berlin), and Siemens and Halske. They operate as follows:—

Let fig. 4 represent the elements of a single-phase induction motor. It consists of a stationary inducing system *or stator*, being built up of stampings with holes or slots stamped round the inner periphery, and a similarly constructed *rotor*, in the windings of which currents are induced. The stator winding consists of flat coils, wound in the holes in a manner to be more particularly described later, the number of coils depending on the number of poles required, these being given by the speed. The rotor winding is simply a number of copper bars, short-circuited at each end by means of copper rings. Now suppose the stator windings to be connected to the supply mains. An alternating multipolar magnetic field is produced round the stator, oscillating with the frequency of the supply current, and whose tendency is to produce an equal torque on the rotor in opposite directions, and hence no rotation occurs. But if the rotor is given a start in either direction, and its speed gradually increased by some external means, a point is soon reached when the rotor will go on revolving by itself with increasing speed, until nearly synchronous rotation is attained. Load can now be put on the motor, when the speed will drop slightly, just as in the case of a polyphase motor, but to a somewhat larger extent. This "slip" of the rotor increases from a minimum at no load up to a certain point, generally about twice full

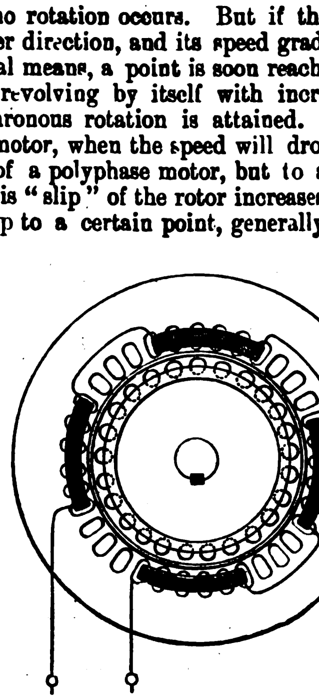

Fig. 4.—Simple Induction Motor.

load, when the motor runs out of step, and must be restarted. The slip is the frequency of the rotor currents, and hence the effect of loading the motor is to cause such a slip as will increase the rotor currents by such an amount as will correspond to the necessary increase of torque.

The theory of the single-phase induction motor is necessarily somewhat complicated. The best treatment of the subject is that of the late Prof. Ferraris, it consisting in considering magnetic fields as vector quantities, capable of being combined as ordinary vectors. According to this, an oscillating magnetic field may be considered as being the resultant of two rotating fields of constant and equal strength, and rotating in opposite directions with the same frequency as that of the oscillating field. If the oscillating field follows a sine law, then such a field of maximum strength N, and with p poles, oscillating with frequency n, may be represented by two sinusoidal rotary fields of p poles and maximum strength $\frac{N}{2}$, the one rotating forward, and the other backwards, with a speed of $\frac{n}{2p}$ revolutions per second.

It is not difficult to show that any distribution of field of p poles may be decomposed into a number of multipolar sinusoidal fields. There would be (1) a fundamental sinusoidal field of maximum strength N_1 of p poles, (2) a first harmonic sinusoidal field of maximum strength N_2 with $2p$ poles, (3) a second harmonic sinusoidal field of maximum strength N_3 with $3p$ poles, and so on. Hence it follows that any oscillating field, such as might be produced in any form of single-phase induction motor whatever, may be decomposed into a number of multipolar sinusoidal fields of different maximum values with different numbers of poles, and rotating, some forward, some backward, with velocities inversely proportional to the number of poles.

It is to the forward rotating field or fields that the rotation of the motor of a single-phase motor is due; this forward rotating field acting on the rotor in every respect just as the rotating field produced by a two or three-phase current acts in multiphase motors. That is to say, the torque on the rotor is due to the fact that the rotor field produced by the induced rotor currents follows up the forward rotating field, never quite catching it up, but having a certain slip with regard to it, this slip, as previously pointed out, increasing with the load, and is, of course, equal to the difference between the frequencies of the forward rotating field (frequency of the supply current), and the rotating field of the motor $\left(\text{which is } \frac{\text{number of motor poles}}{2} \times \frac{\text{revolutions per minute of rotor}}{60}\right)$.

Now this mode of treatment readily lends itself to the solution of the usual problems connected with induction motors. Some years ago it was shown by Mr. M. B. Field that it could be extended to the ordinary Kapp diagram for multiphase motors,* and that by constructing such a diagram with the forward and backward fields, the performance of the single-phase induction motor in regard to efficiency, power-factor, torque, &c., can be predicted if certain constants are known. The present writer hopes shortly to be able to go fully into this method of Mr. Field's in another place, as it should prove of considerable value to all those having an interest in this class of alternate current plant.

rection made. The top right-hand switch blade marked * was omitted from last week's block.—Eds. Elec. Rev.

SHIELDED CONDUCTORS.

By W. A. PRICE.

(*Concluded from page 63.*)

Mr. Mordey's suggested explanation of Prof. du Bois' observation published in the *Phil. Mag.* for December† is difficult to understand. He attributes it to the fact that a ring solenoid is equivalent magnetically, so far as the external field is concerned, to a single turn laid along the circle that forms the axis of the helix, but how such a ring can experience a side thrust in a magnetic field is not easy to see. One would expect only a tendency to turn into a plane perpendicular to the field.

Mr. James Russell describes also a number of interesting experiments on the forces exerted on a conductor carrying current in a magnetic field, when shielded by an iron cylinder. In one of these an iron tube is placed in an uniform magnetic field perpendicular to the tube, and a conductor is placed in the axis of the tube. On starting a current in the conductor, the iron shield tends to move sideways, *i.e.*, at right angles to the field and to its own length, while the conductor experiences little or no force. Considered in connection with the action on the magnetised ring (fig. 4) the result seems paradoxical, *i.e.*, if this action be what we suppose, and Prof. du Bois is mistaken; for the effect of the current on the iron tube is to magnetise it circularly, and to produce motion sideways, while no such motion occurs with a permanent ring magnet of the same form.

* See Kapp's "Power Transmission," page 346.

† See Electrical Review, January 7th, 1898.

The explanation lies in the action of the current on the field outside of the iron tube, which is distorted by the current exactly as if the iron shield were absent, and is not affected by the circular distribution in the ring itself. In fact, though the iron tube shields the conductor inside it from the action of the outside field, and prevents any force from acting on it, it does not shield the outside field from the action of the current in the conductor. It seems possible that Prof. du Bois, in his experiment on the magnetised ring, may have led his current in such a way as to distort the field, and so produce the action on the ring, an action which would be more intense if the ring were not permanently magnetised, and more permeable.

Fig. 5 shows the character of the distribution of the field

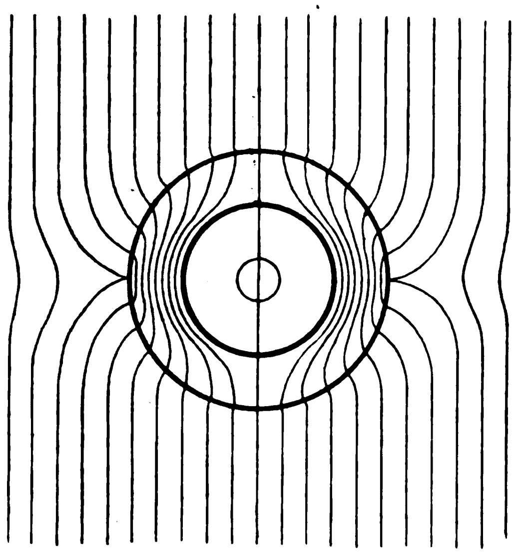

Fig. 5.

when no current is passing in the conductor. It is, of course, similar to fig. 3. Fig. 6 shows the field when a current is passing, and the field is disturbed outside the shield, tending to move it in the direction of the arrow. Comparisons of figs. 4 and 6 shows the difference between the conditions of

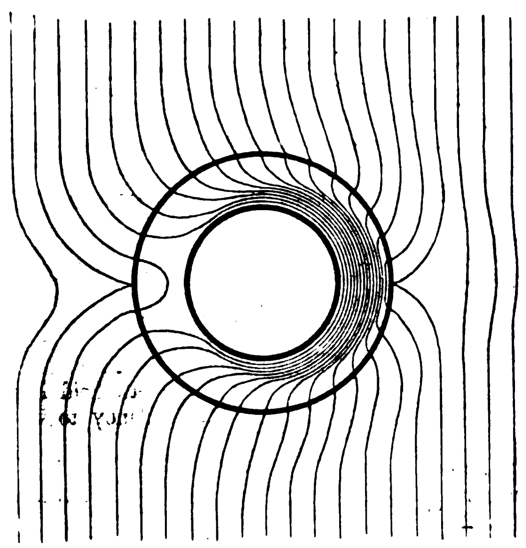

Fig. 6.

Mr. Russell's experiment and the one we understand Prof. du Bois to describe.

Another point requires notice. A law of refrangibility has been repeatedly referred to, viz., that the ratio of the tangents of the angles made by a line of magnetic flux with the normals on two sides of a surface separating two different media is equal to the ratio of their permeabilities. This only applies when neither medium is coercive, and the field of magnetic force is continuous at the surface in question; *e.g.*, suppose in diagram fig. 7, A A, B B, are infinite plane current sheets, A A coming up, B B flowing down normally to the paper. The space between A A, B B, is an uniform magnetic field in the direction of the arrow. Now, if the whole be placed in an uniform field perpendicular to the sheets, the lines of flow will take the direction shown in

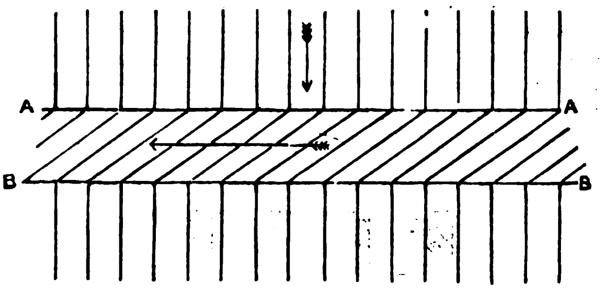

Fig. 7.

the figure, each of them bending sharply where they cross the current sheets, though the whole space is equally permeable.

So where lines of flow enter hard magnetised steel the law does not apply, and since all iron is coercive, and other materials have practically the same permeability, the law is little more than a guide in drawing freehand certain classes of diagrams.

It is not suggested that the writers who have referred to this law are not familiar with its limitations, but when laws are formally stated one is apt to think the statement is also complete.

I am tempted to suggest another paradox. A space is enclosed by a shield formed of bar magnets placed side by side with all their north poles outside, and all their south poles inside. There can be no flux, and they consequently cease to be magnets.

For a simple case, consider the space enclosed between two infinite plane magnetic shells (fig. 8). Along N N, N N,

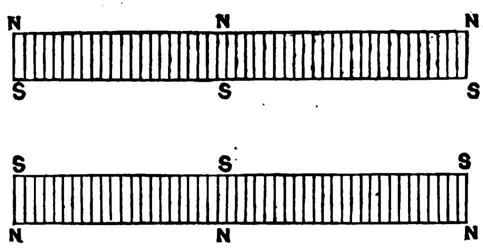

Fig. 8.

are north poles, and along S S, S S, south poles, the shells being made of small bar magnets placed side by side. There is no magnetic field anywhere. Have the bars ceased to be magnets?

WINDINGS OF POLYPHASE ARMATURES.*

By J. P. STONE.

With the introduction of polyphase apparatus, a number of different windings have necessarily been developed, although all of them have the same general features. Since they are slightly different, it may be thought that they are of essentially different character. It is the object of this paper to

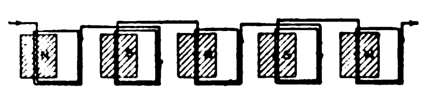

Fig. 1.—Single-Phase Winding.

illustrate how these windings are made, and to show that it is rather unessential what type of connections are used as far as behaviour and output of machines is concerned.

* *American Electrician.*

The single-phase winding in its simplest form consists of a number of coils connected up so as to give alternate polarity all round the surface of the armature. Assume that an alternator has 10 poles, we could thus have a winding consisting of 10 coils, as illustrated in fig. 1, each coil connected in reverse direction in regard to the preceding; or we could have a winding as illustrated in fig. 2, consisting of five coils, which coils are connected so as to give the same polarity, but separated from each other by the pitch of the poles—that is, by the distance between two adjacent poles.

Necessarily, if all coils are connected so as to give the

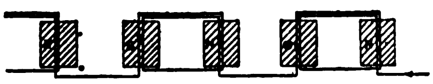

Fig. 2.—Single-Phase Winding.

same polarity, the space between the coils will have the opposite polarity to that given by current passing through the coil.

A two-phase generator could be made from a single-phase generator by adding a set of new coils placed midway between the first coils and wound in identically the same way as the first winding. Since the distance in phase

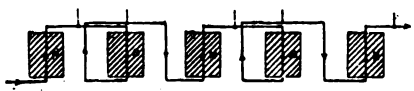

Fig. 3.—Two-Phase Winding.

between two adjacent poles is 180°, it is evident that the beginnings of the two independent windings will be 90° apart; thus, if the two windings have the same number of turns, the generator will have two independent sources of power of same magnitude, one displaced 90° from the other, that is, we have a two-phase generator with independent

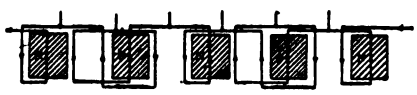

Fig. 4.—Three-Phase Winding.

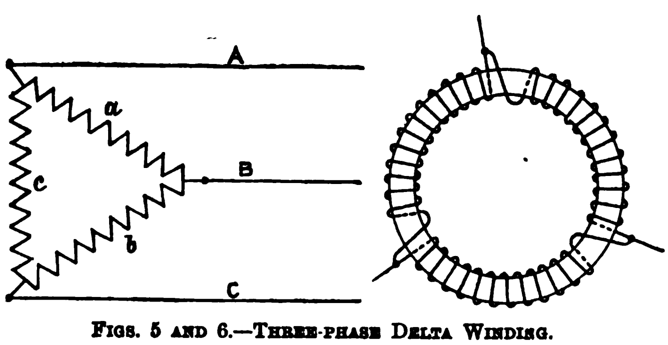
windings. Such a machine would then, of course, have four collector rings, two for each of the windings. By connecting two adjacent collector rings together, a two-phase relation still remains, and we have a two-phase machine with interlinked windings.

The same results can also be obtained from a distributed single-phase winding by proper connections, provided that the number of coils between each pair of poles is divisible by two. Such a winding is illustrated in fig. 3, and is, as can be

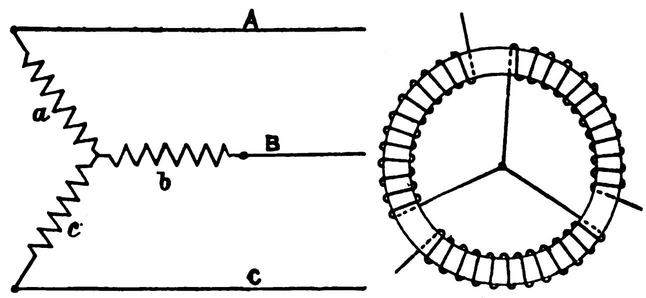


Figs. 5 and 6.—Three-phase Delta Winding.

seen, essentially a direct-current winding in which four taps are taken out to four collector rings (bipolar machine). Thus no new features in winding are introduced in making a two-phase generator.

A three-phase generator is made on essentially the same plan. It consists primarily of three independent single-phase windings, such as are described in fig. 1 or 2, each starting 120° in phase from the preceding; that is, since the distance between two pairs of poles is 360°, if the first winding starts midway under one pole, the second winding, wound identical with the first should start at one-third of the distance between two poles and the third at two-thirds the distance between the poles. Thus we see how a three-phase generator can be wound. If these circuits are not joined, six collector rings are necessary, two for each phase. Since, however, each winding has a point of equal potential with either of the other two, that point can be connected on all three.

That is one end of each of their windings is brought to a



Figs. 7 and 8.—Three-phase Y-winding.

common junction, from which they branch out starwise, and the remaining ends are connected to the three line wires. The three lines thus serve in turn as outgoing and return circuits, the maximum current shifting from one to the other in succession. We thus obtain a Y-connected machine which necessitates three collector rings only.

Similar to what was stated regarding the two-phase winding, the three-phase winding can be obtained from the distributed single-phase winding by tapping the winding at suitable points; that is, points differing in phase by 120°. Such a winding is illustrated in fig. 6, and is called the delta winding. This is also shown diagrammatically in fig. 5. Here the coils form a closed mesh, the six terminals being united two and two, the lines being connected to the windings at the three points of junction, forming a triangle. In order to make such connections, however, it is, of course, necessary that the single-phase winding should have at least three slots per pole and phase (for a full pitch winding) or a multiple of 3. Such a winding is illustrated in fig. 4.

The three-phase windings can also be shown as simple Gramme windings, having only one coil per phase, as in figs. 6 and 8, which are shown delta and Y-connected, respectively. Thus it will be seen that a direct-current winding may be connected into a three-phase delta-connected winding by tapping it at equidistant points, the number of leads being governed by the number of poles.

Denoting the E.M.F. induced in each winding by E, it is evident that the E.M.F. between the lines in a delta-connected armature must be E, since the lines are connected directly to the ends of the winding. In a Y-connected armature, however, one end of each of the three windings are connected together, and the other three ends are connected to the lines, as in fig. 7; but since the E.M.Fs. induced in each winding are not in phase with each other, the E.M.F. at the terminals is not the sum of the E.M.Fs. induced in each winding; that is, it is not 2 E, but is the geometrical sum of the E.M.Fs. in the two phases—that is $E \sqrt{3}$.

The output of a polyphase generator is that of the sum of each individual phase; that is, denoting the current in each wire in a Y-connected motor by C, and the E.M.F. induced in each phase as before, by E, the power of the three-phase generator is $3 \times C\,E$. Since, however, the E.M.F. between the lines is $\sqrt{3}$ times the E.M.F. per phase—that is $E \times \sqrt{3}$—we find that the power of a three-phase generator expressed by the line E.M.F. and line current must be $\sqrt{3} \times C_1 \times E_1$, where E_1 and C_1 and the E.M.Fs. and the currents, respectively, between the lines and in the lines. In a delta-wound motor, in the same manner, we find the power delivered to be expressed by the same equation.

(*To be continued.*)

THE TRANSFORMATION OF ENERGY IN THE ELECTRIC ARC.

The mechanism of the conversion of electric energy into heat in the electric arc still evades the inquiries of experimenters, but papers are from time to time published dealing with the subject, and new suggestions made, and new conclusions reached, without any conspicuous approach to an explanation of what occurs. Mrs. Ayrton's laborious and systematic observations are in recent years the most important of these contributions. Of course, "explanation" in such a case as this means no more than that the phenomena are shown to be subject to laws and conditions which are ascertained and well recognised in other cases, even though the mode of action in the latter may be quite obscure. The reference of the planetary motions, and the weight of terrestrial bodies, to one law of the attraction of gravitation, is called an explanation of these phenomena, though the mode of attraction is not less obscure than the phenomena it explains, and the very idea of action at a distance may be abandoned as a misleading fiction. Following a course of this kind, one experimenter after another has attempted to find laws for the behaviour of the electric current in the arc, similar to those which it obeys in a metallic conductor.

Electricity flowing through a metallic conductor generates heat at a rate proportional to the square of the current, and the independence of that coefficient, which is called the resistance, of the amount of current passing, is so conspicuous a property of metals and their alloys that it seems to indicate some marked characteristic in the mechanism of their conduction. So when a current of electricity flows through a junction of two different metals heat is developed, or absorbed, at a rate directly proportional to the current; and here again the coefficient involved, viz., the electromotive force of contact, is a physical constant not less significant than the resistance. The molecular structure of metals is unaltered by the passage of the current, and no transfer of matter takes place.

This last property clearly differentiates the mode of conduction by metallic conductors from that by the arc, where disruption and transfer of matter occur. The *primâ facie* improbability is very great that conduction by the arc is regulated by laws similar to the peculiarly exact and simple ones which apply to metallic conductors. All attempts to represent the heat developed in the arc, as due to a resistance and a back E.M.F.—or, in other words, to express it as the sum of two terms containing the first and second powers of the current respectively—have been futile, and it appears unwise to persist in attacking the question on these or similar lines.

If the arc consists of molecules, torn from the positive carbon, employed in the incessant to and fro bombardment of the poles, carrying positive charges to the negative, and negative charges to the positive carbon, the mode of transference of the charges is by convection and not by conduction; and an attempt to represent the action in terms of the ideas used for metallic conduction, is analogous to an attempt to enter the statistics of a town supply by water carts on printed forms arranged for the data of a pipe supply.

An observation that under certain circumstances an increase of current in the arc is accompanied by a diminished potential difference between the carbons led the observer, drawing too closely the analogies with metallic conduction, to the absurd conclusion that the arc possesses negative resistance. No portion of the heat generated in the arc has been traced to a distinct cause involving transformation of energy proportional to the square of the current; and we have no ground for assigning resistance to the arc.

Prof. Fleming, in a letter to the *Electrician* of January 7th, considers the probability of the existence of a "counter electromotive force in the arc," and makes an interesting suggestion as to its possible source. It is not quite clear what idea is expressed by the words "counter electromotive force." They must mean something more than a means whereby electrical energy is converted into heat in direct proportion to the current, and seem to imply that the action is reversible, and to some extent elastic, so as to produce an E.M.F. in the reverse sense, if only for a very short time, on the sudden cessation of the main current. Such an action has been looked for repeatedly in the arc, but never, we believe, detected. It occurs in every other case we can call to mind, to which the term "counter electromotive force" is applied. It is not obvious why it should be looked for in the arc at all. An elastic action implies a return from a more to a less strained condition, and if the energy in the arc is employed in the disruption and mutual bombardment of the carbons, no reversible effect is to be expected.

Prof. Fleming suggests that the current may generate heat in direct proportion to its amount when passing from a hot point to a cooler one in carbon vapour, by analogy with the Thomson effect in copper, or solid carbon; the existence of a difference of temperature in the carbon vapour being inferred from the difference of temperature in the carbon rods at the arc. The explanation requires carbon vapour and solid carbon to be in contact at two very different temperatures at the same pressure, and to have very different thermo-electric gradients; since if the gradients were the same, the total development of heat, by a Thomson effect, between the distant ends of the carbons, which are at the same temperature, would be zero. The latter condition may be satisfied: we have no knowledge of the matter; but it is hard to see how two very different temperatures can be found in a small body of vapour, presumably saturated. The existence in hot gases of an effect similar to the Thomson effect in solid conductors is only guessed at, but it offers an interesting subject for experiment. If this effect is found in carbon vapour, electromotive forces between the solid and gaseous carbon might exist at the contact surfaces, similar to the Peltier effect in metals, and the energy converted at those points might be expected, by analogy, to be considerably greater than that due to a difference in the thermo-electric gradients in the solid carbon, and in its vapour.

It may be observed here that the reduction in the potential difference of the carbons for a given current, by heating the negative carbon, is explained by the bombardment hypothesis, as well as by Prof. Fleming's.

Observations on the distribution of potential in the arc are difficult to interpret, but it appears that the difference of potential between the central part of the arc and the negative carbon is small or zero, and that the whole fall of potential in the arc takes place at or near the positive crater. At this point disruption of matter is taking place, and the generation of heat under these conditions and the generation of heat by a Peltier or Thomson effect, where no change occurs in the condition of the matter concerned, seem phenomena, *primâ facie*, to be placed in very different categories. It would seem that little assistance in this question is to be expected from analogies drawn with the phenomena of electric conduction in solids. The phenomena seem rather allied to those of discharges in rarified gases, and movements in electrolytic solutions.

CHEAP ELECTRICITY.

The presidential address of Mr. Raworth to the Northern Society of Electrical Engineers comes in for a good deal of satire from the *Engineer*, which is rather solemn in its treatment of most questions, and is very severe upon Mr. Raworth. Perhaps it is that the writer has a sneaking envy for the optimistic breeziness of Mr. Raworth. Our contemporary, however, cannot at all put up with such breeziness, which is even in parts of doubtful seemliness in its humour. The comparative absence of figures does not meet with approval. In a presidential address figures are not much wanted. Too many such addresses are but at best gracefully connected recapitulations of well-known facts.

It is with such few figures as were given that the *Engineer* falls foul. Mr. Raworth suggests a 50,000-H.P. power plant to earn £200,000 a year gross, or at the rate of £4 per H.P. We are asked to see how much each horse-power will cost. Coal will run to 3 lbs. per E.H.P., so that 1 ton would yield 750 H.P. hours, and a year of 7,300 hours—rather a long year, for it means 20 hours a day—will cost 9·73 tons of coal, or, say, 10 tons, costing £2 10s., which is too high a proportion of the selling price of current to warrant much hope of a profit after other expenses are paid. But after all, did Mr. Raworth mean days of 20 hours.

If not, and 10 hours' days were meant, the coal would be reduced to £1 5s.

The *Engineer* considers 5d. per unit as a low limit of price. Yet one London company is now offering current for power purposes at rates of as low as 2½d. per unit, so that there are those who consider 5d. an excessive price. The *Engineer* begs the question, when it cavils at the claim that electricity will be produced more cheaply than now. How can there be much reduction when dynamos already have an efficiency boasted of at 90, or even 98 per cent. Yet even the *Engineer* admits a possible cost so low as 1½d. per unit, with engine and dynamo alone. For ourselves, we look upon the future of electricity very hopefully. Its chief objection is its first cost of installation for small units. The rules and regulations, the claimed rights and arbitrary privileges of electrical supply companies, more than vie with any gas company. Especially is the power of cutting off supply without notice a clause which ought to be carefully considered. The small prospective consumer is apt to be scared off by the ponderosity of the demands upon him. True, he may be going to effect an economy by using electricity, yet, for all that, he does not relish being treated by a new electrical company as though they were conferring a huge favour on him by selling him current.

Electricity may not be so cheap as Mr. Raworth would make it out to be, but it will not be so dear as the *Engineer* would have us believe, but in either case the Leeds figures, which we publish in another part of this issue, are instructive. As we write we have in mind a works where steam is now the motive power, and is costing anywhere from £50 to £100 per annum. It costs this whether one or six machines are run. As a rule, one, and that the smallest, is the machine most run, and that only for half the day. At 6d. per unit, it ought not to cost above 6d. daily to run that machine, or, say, £8 annually. It is hardly likely that such a user would not gradually extend the system to all his machinery, besides becoming also a customer for light and even for heating. It is impossible to read what has been effected in electrical driving in America to perceive that it is in the electricity which is not used that the saving comes. It is the shaft that is not revolved, the boiler feed-pump stopped, the forge-fan which stands still when the work is on the anvil, the grindstone which stands when not being used, the long steam pipe not condensing steam, the oil, the belting, the waste, the dirt and inconvenience, it is all these negatives which show a commercial economy in expensive electricity. Doubtless Mr. Raworth sees this, and feels breezy about the prospects.

For large powers, we do not think it likely that electricity will be generated very far from the centres of coal production. Long distance transmission is not yet perfected, nor are line losses yet minimised. The use of gas engines with producer gas, or worked by the waste gases of huge blast furnaces, may change the whole condition of the industry. To use gas from a blast furnace demands a much smaller outlay than the preparation necessary to use a Niagara or a Foyers. Our contemporary is too apt to look on things as they are, in place of as they are becoming. It may not be wise to prophesy until we know, but the determination to have things as we wish them to be is almost akin to prophesy. Indeed, a clear perception of existing facts may warrant an expression of opinion that is not so much prophetic as far seeing.

AN ELECTRICAL HYPOTHESIS FOR THE SOLAR AND PLANETARY SYSTEMS, AND SOME OF THEIR ASSOCIATED PHENOMENON.

By DELTA.

When great astronomers so widely differ in their hypotheses to explain the solar and planetary systems as to lose their good manners—instance Lockyer's reflections on Huggins—the audacity of an outsider in suggesting an explanatory theory quite distinct from either that of the waste by combustion or the nebulæ or meteoric hypothesis, will perhaps be forgiven. Merely as highly speculative hypothesis, it may, perhaps, be considered as at least interesting if only from the evidence of coincidence and correlation collected to explain the effect of electricity in producing many of the phenemenon that cluster around a subject of surpassing grandeur.

It is usually accepted by both schools of solar explanation that the sun is in a state of magnificent conflagration,* and that there is by its assumed contraction †—or by its internal combustion—a gradual waste of energy proceeding, that will ultimately close the sun's glorious mission as a centre of light and heat.

It is also assumed that such is the inconceivable effect of combustion or contraction in luminous and heat-producing intensity, that both light and heat rays are transmitted to the glittering planetary and stellar elements suspended in celestial space, some of which are computed to be hundreds of millions of miles from the solar orb, the earth's distance from the sun being estimated to exceed 95,000,000 of miles. Now, anyone who, like the writer, has had great experience in the production of relatively enormous fusion temperatures, will know that although the luminosity resulting from masses of molten metal, such as very low carbon steel, will project a beam of light extending, under certain atmospheric conditions, over a distance of five miles; nevertheless the sensible heat transmitted to any body that chances to intercept such a luminous beam, will not be perceptibly felt at a distance of even, say, 50 yards.

So that if this ratio of as 50 is to $(1,760 \times 5)$ were applied to the proportion of heat and light transmitted from the assumed burning solar orb, no heat, sensible to human life, could possibly be transmitted through all the enormous gulf of space that divides our planet earth from the sun.

It was this *à priori* reasoning that led the writer to doubt the *rationale* of existing hypotheses presuming to explain the solar and planetary system, and the doubt found expression in a communication, published in a technical contemporary several years back. In this it was suggested that although light and heat of the earth had their origin in the sun, it was quite inconceivable to the writer that there could be a loss of energy and drop of potential, mile by mile of the 95,000,000 of luminous and thermal passage, through which the solar rays have to traverse before they reached the earth. On the contrary, it was suggested that there would be no loss of the energy (producing heat and light at the earth) between the outer fringes of the atmosphere (or photosphere, chromosphere, and corona) of the sun and the atmosphere of the earth or any other of the planetary or stellar bodies in the celestial space, and that only in proportion to the actual sum of luminous and thermal energy entering the planetary atmosphere, and also in some ratio depending upon the density of such atmosphere—was such energy expended in the production of light and heat. To assume that light and heat is uselessly expended all through the distance intervening between the sun and the planets appeared to be quite inconsistent with any rational conception of the laws of the conservation of energy, and the hypothesis that all the enormous heat waste that must as a consequence follow the acceptance of such a theory, could be derived from the assumed burning out or contraction of the sun, or of the planets, appeared to the writer quite inconceivable and utterly impossible.

There are many other objections to the acceptance of the existing theory; for instance, it would involve the assumption that beams of light are emanating from the solar orb to all the planets, and these beams would be seen traversing the dark interplanetary space, exactly as we see the beams of an arc light projected from the lantern of a lighthouse at sea, even when the source of the light itself cannot be seen. The author's audacious experiment of forming an alternate and entirely electrical hypothesis is based on the suggestion already described, to the effect that there is *no loss of energy* between the solar and planetary atmospheres; the suggestion is amplified and extended as follows:—

(*a*) The solar orb is accepted as constituting the great distributing centre of light and heat, which is, however, not only generated in an *electrical* form, but is transmitted to the planetary and other celestial bodies electrically, and in *no* other kind of energy.

* The sun is assumed to be gradually burning itself up, but as such a combustion would involve a supply of oxygen, it is difficult to accept this theory as in any degree rational.

† There is no absolute proof of any reduction of the bulk of the sun's sphere.

(*b*) The entire interplanetary and interstellar or celestial space may be considered to be an electrical ocean of assumed low intensity potential (and constituting a magnetic field), permitting electrical currents of assumed high intensity and frequency to flow to all the planetary bodies in direct lines from the great central solar generating station.

(*c*) The planetary and stellar spherical bodies are assumed to be secondary conductors of a system in which the solar orb is the primary.

(*d*) The secondary spherical conductors are of a polar character.

(*e*) The planetary spheres absorb at their surfaces opposite the sun or facing the direction of the electrical flow the positive and high intensity electrical energy projected from the sun across the celestial interplanetary ocean of low electrical intensity. The surfaces of the planets that in their rotation are illuminated are those that absorb the high intensity electrical energy.

(*f*) The surfaces of the spheres away from the sun give up again the electrical energy (transformed down to low intensity) to the celestial ocean of low electrical energy of low intensity, the electrical ocean acting as the agent of compensation in the cycle of the conservation of energy. The surfaces of the planets that in their rotation are in darkness, are those from which the electrical energy is *given up* by the *planets* to the electrical ocean.

(*g*) The low intensity electrical energy of the celestial electrical ocean is, by the law of compensation, constantly being absorbed by the sun, or in proportion to the electrical energy of high intensity that is being projected by the sun to the different spherical, planetary, stellar and other conductors that dot the great immensity of the celestial electrical ocean.

Now let us consider the effect of this hypothetical cycle of electrical energy movement in its effect on the planetary bodies and on the sun.

Both the sun and the planets are, and with good reason, assumed to possess atmospheres or gaseous envelopes of varying density.

The electrical energy of high intensity or frequency flowing from the sun will be met, first, by the resistance set up by its photosphere or corona (which are merely atmospherical envelopes of varying density). The resistance set up by the sun's atmosphere promotes the grandly resplendent luminosity of the solar orb. Immediately the high intensity current passes over the extreme fringe of the resisting solar corona, or outer solar atmosphere, it flows unrestrictedly across the low potential electrical ocean, until it meets with the atmosphere of the planets, or other celestial bodies, stellar and otherwise.

From the time it leaves the solar atmosphere to the time of meeting that of the planets, no energy is assumed to be expended, and the electrical ocean is consequently neither illuminated nor heated,* and two conditions therefore follow the acceptance of this essential condition: the interplanetary space, or electrical ocean of low intensity is non-luminous, and is of low temperature†. Were it not so, and if the interplanetary space offered resistance to the flow of electrical energy, there would be a solar beam of light, and we should see such effects in vivid lines of light stretching from the sun to the planetary and stellar bodies.

(*h*) As soon as the electrical currents of high intensity enter the earth's atmosphere, *luminosity is produced*, and of an intensity and colour depending upon and controlled by the density and chemical character of such atmosphere.

* Exact evidence.—On July 29th, 1878, and under satisfactory conditions, there was observed in North America a total eclipse of exceptional duration. Although no exceptional prominences were visible, the corona had a pair of enormous equatorial streamers that stretched east and west of the sun. They were best seen with the naked eye.

The solar poles were also equipped with straight *electric-looking brushes of luminous rays*. The sun at this time of the observation was in a state of profound tranquility.

Grooch noticed in 1867 the same equatorial extensions and polar electric-looking brushes of light.

† So from the extremely low freezing temperature of the interplanetary space it is very necessary to say that the Cirrus clouds, only some 5½ miles distant from the earth's surface, are composed of snow particles.

Comets have been discovered coated with ice, and in some instances internally frozen, although the outer surface had been heated up by their frictional contact with the atmosphere when travelling at a terrific velocity.

(*i*) Associated with the production of luminous energy there is the generation of heat, and of actinic or chemically stimulating energy, both effects depending upon the density and chemical character of the atmosphere.

Thus the surfaces of the earth, and those of other planets that absorb by their *vis-à-vis* position to the sun the high intensity electric currents, are covered with an illuminated atmosphere, the luminousness of which is dependent upon the density of the atmosphere at any point.

For instance, the equator is in direct line, and consequently the atmosphere at this point offers less length of passage to the flow of the electrical current, and the luminous and thermal production effect is thus *pro tanto* more concentrated than in the distances away from the line of least resistance.

The tendency of electrical currents to flow along lines of least resistance will have, in its effect on the direction of the current, the influence that refraction is assumed to have upon the direction of light rays.

The high intensity electrical energy, lessened somewhat by expenditure in producing heat, light, and chemical effects, flows into the earth,* and it is then by some internal and intermolecular influence, and perhaps by resistance culminating in internal fusion, converted into low potential, and in this form it flows to the opposite surface to that which it entered, or to the poles, and finally flows from the dark surface of the earth into the great compensating element, the electrical ocean of low intensity. Owing to its low and partly-expended intensity, it is incapable of elevating the resisting atmosphere to a condition of a luminosity sensible to the human retina, hence the phenomenon of night.

The expenditure of electrical energy is assumed to be exactly compensated for by thermo-dynamic electrical influences, by electro-chemical effects, and by thermo-electrical influences. The low intensity electrical ocean entirely surrounds the planetary and stellar bodies, so that any cause effecting a supply of the primary energy is absorbed into and assists in compensating for its expenditure.

The degree of the luminous effect is directly proportionate to the density or resistance of the atmospheric obstacle.

We know that if it were possible to produce an absolute vacuum between two separated terminals of opposite polarity, that an electric current would flow from one to the other, without involving any loss of energy, and consequently neither produces luminous or thermal effects.

The high intensity electrical currents as they flow into the earth in a circumscribed area, the centre of which does not correspond with an imaginary line drawn across the centre of the sun and the earth, might be imagined as capable of setting up the rotative action of the sphere, in some way similar to the tangential influence of an electric current on the drum armature of an electric motor (*vide* notes on wind currents). If the electrical energy of high intensity met the earth in equal intensity on both sides of a line imagined as drawn across her axis there could be no rotation, but we know, by the marvellous scheme of the Great Creator, that this is not the case.

The double planetary rotation might be explained in the same way.

The electrical, or magnetic, attractive influence of the sun, which we shall call gravity, on the earth is assisted by the suggested theory outlined.

It has been suggested that there are dynamo-electrical influences that are producing electrical energy to compensate for that absorbed on reflecting the rotation of the celestial planetary spheres, so that the loss of energy by rotation does not interfere with the completion of the cycle of conservation of energy. We know that the electric energy flows across a vacuous space without producing light or heat, but as soon as a gaseous intervening medium is introduced *heat* is produced, and with it a luminosity of varying colour and beauty, corresponding to the specific density of the intervening or interpolating gaseous medium. A gamut of colours is produced until the density corresponding to that of the atmosphere is reached, then the colour is daylight white. A

* That electrical energy flows through and not merely over the surface of the earth would require evidence of an electric flow through siliceous material of which the earth is composed; recently Hertz rays have been sent through large cliffs of rock. It is, however, well known that a large portion of this, the substrata of the earth, constitutes an aqueous reservoir—an excellent agent of electrical energy distribution.

simple but imperfect example of this is the arc light, the flash and the fork lightning. All the colours that one sees in experiments with vacuum tubes are reproduced in the earth's atmosphere. The celestial blue of the heavens, the violets, the amber-yellows, the strange and ghastly greenish tints associated with lunar effects, the colours of the fixed stars and those emitted from the solar corona, all can, it is believed, be produced by varying the density and gaseous character of the gaseous environment and intervention of two terminals of opposite polarity, and across which then flows a highly intense electrical current.*

That the earth, being a polarised conductor, is a distinctive magnet, and acts as such in its relations with the moon, is very likely, and as the instance of the earth's magnetic field in an electric ocean of low intensity can be compared to the magnetic field of an ordinary alternating dynamo, in an electric environment of low intensity there should be little difficulty in imagining that the rotative influence of the earth might set up incidental movements of rotation of the moon—movements, however, that may be influenced by the magnetic attraction of the great central solar electrical influence.

The peculiar ghastly luminosity of the moon can be easily produced by effecting an electrical discharge, through a highly tenuous gas, it can also be seen as a reflection of the almost invisible brush currents leaving one of the terminals of an electrical (plate) or other frictional machine.

There is no evidence to *disprove* that the moon is surrounded with a highly tenuous atmosphere corresponding to that by which the lunar brilliance can be imitated in a Crookes's or Geissler's tube.

It may be argued that the sun constantly transforming, as it is assumed to do, sufficient of the surrounding low intensity electricity of the electrical ocean into currents of high intensity, must show *non*-luminous evidence on her surface of the entrance into the great solar transformer and conductor of such compensating low intensity currents, because, inasmuch as the low intensity electrical currents flow into the sun, the sun's atmosphere at the points of absorption would be *non-luminous*. Unfortunately, the surface of the sun is radiating current of high intensity to innumerable points in the celestial electrical ocean, and the reflecting influence of the luminosity of the corona would illuminate some portion of the solar surface which is absorbing electrical energy of low intensity, in some degree commensurate with that which it is transforming and emitting at a high intensity; but even allowing for this incident reflection, one may point to the evidence of dark places on the sun's surface, which may be spots and blemishes on an otherwise grandly luminous face; but if this theory were accepted as correct, they would be spots sustaining a never-ceasing energy fecundity, and would constitute the most sublime *blemishes* of beauty ever conceived by man.†

The *periodicity* of the *sun spots*, and the fact that they influence the electrical (or magnetic) condition of the earth's atmosphere, are evidence that the writer's theory has some basis of fact.

The flashes of light that are thought by some to be tongues from a colossal combustion, are suggested to be merely evidences of variation in the density and extent of the solar atmosphere (photosphere and corona). The flashes, or ragged atmospheric edges, may be merely evidence of the projecting influence that the emission of the outflowing currents has upon the sun's atmosphere.

Whatever the constitution of the solar envelope illuminated by its resistance to the outward flow of electrical energy may be, the spectroscope should show its character, should it not? That is, if such an instrument can be relied upon for this purpose, it should show that the gas giving a specific colour tint, owing to its resistance to high intensity currents, should have a specific density, if it is assumed to be *hydrogen*, then red is the *tint* that should be shown when this gas intercepts the high tension rays flowing between two terminals of opposite polarity. We know that this is the tint, so here we have a coincidence of spectroscopic and electrical resistance effect of some value.

* A high potential or intense electrical discharge produced by a Holtz machine or a Ruhmkorff's coil shows that the luminosity of such discharge varies in colour in some definite ratio as to density; for instance, ordinary atmospheric air gives a white light with a blue image, the latter not unlike the celestial blue of a clear day. Nitrogen gas, which constitues some 75 per cent. of the atmosphere, gives a blue tint, whilst hydrogen gives a red one, and carbon dioxide a green tint. It is strange that this latter gas, that feeds plant life, should give the green tint of leaves. The incandescent vapours of gases giving characteristic Frauenhofer's dark lines, would, it is thought, give the same lines if rendered luminous by resistance to the passage of electrical energy of high intensity. In June, 1897, Sir William and Lady Huggins by artificial means had shown that calcium vapour when sufficiently attenuated radiates, under electrical stimulation, H and K lines alone, and this precisely coincided with the spectrum of the solar prominencies.

† Evidence.—Prof. Langley diagrammatically shows the correlation of sun spots with great magnetic variations in the earth.

Exact correspondence has been noticed between the sun spot influences in producing violent commotions in the sun and electric storms in the planet earth.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

At the meeting of the Institution of Electrical Engineers, held last Thursday, the 13th inst., at the Institution of Civil Engineers, a numerous company assembled to listen to the address of the new president, Mr. J. W. Swan. We noticed many faces which are not usually to be seen at the meetings. Chemists and physicists mustered strong in numbers to hear what an able chemist and electrician had to say on matters lying in the borderland between the sciences of chemistry and electricity. Nor were they disappointed, for the address suggested that electrical engineers have now a wide field for the disposal of plant in the domain of electro-chemical operations, which it is as much to the interests of the profession to work as the older business of lighting and the later outlet for electrical traction appliances.

The first serious business of the evening was the presentation by Mr. Latimer Clark to the Institution of a series of volumes containing important papers relating to the early history of submarine telegraphy and the work and labours of the late Mr. Jacob Brett. In offering these volumes to the members, Mr. Latimer Clark desired to draw attention to their contents and give some idea of the importance of certain memoirs included in the set. The remarks occupied a few minutes, which certain members present seemed to begrudge because the time was devoted to telegraphic rather than electric light interests. It was a great pity that any unseemly conduct should ever be permitted to mar the harmony of an offering to the library, but Mr. Alexander Siemens stepped into the breach, and at the right moment pointed out that to many of those present such things were of very great interest. He might have added that the meeting was one of electrical engineers, and not merely of electric lighting experts. Major Flood Page suggested that the presidential address was of first importance, but the majority evidently realised that there was ample time for both matters to be laid before the Institution.

Prof. Ayrton in a pithy speech characterised the best of Mance's methods as being Mance's method of filling the presidential chair, while the vote of thanks to the retiring President, Sir Henry Mance, was well seconded by Mr. A. A. Campbell Swinton in a few appropriate words, and the meeting settled down to listen to Mr. J. W. Swan, who took the chair.

Like most addresses, this may perhaps best be appreciated by a quiet study of the numerous points raised, when it is in print. The ground covered was so large, and the topics introduced so numerous, that the listener could merely follow the reader, without fully realising the truth and importance of much that was said.

As was anticipated, the first reference was to the meeting of 16 years ago, when, with Mr. W. H. Preece in the chair, one of the very first practical exhibitions of incandescent lamps was given, with the then Society of Telegraph Engineers and Electricians as audience, Mr. Swan as demonstrator, and Mr. Radcliffe Ward as engineer-in-charge of a farmyard engine and Gramme dynamo, the enthusiasm of the members was raised to a high pitch as the lamps lighted up. That occasion was the beginning of a movement that has always gone on, and has incidentally given an impulse to a larger and more general use of electricity.

The beneficial change from depressing darkness to brilliance almost rivaling that of day has, of course, partly been due to the arc light, but the unwonted brightness is not distantly connected with the insignificant looking bulbs that are such familiar objects now. The entire space between the early demonstration and the present day has been crowded with electrical invention and electrical work. Successful electric lighting and improvements in machines gave an impulse to a broadening of the applications of electricity. Telegraph engineering continued to grow up, while traction and power came more and more into prominence. Another growing industry is that of electro-chemistry, and this Mr. Swan regards as being of especial interest to young electrical engineers, as, in his opinion, aspirants would choose wisely in making a special study of the applications of electricity to chemical manufactures. A small portion of the field only has yet been cultivated, but this has already yielded good results. Copper, aluminium, gold, chlorine and soda are now obtained electro-chemically, while many other successful processes besides those employed in connection with the substances mentioned are at work on an electrical basis.

The importance of electrical processes is great and constantly increasing, either as an improvement upon known or existing machinery, or in the way of new methods being invented: in the one case, to do better what was already being done, and in the other, to achieve something previously unattempted. Considering the importance of the subject, Mr. Swan thought that the time at his disposal would not be ill spent in considering the rise and progress of electro-chemical industries.

The main portion of the address was now to follow. After briefly referring to the early work of Carlisle and Nicholson, Davy—"fortunate in almost everything, was supremely fortunate in his assistant"—and that assistant, Faraday—"the inheritor of Davy's methods and work"—Mr. Swan mentioned that in 1842 there were at work in Birmingham machines supplying current for the electro-deposition of silver and gold. At the time the "dynamo had not issued from that mint, which by the coinage of a word seems to create the thing signified." Passing on the various processes for the refining, extraction, and deposition of copper, zinc, nickel, gold, silver, aluminium, and production of soda and chlorine, the production of phosphorous, carborundum, and carbide of calcium, a bird's-eye survey of the whole field was taken, and much matter likely to stimulate thought was presented. Due acknowledgement was made—as might be expected from Mr. Swan—that electric lighting has largely contributed to the degree of success which has been reached in electro-chemical work. Many points were casually mentioned which serve to attract attention to original researches. Thus the president has found that current densities of from 1 to 1,000 amperes per square foot of cathode surface may be used in copper deposition, provided that the condition of the solution and proper circulation be noted; the regularity and smoothness of the deposit depending principally upon the absence of solid particles in the electrolyte.

The descriptive portion of the address necessarily partook to some extent of the nature of a catalogue of known processes; as an index it must be highly useful, notwithstanding all that has recently been written on cognate subjects. In fine, everyone must admit that in choosing electro-chemistry as the principal subject matter of his remarks, Mr. Swan chose wisely, and did good service to those who have placed him in the highest position within their gift.

THE N.C.S. LOW RESISTANCE MEASURER.

THE object of this apparatus, which is shown in general view and in diagrammatic form by figs. 1 and 2, is to supply a simple means of measuring very low resistances, which can hardly be determined by an ordinary bridge, owing to the difficulty of making the contacts, and other reasons. The method of working is to pass a current (which does not require to be known) through the resistance to be measured and a thick stretched wire on the instrument in series with it. The fall of potential over the unknown resistance is then balanced against the fall of potential over more or less of the thick stretched wire; the differential galvanometer mounted on the board being used for the purpose. The resistance to be measured when the balance is obtained is read direct by a pointer on a scale set at the back of the stretched wire. The length of the scale is one metre, and is

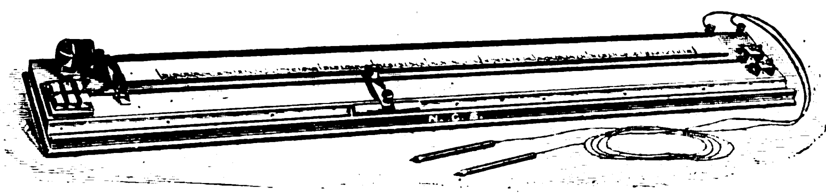


FIG. 1.

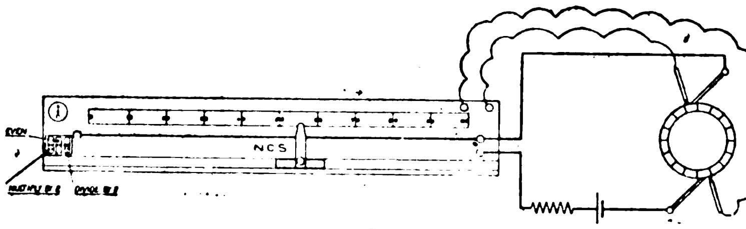

FIG. 2.

exactly equivalent to $\frac{1}{10}$th of an ohm; it is divided into a thousand parts, each of which is equal to $\frac{1}{10000}$th of an ohm. By shifting a plug the values may be multiplied or divided by 2, thus making the top read $\frac{1}{5}$th or $\frac{1}{20}$th of an ohm. (These plugs are in the galvanometer circuits; they are not in any way shunts on the main wire).

In using the instrument the terminals are joined in series with the resistance to be measured, and with a cell capable of giving, say, 10 amperes, a resistance, if necessary, being introduced to bring the current down to about 10 amperes.

The switch-key on the left, being depressed, closes the battery circuit. The sliding key is then slid along the wire, and manipulated as in the ordinary metre bridge, until balance is obtained on the galvanometer; the sliding key then points to the value of the resistance under test.

The whole length of the wire is ·1 ohm. The scale is numbered from 0 to 100, the readings being in thousandths of an ohm; each thousandth being again divided into 10. For example, if the read is (as in the figure) 56, the resistance is 56 thousandths of an ohm, or ·056 ohms. In the same way a read of 56·4 would be 56·4 thousandths, or ·0564 ohms; these are if the plug is in "equal." If the plug is in "multiply by 2," the resistance is $56{\cdot}4 \times 2 = 112{\cdot}8$ thousandths, or ·128 ohms. If in "divide by 2" it is $\frac{56{\cdot}4}{2} = 28{\cdot}2$ or ·0282 ohms.

It may be added that the resistance of connections does not affect the test in any way if a reasonably clean contact is made.

The whole instrument is certainly a very practical and serviceable one.

CORRESPONDENCE.

Practical Points in the Design of a Shunt Dynamo.

In your issue of 7th inst., No. 1,050, is first number of an article entitled "Some Practical Points on the Design of a Shunt Dynamo."

In the fundamental equation for finding the size of armature, having given the output, n is given as revolutions per *second.*

In the next equation, figures are substituted for letters, but the author then gives the revolutions per *minute*, viz., 320.

Will you kindly clear this point in one of your subsequent issues?

W. J. Axworthy.

In reply to Mr. Axworthy's letter, I regret that an error should have crept into my article. The first equation is of course wrong, as the 60 should have been omitted.

n = revolutions per second, and the second equation is multiplied by 60 for that reason.

V. Zingler.

On the Cause of Death by Electric Shock.

In the paper on this subject by Prof. Oliver and Dr. Bolam, which appears in the *British Medical Journal* of January 15th, the authors give tracings of blood pressure and respiration curves to show that death by electric shock is due to arrest of the heart's beat and not to respiratory failure. I, therefore, beg leave to draw your attention and that of your readers to the fact that this very matter was fully dealt with by me in a paper in the *British Medical Journal* of March 2nd, 1895. Anyone referring to that number will see that the experiments, the tracings, and the deductions drawn from them, all correspond exactly with those of the present paper, the only exception being that Prof. Oliver and Dr. Bolam used an alternating current, while I used a continuous. Although my paper has been overlooked by them, it is noteworthy that the authors refer to the existence of an opinion that death in these cases might be due to heart failure. That opinion was put forward in 1890 by Dr. Tatum, after experiments made by him, and it was supported and confirmed by the experiments reported in my paper of March, 1895, at a time when the profession generally was accepting the view of Prof. D'Arsonval that death in these cases was due to respiratory failure. It is gratifying to me to find that the experiments by Prof. Oliver and Dr. Bolam confirm so fully the results which I published in 1895, and show that alternating currents act in the same manner as continuous.

My paper was printed in the *British Medical Journal*, reproduced in the Electrical Review, embodied in a short paragraph in the second edition of my book on "Medical Electricity," and made the subject of a communication to the Physiological Society. Therefore no great amount of research is required to discover it.

Dynamo Sparking.

Re the letter dynamo sparking, I think that "W. H. B." is wrong in adopting any such device as he explains for the automatic shifting arrangement for the brush rocker on his dynamo which he is using to supply current for motors. If he uses a solenoid with a movable armature, which in turn moves the brush rocker, I am of opinion that the same sparking will ensue as formerly. If the dynamo be running at a light load, and a motor is switched into circuit, a large current will have to traverse the coils of the solenoid to move the rocker, and during that moment sparking will ensue.

Now sparking between the gauze brushes and commutator will roughen the strips, and so make collection bad, accompanied with sparking, which increases as time goes on; and in a short time it will not stop, owing to the increased roughened surface of strips. Now I think it would be better for "W. H. B." to adopt carbon tips to the end of the brushes. The carbon will offer increased surface to collection (which will tend to decrease the volts, but not more than a fraction per cent.), and so render collection easier, with less sparking, and is less detrimental to the strips, as it takes over the sparking, and does not produce the burning and scoring effect as takes place with gauze brushes alone.

The tip need not cover more than a strip, or, if this will not suit, it would be as well to substitute the present brushes by those of carbon only, which I am sure if properly set and adjusted there would not be the least trouble with them.

There might be signs of sparking, but it will not be detrimental to the machine.

Carbon brushes need no little skill in adjustment; and if they are not properly set, they will prove worse than those of gauze.

I am sure if "W. H. B." would substitute for his brushes those of carbon he would be greatly relieved from trouble and anxiety by having sparking reduced to a minimum, and so by working his machine under fairer conditions, as carbon brushes allow of a large variation of load without altering the lead.

Charles Whinsa Nicholl.

"Dynamo-Electric Machinery."

May I draw attention to an error in Prof. Silvanus P. Thompson's valuable work? On page 434 of the fifth edition, it is stated that Mr. H. F. Parshall's 150 k.w. street-car generator has a duplex armature winding. From the other data given, however, it is evidently a single-winding; for, applying the formula given in Hobart and Parshall's "Armature Windings" (a formula, by the way, in which $\frac{n\,C\,N}{10^8}$ is reduced to more convenient terms) we find that for a single winding

$$\text{volts} = 5 \times 6{\cdot}16 \times 2 \times 8{\cdot}7 = 536,$$

which is approximately the required amount, whereas with a duplex winding

$$\text{volts} = {\cdot}25 \times 6{\cdot}16 \times 2 \times 8{\cdot}7 = 268.$$

I notice that nearly all the plates in the book have the scale given, which greatly enhances their value. Had this been done in the case of Plate X. (illustrating the machine referred to) one could have got at the induction and current densities, which would have enabled one to make interesting comparisons with other machines.

W. Casson.

January 14th, 1898.

[Should not ·25 in the second example (it is so in the MS.) be 2·5, otherwise the working out is wrong.—Eds. Elec. Rev.]

Lampholders.

As the expiration of the Ediswan patents on lampholders is coming on, it occurs to me it will not be out of place to sound a note of warning to fire insurance companies, through the medium of your columns, and I shall therefore be glad if you will give this letter a corner in your valuable Journal. Already samples of what we may expect are being put on the market, and as I write, I have before me the letter of a Government official, who says ever since the patents for the Edison screw holders expired, their department have had the greatest difficulty in getting satisfactory holders of this type.

My business takes me all over the country, so that I see work of all sorts, and I can assure you I have seen hundreds of lamps installed, both as to workmanship and material, in such a manner as would make Mr. Heaphy's hair stand on end.

The invariable answer I receive when I venture to point out the danger is, "Oh! the fire office have passed it," and with the general public, who know nothing of the danger they run, this appears to me to be a guarantee, in their opinion, as good as a certificate from a consulting engineer superintending the work on their behalf.

Much has been written about jerry workmanship, but in my opinion jerry material is quite as much to be condemned, and the fire offices having set themselves up as "authorities" on the subject, should do the thing thoroughly, as at present their clients are in many instances resting in false security.

The fire offices would do the electrical profession a valuable service and reduce their risks if they collected together a number of specimens of electrical accessories of all classes and makes, and classify them, so that the uninitiated could go to the office of the company they are insured in and see what they should have put in their buildings, and what they should avoid.

Plenty of the public pay good prices for jerry work through ignorance, and the more the fire offices do to dissipate this the better for themselves and the better class manufacturers, who have to fight against it.

Let them start on lampholders; they will have a busy time shortly.

Walter Blenkarn.

January 18th, 1898.

THE ENGINEERS' STRIKE.

The chief anxiety of the A.S.E. this past week seems to have been that the *status quo ante bellum* should be secured. Juvenile copy-books once contained a line stating that "Time which has past will never return." There can be no return to the ante-strike period; the men cannot go on where they left off. The hours' question—that "popular" breeze to which the A.S.E. so gaily spread their summer sails, has died away into a very dead calm, only to be succeeded by the cyclone of management questions, and a veritable tornado of bottled up grievances on the points of restriction and loafing, which, though it may be marked by wreckage, will undoubtedly clear the air, and leave an open way for a different future. Now that the men are beaten, the greatest kindness that can be shown them is to see to it that future concessions have nothing of the element of weakness in them; no giving way to unreasonable demands for peace sake, and no bending before the ignorant demands of self-appointed agitators. Let Mr. Burns be followed in his cry for American methods, albeit he spoke better than he knew.

It was reported on Friday that the hours' demand had been unconditionally withdrawn. This was denied by Mr. Barnes, but it was not thought he was in a position to know. Telegrams came from Manchester and Glasgow to the effect and Mr. Barnes gave somewhat indirect denials. He was busy at his trade, however—getting out a fresh manifesto. What a charm there is in these huge words for the agitator! Half the dispute seems to have been so much mouthing of long Latinised words. Manifesto, conference, delegate, come in shoals, and help to impress the simple workman.

Anyhow, Mr. Ferguson, the Glasgow local organising delegate, made a statement as to the hours' demand being withdrawn, and he confirmed the statement publicly to a reporter. The Employers' Federation, on the other hand, do not accept a simple withdrawal of the 48 hours' demand as closing the question. They do not intend to start any men who will not toe the mark on the basis of the amended proposals of the Federation, and there can be little doubt but that the men who accept will soon find the benefit of honest effort in increased pay, and will not countenance a return to skulking methods. The active of the strikers have been probably almost to a man youngsters who have not any remembrance of the times before restriction set in. They have been brought up on restriction, and possibly before long will be astounded at their own folly in listening for a moment to the commands of such leaders as have compelled them to such exhibitions of ignorance.

The Fairfield lock-out was a great blow to the strike leaders, who did not, as formerly, at once withdraw the 75 per cent. not locked out. This was generally considered a sure sign of weakness, not to be glossed over by all the financial juggling with figures as to funds available. Mr. Barnes keeps harping on his willingness to arbitrate, on the eight hours' question, and indignantly denies the charges as to connivance at restriction. Now this is really too bad, when all the country knows that restriction has been everywhere; the shop delegate has been pushing the accursed thing in every union shop; foremen have been interfered with in their duty, and for months chance labourers and apprentices have been beating the old hands by large percentages.

Mr. Barnes is fighting in the last ditch, and demanding to exercise the right of interference. Had Mr. Barnes won the day, he would have demanded eight hours, would have restricted output still further, and most probably he would have insisted upon there being a recognised trade union official in every shop—paid by the employer, of course—to interfere at every turn. Mr. Barnes' one and only mistake in the whole quarrel has been of the sort that expects to pour a quart of ale out of a pint pot. Of course he would have failed, but he would have smashed the pot. As it is, the pot has smashed him, and he is simply making himself ridiculous by his present attitude. We may admire a man who fights because of his pluck; we may pity him for his ignorance in fighting for a bad cause, or despise him if he does not fight fair, but when a man becomes the object of ridicule he is lost.

Sir E. J. Reed writes a capital letter to the *Times*. He recalls how the late Sir Joseph Whitworth, at one of the Paris exhibitions, foretold the present conditions when pointing out how foreigners, by means of Sir Joseph's own inventions, were rendering competition keen. The danger, said he, will lie with the men, who will be a long time learning that they will have to compete with cheaper men.

Sir Edward instances numerous articles he has seen which have been made abroad which he has come across in recent visits through English workshops. Without any special sympathy with employers, he sees that trades unionism, in striking at them, really strikes at the poor working man, who is the dupe of his leaders. He sees how the workmen get as much as a hundred times in wages what the employer gains as profit. He sees thousands starving as a result of a war, of which the first shot was fired by the men in London, who were working for shorter hours than millions of their fellow countrymen, women and children are working for much barer subsistence. The naked hideousness of the struggle appeals to him as to any other open-eyed man. Yet he says the men's leaders see nothing but a vulgar contest with employers and capital, as though, we may suppose, capital were a source of evil. He has not much sympathy with employers. They should have combined long ago, and kept the unions sane and reasonable and considerate. Sir Edward, in fact, repeats what we have urged, that it is the weakness in making apparently expedient concessions has caused the frog to blow himself out. The unions have, in fact, gone altogether beyond their legitimate sphere of wholesome influence, and this has ruined them by enticing them into their domineering and arbitrary attitudes. Sir Edward concludes a thoroughly sound letter with these words:—

"I have no scheme of settlement to suggest. The unhappy employers, while facing the fire of competition, are, it seems to me, attacked from behind by the representatives of the very people for whom they are making the fight. For, if I may, I will repeat that we have to-day to fight foreign competition in many countries, over many manufactures, and in many forms, and the people whom we have first to protect are the working classes of this country. The men who are in the forefront of this battle, and who must remain there, are the employers; but they are few, and for them, in themselves, we need not be greatly solicitous. It is by them and through them, however, that the interests of the working people of this country have to be maintained, and these ought to be maintained at all costs. Is it too late to ask, or is it too much to ask, that a contest which has become as ruinous as it is unnatural may be forthwith ended and a new chance be given to our own people and our own country in the international struggle?"

Probably for this letter Sir Edward Reed will be fiercely attacked when he next contests a seat in Parliament, by the very men whose real interests he has at heart. Such is the working man of to-day.

In the meantime the Manchester shops have opened their doors to non-unionists who were prepared to accept work under conference rules, and it is also understood that unionists may be employed who have definitely left the union. Very few of the latter had done so up to Saturday last, and of course they could not be taken on as unionists while their unions still maintained the 48 hours' demand.

A trades unionist writing to a contemporary denounces the so-called new unionism, which he calls upon all solid unionists to exterminate. He denounces also so much federation of unions. But for this he considers that the London struggle would not have extended to the country. It was the federation of trades union that compelled the Employers' Federation. He calls for home rule. Let every district stand alone, and so avoid the national calamity of wide-spread strikes and equally of widespread lock-outs. But it is 25 years since the last great strike. There have been numerous smaller ones in between, but the accumulation of wrong doing and error and weakness which have brought on the present struggle has been of 25 years' growth.

Before another such period has gone by we may hope that an advanced intelligence and a better knowledge of the facts of foreign competition will prevent so suicidal a thing again taking place. That some kind of benefit is desirable is the opinion of everyone. In a letter to the *Times* Mr. Maudslay suggests what seems a likely scheme. By it every workman would have control of his own funds, and if he elected to use them for purposes of a strike he would be at liberty to withdraw them for the purpose, subject simply to the safeguard that he could not draw them by proxy, but must himself draw the money before handing it over to the agitator of strikes.

Mr. Maudslay considers that the handling of the cash in solid sovereigns would usually be sufficient to induce at least a very careful consideration of the case before handing the coin to the strike fund. At present, the workman has no control over his funds, and the actuarial basis of the A.S.E. is considered by men versed in such matters to be far from sound, as, indeed, has been shown more than once by a reduction of promised benefits. The Society, in fact, promises more than it can carry out. How it will now get along is very doubtful, and the present would be a very good time to start a men's benefit fund on some such lines as Mr. Maudslay indicates; a fund from which each member could withdraw if he chose to do so, and officered by men amenable to strict commercial law, and under the guidance of properly appointed trustees. If apart from the benefit fund the men desired to keep up a strike fund they would be at liberty so to do, but it ought to be made illegal to employ any benefit fund for strike purposes, and the law should forbid the carrying on by one executive of the two functions of benefit and strikes or disputes, and should forbid the transfer from one fund to the other of money in any shape or form, except only as the man personally withdrew the money in coin, and carried it away himself. And even this we would make a matter of some days' notice, the man to be first shown the money he is to draw in gold, and then given it so many "thinking" days afterwards, during which he would have time to consider matters before making a leap in the dark, and he could consult those at home, who have the brunt to bear when dealings commence with the pawnshop. Mr. Maudslay's letter has roused the ire of Mr. Barnes, who throws all the blame on the workmen, of whom he is simply the innocent and harmless mouthpiece. This is good.

Since writing the foregoing it is publicly announced that the eight hours' demand has been withdrawn. It was so reported last week, and the report described as a fairy tale by Mr. Barnes, and as a canard by Mr. Brown. What Mr. Burns said we know not. It is reported, however, that "for the suffering they have undergone, the men demand compensation;" but from whom is not clear. They have suffered voluntarily for 28 weeks, refused good wages, and plunged the trade of the country into a pit, and ask for compensation. Many trades union leaders admit that the sole result of the half-year's struggle has been to raise a rival power, which will make it impossible in future to dictate terms to individual employers. There is one other result—the ruin of the A.S.E., morally and financially. Union folly was never so clearly manifest as now, when the nominal *casus belli* has been formally withdrawn, war is declared still to be the order of the day, because the employers insist on being victors in respect of the true *casus belli*—the question of management. Sanguine local leaders are saying that there is no reason why the men should not at once resume their places, as though it were but the second week of last July. But it is the third week of the following January, and it is certain that the new men are not going to be sacked to suit the strikers' convenience. If the new men are discharged, we should hope the employers who do so, or even permit them to be worried away, will receive due retribution. On this point there are bound to be troubles. The bellicose unionists will do their worst to render the lives of the new men miserable, and this must not be. The employers are bound to see to it that peace shall prevail, and that disturbers of it get the run out quickly. In the meantime large numbers of men are leaving the union, and going back to work. As we predicted early in the strike, the old hands are inclined to stick to the union for the sake of their old age benefits, and the young men, who have been the cause of the war in a large measure owing to their recklessness and a desire for a cheap summer holiday, are throwing the union over rather than face future levies. We condemned the strike as a cowardly robbery by the young men of the old men's funds, and we have proved correct. Some of the daily papers still plunge wildly in the dark as to facts. Among these the *Daily News* calls for a compromise.

What compromise can be possible that will be of the slightest value? There is but one issue, and that is summed up in the one word *output*. Are the men's "friends" still asking that there shall be restriction of output? It looks like it, or else it looks like ignorance. The whole British working man is permeated with the idea of restriction. A bricklayer does not set as many bricks in a week as he could easily set in a day without overworking himself or doing bad work. And this evil, which is eating out the heart of the country, is to be compromised. Away with such nonsense. Let the men get back to work, and show by decent honesty that we can beat any other nation if we choose to do so. Let them make up their minds to earn more money and to see that they get it.

Compulsory arbitration again is not likely to be acceptable. Arbitration so commonly ends in the granting of a part of any demand that the men would be making constant big demands in order to get a part by arbitration. This would land us in similar demands by the employers, so as to get something back again. There would be no finality. There is room for some such body as the Board of Arbitration and Conciliation of the Manufactured Iron and Steel Trades of North of England. This seems to have worked well, but has been fortunate in its men, from both sides. But compulsory arbitration or Parliamentary interference will not do. We are inclined to think that the Employers' Federation will steady matters for a time, and hope to see some suitable arrangement arrived at that will prevent future wars. The great lesson to be relearned is, however, that machinery is not of necessity an ouster of labour. If the men only learn this the end of nine-tenths of the recent troubles will have arrived. The other great cause of trouble is the question of demarcation. Nothing is to be done for this beyond the most drastic commandeering. The idea of demarcation has become absurd through being carried to absurd length. Anyone making trouble on this score ought to be severely dealt with.

ELECTRIC POWER DISTRIBUTION.

A few days ago the secretary (Mr. Lowe) of the Midland Electric Corporation for Power Distribution, Limited, approached Sir B. Hingley, Bart., chairman of the South Staffordshire Iron Trade, and Mr. J. B. Cochrane, chairman of the South Staffordshire Coal Trade, with the object of enlisting their sympathy, and the sympathy of manufacturers generally, in the scheme of electric power distribution which the Corporation have embraced in their provisional order. As a result a meeting of manufacturers was held in Birmingham yesterday (Thursday). In his circular Mr. Lowe states:—

"The Midland Corporation is prepared to enter into agreements to supply electrical energy for power or manufacturing purposes at as low a price as 1d. per Board of Trade unit, and for lighting at the rate of 6d. per unit for the first hour's use per day and 3d. per unit for each subsequent hour's use daily. The Midland Corporation is also prepared to lay a comprehensive system of mains throughout the district, and will supply motors for hire, so that manufacturers can secure the advantages of electrical power at the minimum of capital outlay."

Here follows a comparative statement of the prices charged in 15 towns—Blackburn, Bradford, Bristol, Cardiff, Coventry, Edinburgh, Glasgow, Halifax, Leicester, Liverpool, Nottingham, Stafford, Sunderland, Walsall, Wolverhampton—in which the local authorities own and work the electric lighting orders, and which have been selected as being favourably situated for coal supply. The secretary claims that this statement demonstrates the impossibility, on account of the limited area to be supplied, of any individual local authority (of approximately similar rateable value to the towns in the area applied for) being able to sell electrical energy at anything like the figures at which the Midland Corporation will undertake to supply it.

The secretary then goes on to state that in order to carry out its objects, the Midland Corporation has served statutory notices upon, and deposited plans, with all the 18 local authorities in their proposed area of supply. The secretary adds:—

"Of these authorities, the Councils of Dudley, Walsall, and Wolverhampton already possess electric lighting orders, under which they now have the sole right to supply energy for power purposes, while the Councils of West Bromwich, Oldbury, and Smethwick are applying for similar orders in the present session of Parliament. The Midland Corporation has had no wish whatever to interfere with the lighting of these boroughs or urban districts, except with the consent of the local authority, but it submits that it is hardly within the sphere of operations which should be under municipal management to start this business of power supply; in other words, it contends that risks which are inevitable in a new enterprise of this kind, and which a company may be justified in incurring are unsuitable for a municipal authority to embark upon, having regard to the fact that they must borrow money on the ratepayers' account to enable them to do so.

"In view of the opposition to the scheme from certain of the local authorities (without whose consent it is doubtful if the provisional order can be obtained), the promoters of the order feel that the time has come when the iron and coal masters, and the manufacturers generally in the district, should be made thoroughly acquainted with the scheme, so that they may bring their influence to bear in support of the application of the Midland Corporation and assist in the introduction of electrical energy as a motive power into the district."

BUSINESS NOTICES, &c.

Board of Trade Returns.—The foreign trade returns for the past year now completed, says the *Daily News*, show less satisfactory results than were at one time anticipated. For the first six months of the year the imports showed a gain of over 4 per cent., while there was a moderate reduction of 1½ per cent. in the exports. Owing chiefly to the effects of the increased American tariff, and of the strike in the engineering trade, the decrease in the exports for the year has reached £5,795,000, or 2½ per cent., while the increase in the imports is £9,429,000, or 2 per cent. The chief proportionate reduction in exports is under the head of machinery and mill work. Steam engines show a decrease of £124,000, and other descriptions £298,000. Among metals there were increases of £75,000 in copper, £53,000 in telegraph wires, and £33,000 in iron.

Business Announcement.—Mr. A. Alan Jenkins has joined Messrs. Lloyd & Read as a partner. The firm, now known as Lloyd, Read & Jenkins, has removed from 63, Broad Street, to more commodious premises at All Saints Chambers, High Street, Bristol. The lighting of the Bristol Commercial Rooms, and the new sanitary offices, Queen Square, has just been carried out by this firm.

Catalogues, &c.—Messrs. Bergtheil & Young, of 12, Camomile Street, E.C., who are the sole agents for the United Kingdom for the Bullock Electric Manufacturing Company, of Cincinnati, have sent us lists of that company's manufactures. The lists illustrate and particularise direct current dynamos of various types for belt and direct connection, and some detailed notes are given of the principal features of their method of winding armatures. There are also several photographs of printing presses of different makes, with their direct connected slow speed motors, and views are shown of motors connected to lathes, drills, and other machine tools.

Messrs. J. D. F. Andrews & Co., of Fulham, have issued an 1898 edition of their catalogue of their systems of concentric, double, and conduit wiring. Comparative estimates are given, showing the cost per 16-C.P. lamp wired on this system and on the wood-casing method. Joints, sockets, nipples, switches, fuse and switchboards, lampholders, pendants, and various other accessories for use with the system are described and priced.

A folding list with stiff green covers has been sent out by Messrs. Veritys Limited, describing the "Standard" main switchboards. There are several different types shown:—(*a*) for plain dynamo boards; (*b*) for extended dynamo boards; (*c*) for multiple dynamo boards; (*d*) for plain accumulator boards; (*e*) for extended ditto. There are also types of main distributing boards. The list is very nicely printed and is conveniently arranged.

Messrs. Cutting Bros., of Derby, are sending out a wall card, giving a useful discount table from 2½ to 50 per cent.

The Edison & Swan United Company's Section VI. catalogue, dealing with fancy fittings, electroliers, brackets, &c., has been issued. It is dated January, 1898, so is right up to date. The list, which, like all Ediswan catalogues, is nicely laid out and fully illustrated, shows many designs of plain and fancy brackets, some of which are very artistic. This remark also applies to a variety of fancy table and floor standards, ceiling fittings, pendants and electroliers. Special bronze and Doulton ware figures and elaborate candelabra are also illustrated.

Canada as a Mica Producing Country.—Since the application of mica for electrical purposes, the production during recent years has assumed considerable importance, and on account of its abundant occurrence in excellent quality in Canada the attention of capitalists has been attracted to mica properties in the dominion. Canada has long been known to be rich in economic mica deposits. More than 30 years ago, Sir William Logan ("Geology of Canada," 1863, pp. 494-5 and 795) referred to the deposits of "Muscovite" or "white" mica, then known to exist on Yeo's Island, Cape Tourmente, and other sections of Quebec. Mention is also made of the phlogopites or "amber" mica at Grenville, Quebec, and in North and South Burgess, Ontario. "In all of which," says Sir William, "the mica is obtained in large sheets, which being transparent and free from flaws, are wrought and employed for the same purposes as the 'Muscovite' or potash varieties." An early producer was the Sydenham property in the Kingston district, and an important deposit of "Muscovite," particularly referred to by Dr. Selwyn, director of the Geological Survey of Canada, in the Report of the Royal Commission on the mineral resources of Ontario, has been opened at Villeneuve, in Ottawa County, while at Templeton, about 16 miles from the city of Ottawa, several extensive deposits of first-class "amber" mica, notably on the Wallingford property, have been worked. Dr. Selwyn's high opinion of the Villeneuve "Muscovite" mica is fully confirmed by another well-known Canadian expert, namely, Prof. F. Cirkel, who has also reported in high terms on the Wallingford and the Lake Gerard properties. Referring to the output of the last named, it is recorded to have been as high as 122 tons in a month.

Concert.—On Friday last a concert was given by the People's Palace Electrical Class.

Contradiction.—We are authorised to contradict that portion of the *Westminster Gazette's* statement, published in our last issue, to the effect that Messrs. Easton, Anderson & Goolden, had entered into an arrangement with Messrs. Schuckert & Co. for manufacturing electrical plant under their patents, the rumour being without foundation.

Dissolution of Partnership.—Mr. W. H. Slater, of Slater and Spurgin, electrical engineers, of Holloway Road, wishes to notify that Mr. Malcolm A. Spurgin having left the firm, he will carry on the business in his own name.

Electric Pumping.—*Daily Tenders and Contracts* says that the Harrogate Corporation has decided to work the pumps at the Sewage Farm, Ripon Road, by an electric motor in place of a gas engine.

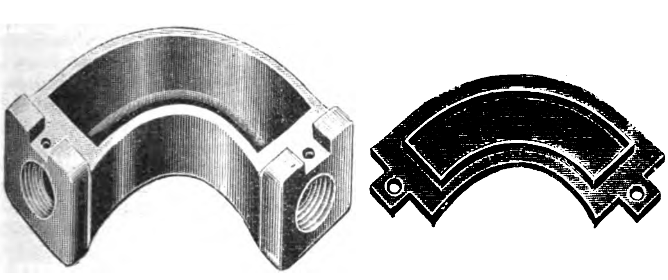
Fire.—On 13th inst. a fire broke out at Harrison's Electrical Engineering Works, Soho Street, Pemberton.

First Meetings.—The first meetings of creditors and contributors in the Ward Electrical Car Company will be held on January 26th at 11 and 11.30 a.m., at 33, Carey Street, W.C.

Gas.—A serious gas explosion occurred at the works of the English Gas Company, at Schoeneberg, Germany, on 13th inst., three persons being killed, and three severely injured.

German Enterprise in South America.—An indication of the enterprise of German firms is afforded by the formation in Berlin of the German Transmarine Electricity Company (Deutsch-Ueberseeische Elektricitats-Gesellschaft), under the auspices of the well-known Allgemiene Elektricitats Gesellschaft, the Deutsche Bank, and several other German banks. Mr. Emil Rathenau, of the Allgemeine Company, is one of the directors of the company, which has been constituted with a capital of 10,000,000 marks. The company propose to establish electrical installations of all kinds in America, and as a commencement, a lighting and power station is to be built at Buenos Ayres.

Interior Wiring.—Messrs. Newsome, Pinching & Co., of 1, Crutched Friars, E.C., are the sole agents for Russell's patent accessible bend, which we illustrate below, the drawings being self-explanatory. The bend is the device of Mr. C. N. Russell, the



electrical engineer to the Shoreditch Vestry, and it is largely used in connection with the lighting installation at the New British Gallery of Art, Grosvenor Road. The firm also makes a speciality of circular switch cases, circular four-way boxes, and Russell's straight box, all the fittings being screwed for iron gas barrel.

Kaye v. Croydon Tramways Company.—Mr. Justice Kekewich heard this case in the Chancery Division last week, it being a claim by a shareholder in the Croydon Tramways Company for an injunction to restrain the company from carrying into effect an agreement for the sale of the undertaking to the British Electric Traction Company. The injunction was granted. It appears that the principal ground for the application for the injunction was the provision under the said agreement for the payment of various sums, amounting in all to £3,250, to the directors and officers of the company for compensation for loss of their positions by the purchase.

Lazare Weiller.—Mr. Fernand Espir, the English representative of the well-known Compagnie des Etablissements Lazare Weiller, sends us a nicely framed view of the very extensive works of that company at Havre, also showing the dwellings of the workmen on the outskirts of the works.

Liquidation Notices.—A meeting of the Electrical Installation Company will be held at 135, Victoria Street, Westminster, on Friday, February 18th, at 2.30 o'clock, to receive an account of the winding up from Mr. O'Brien, the liquidator.

A meeting of the River Plate Electricity Company will be held at 78, Coleman Street, on February 23rd, for a similar purpose. Liquidators—Messrs. J. H. Duncan & T. S. Hamilton.

A meeting of the Acme and Immisch Electric Works will be held at 2, Clement's Inn, Strand, on February 4th, at 3 o'clock, to hear an account of the winding up from the liquidator.

Photographic Exhibition.—The Royal Photographic Society is organising an International Exhibition of Photographic Apparatus and Photographs, which will open at the Crystal Palace on April 27th. There will be extensive loan collections, illustrating the enormous scientific and commercial applications of photography, photographs in colours, photographs by means of the X rays, and kindred exhibits.

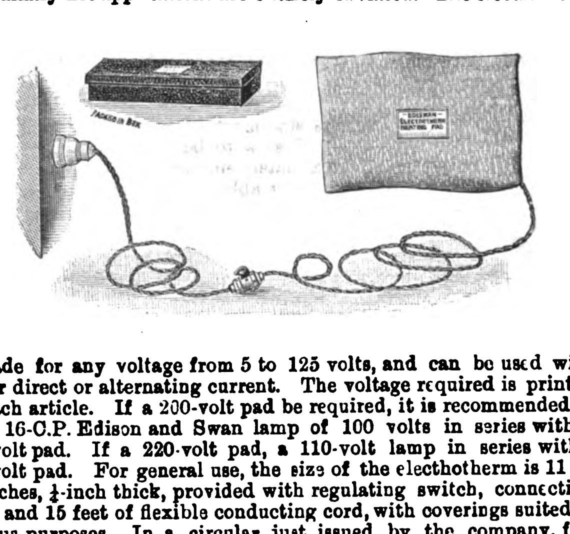
Soldering Paste.—Messrs. Beanland, Perkin & Co., of Leeds, are placing on the market Burnley's rozinal soldering paste, which is claimed to contain no acid or other substance injurious to wires or insulation. It is used for soldering armature connections, commutator bars, or field connections. By using this paste, it is claimed that wires can be soldered in half the usual time, and the finest wires can be united without oxidisation or injury to insulation.

South African Electrical Notes.—The *British and South African Export Gazette* has the following electrical items in its January issue:—Orders for various types of transformers and motors have been placed with European firms by the Rand Central Electric Works, Brakpan, Transvaal. The new electrical installation supplied to the Transvaal Gold Mining Estates was furnished by Messrs. Siemens & Halske. It is on the three-phase system and of a pressure of 3,000 volts. Part of the material for an overhead system of electrical traction for the Sheba mine has been shipped. The East London Town Council is, we understand, meditating an electric light installation. In the event of the electrical machinery for the Sheba mine not being recovered from the wreck of the *Clan Gordon*, duplicate orders for machinery will have to be placed. The second electric motor to complete the projected equipment of the Piggs Peak gold mine has been shipped. Two electric 25-H.P. locomotives have, we understand, been supplied to the Transvaal Gold Mining Estates.

South v. Lowenfeld.—This was an action heard at Westminster to recover £18 odd from the lessee of the Prince of Wales' Theatre, Coventry Street, W., balance of account for electrical work at the theatre. It was admitted that the orders were received through one Woods, the theatre electrical engineer, who was at one time also in the employ of plaintiff. On the other hand, plaintiff said that when he saw defendant at the theatre after the work was done, he said nothing about Woods not having authority to give the orders. The defence was that Woods had no authority to give plaintiff orders. Judgment was given for the defendant.

South v. Nathan & Summers.—On Thursday last week in the Westminster County Court, the case of South *v.* Nathan and Summers came before his Honour Judge Lumley Smith, Q.C. The plaintiff, Harry South, an electrical engineer, of Garrick Street, sought to obtain payment for making an electrical outfit for a lady, "The Wonderful Lamp." The defendants, music hall agents, employed Mr. South to fit a dress for Miss Hewitt, who was performing at the Palace Theatre in 1894 with electric bells, and her head-dress consisted of coloured electric lights. A battery was included in the apparatus. The account also contained an item for repairs. The defence was that Miss Florence Hewitt was the person liable. Judgment was given for the plaintiff for the amount claimed, with costs.

The Electrotherm.—The Edison and Swan United Electric Light Company is introducing the electrotherm, a patent heating apparatus, which has on several occasions been briefly referred to in our columns. We now illustrate the pad, which is composed of wires insulated and protected by asbestos, woven into a light and flexible sheet or pad, which, when attached to the ordinary incandescent lamp socket, offers sufficient resistance to the current to produce a constant and uniform degree of heat. The value and efficiency of the electrotherm are appreciated in cases of rheumatism, neuralgia, pneumonia, and other complaints, wherever the application of artificial heat is desired. By its use the risk and discomfort of frequent changes of temperature incident to the renewal of ordinary hot applications are entirely obviated. The electrotherm



is made for any voltage from 5 to 125 volts, and can be used with either direct or alternating current. The voltage required is printed on each article. If a 200-volt pad be required, it is recommended to use a 16-C.P. Edison and Swan lamp of 100 volts in series with a 100-volt pad. If a 220-volt pad, a 110-volt lamp in series with a 110-volt pad. For general use, the size of the electhotherm is 11 × 15 inches, ½-inch thick, provided with regulating switch, connecting plug, and 15 feet of flexible conducting cord, with coverings suited to various purposes. In a circular just issued by the company, full directions are given for use.

Utilisation of Water Power in Spain.—A proposal to put down plant to utilise water power in the Iguna Valley, in Santander province, in the generation of electrical energy, is at present under consideration. It is stated that 1,000 H.P. is available.

ELECTRIC LIGHTING NOTES.

Aberdeen.—The committee has agreed to consult Prof. Kennedy with regard to the proposals contained in the report by Mr. Blackman and Mr. Smith *re* proposed extensions before proceeding further in the matter.

Acton.—Mr. James de Lara Cohen does not propose to proceed further at present with his application to the Board of Trade for a provisional order giving power to light his estate at Friar's Place by electricity.

Alfreton.—An electric supply company has written to the District Council asking for consent to its proposal to supply the town with the electric light. The letter will lie on the table for six months.

Asylum Lighting.—The directors of the West Green Asylum, have, according to a Dundee paper, given a contract to the E.P.S. Company for maintaining the storage batteries at West Green and Gray House. The electrical plant at the asylum is now so far completed as to enable a 24 hours supply to be kept up.

Ayr.—The Burgh electrical engineer reports that for the month of December, through the heavy load of Christmas and New Year week, all demands for current were met. The machinery was overloaded but there was no trouble. The Commissioners will borrow—subject to the approval of the Secretary of State for Scotland—£2,000 for the purpose of wiring houses for the electric light on terms "similar to those of the London Electric Supply Corporation."

Balerno.—This Scottish village is now lighted by means of five arc lamps in the main roads. The Parish Council gave the contract to Messrs. Lowdon Bros., of Dundee, and current is taken from the Balerno Bank paper mills.

Bethnal Green.—The new infirmary is to be electrically lighted. At a recent meeting of the board it was stated that the architect's report on gas and electric lighting showed an expected saving of about £240 per annum by using electricity. Inquiries are also to be made as to whether the laundry machines shall be driven electrically.

Bexhill.—A Local Government Board inquiry was held on 12th inst. into the application of the District Council for a loan of £20,000 for electric lighting. The scheme was explained at considerable length. The plant would provide for 5,500 8-C.P. lamps for private use, as well as current for public lighting. There was some opposition.

Boston.—The Council has unanimously passed a resolution in favour of electricity. A scheme before the meeting was estimated at £20,000. The yearly expenditure was given at £800, as compared with £956 now paid for gas.

Bromley (Kent).—A correspondent says that considerable dissatisfaction exists amongst the members of the Bromley Urban District Council as to the transfer of the provisional order for lighting the town with electricity. It appears that the Council entered into a provisional agreement with a company called the Bromley Electric Lighting Power Company, and undertook to hand over the powers obtained under their provisional order for a specific sum of money, but as some doubt existed in the minds of the councillors as to who were the directors of the company, the Council have communicated with the Board of Trade, and the reply has been received that the present directors of the Bromley (Kent) Electric Light and Power Company, Limited, are Messrs. Medhurst and Taylor, both of High Street, Bromley, and Mr. Gripper, an electrician, of Twickenham, who have expressed their willingness to take £5,400 worth of capital, and other capital will be offered to the residents of Bromley as soon as shares are issued.

Burton-on-Trent.—At the last Council meeting the question of the recent failure of the electric light was discussed. It was shown that it was due to the breaking down of the India-rubber insulation.

Calcutta.—An Indian exchange says that very little has been done yet in regard to commencing work on the electric supply for Calcutta, which a local firm is to carry out on behalf of a syndicate. A committee has been appointed to settle matters in regard to overhead lines, and until this question has been gone into, progress will be purposely retarded, as much depends upon the acceptance of the company's proposals for the laying of mains in the several streets.

Chelsea.—The standing orders have been found to be complied with in the case of the Chelsea Electricity Supply Bill, which came before the examiners this week.

Colwyn Bay.—The Surveyor (Mr. W. Jones) has produced plans showing the two routes for the line of cables for electric lighting of the Promenade. The cable is to be laid along Lawson Road to the Parade.

Crieff.—A letter from Mr. R. Frederick Yorke was read at the last meeting of the Town Council, in which that gentleman puts forward a scheme for utilising water power for electric lighting, which he recommends instead of the steam scheme already under the Council's consideration.

Cromer.—The *Eastern Daily Press* says that the Highways Committee has received a letter from Mr. Gibbons, (?) Town Hall, Bradford, asking if the Council had any intention of transferring their provisional order for electric lighting to a company, and stating that if such was the case he would be able to submit an offer. The Council will consider a *boná fide* proposal.

Croydon.—Prof. Kennedy has been appointed consulting engineer to the Croydon Corporation from March 25th next at a salary of £100 per annum, with commission on certain work. Mr. Minshall, the present engineer-in-charge, has been appointed electrical engineer as from March 25th next, at a salary of £250 per annum, rising on September 29th to £300 per annum.

Enfield.—The General Purposes Committee is inclined to oppose the granting of electric lighting powers to the gas company, but has asked for the company's observations first.

Glossop.—A sub-committee of the Town Council is to see the manager of the Municipal Electric Supply Company *re* the electric lighting proposals put forward by that company. The question of putting down a municipal plant is not being lost sight of.

Gourock.—The Burgh Commissioners will oppose the application made by the North British Electricity Company for a provisional order.

Greenock.—The Electricity Supply Company, which proposed to apply to the Board of Trade for a provisional order to supply electricity in Greenock, does not intend to proceed with the application at present.

Hereford.—The County Surveyor has been looking into the question of lighting the Assembly Rooms by electricity, and has prepared estimates of the cost of plant, &c., but as a provisional order is now being applied for, nothing will be done in the meantime.

Hull.—A proposal to instruct the Works Committee to consider the advisability of lighting the Workhouse premises by electricity throughout came before the Board of Guardians, but there was opposition, and the proposal was negatived by a large majority, as the Committee "already had sufficient to do."

The tradespeople are asking for a reduction in electricity charges.

Ipswich.—A London electrical firm has approached some members of the Lighting Committee with a view to securing a transference to them of the Council's provisional order.

Ipswich (Queensland).—The Australian *Building, Engineering, and Mining Journal* recently gave the following list of the tenders submitted to the municipality for the supply of electric lighting plant and machinery, &c. Notice of the invitation of tenders appeared in the Review:—

		£
Section A.—	Crompton & Co.	1,020
	Siemens Bros. & Co., Ltd.	1,075
	Babcock & Wilcox, Ltd.	1,650
Section B.—	Crompton & Co.	856
	Siemens Bros. & Co., Ltd.	971
	Babcock & Wilcox, Ltd.	1,050
Section C.—	Siemens Bros. & Co., Ltd.	8,159
	Brush Electrical Engineering Co., Ltd.	8,200
	Babcock & Wilcox, Ltd.	8,550
Section D.—	Babcock & Wilcox, Ltd.	875
	Electric Construction Co.	417
	Siemens Bros. & Co., Ltd.	518
Section E.—	Siemens Bros. & Co., Ltd.	6,894
	Noyes Bros., Agents for the Callender Co.	7,316
	Brisbane Electric Supply Co.	10,068
Section F.—	Siemens Bros. & Co., Ltd.	725
	Crompton & Co.	760
	Nalder	785

Mr. Hesketh, the Government electrical engineer, who advised regarding the contracts, made the following notes: *Section A.*—The boiler I would prefer to have accepted would be the Babcock and Wilcox water-tube, but as the price seems too high I think the compound Cornish made by Messrs. Evans, Anderson and Phelan should be accepted. *Section B.*—If the Cornish boilers are obtained the steam pipes should also be ordered from them to save trouble. *Section C.*—Messrs. Siemens Bros.' combination I consider the best. *Section D.*—It is advisable to place the order for the switchboard with the successful tenderers for Section C. if the price is not prohibitive. I therefore recommend Messrs. Siemens' tender for acceptance. *Section E.*—I have personally great faith in the B. E. S. Co. cable, manufactured by the British Insulated Wire Co., and from personal experience can testify to its excellence. I have no reason, however, to doubt the excellence of the cable manufactured by the other two tenderers, and their prices are considerably lower. *Section F.*—The transformers quoted are all good, and in the final selection it will be on details that the decision must rest.

Jersey.—The *Times* says that the St. Helen's (Jersey) Parish Assembly on Tuesday adopted, practically unanimously, a petition to the States of the island in favour of a Bill empowering the municipality to borrow £30,000 for an installation of electric light under the direction of parochial committees.

Leominster.—The matter of electric lighting is said to be among the subjects coming before the Town Council shortly.

Liverpool.—The Liverpool Corporation is raising a million-and-a-half loan. That sum includes £600,000 paid for the tramways, £50,000 for the experimental electric tramway, and £400,000 raised under the Electric Supply Act, 1896.

London.—On Thursday evening last week, Mr. Robert Hammond read a paper on "Electric Lighting" to the members of the City of London Tradesmen's Club, at the Albion Hotel, Ludgate Circus. A great many surveyors and engineers of local Vestries in the Metropolis were specially invited to take part in the discussion which followed. Mr. Hammond, in the course of an exhaustive paper, dealt particularly with the present electric lighting monopoly in the City, observing that the company now providing the electric light charged the maximum rate, viz., 8d. per unit, whilst at St. Pancras the charge was only 5½d., at St. James' 5½d., and at Kensington 5½d. He also said that the City company maintained a strict secrecy as to the number of units they supplied, in spite of the fact that by the Act of Parliament they were compelled to furnish an annual statement. From computations he had made, however, by means of the division of the revenue of the company by 8d. he found that the company had supplied during 1896 a total of 5½ million units. Now comparing that output with some of the other companies in the Metropolis, he thought the charge made by the City company was very unfair, because he found that companies with as small an output as 100,000 units only charged about 6d. The City Commissioners of Sewers were responsible for granting the present monopoly of City electric lighting, and the present arrangement was that until the company reached a 10 per cent. dividend, and cleared off the arrears of previous years, the consumers would have to continue paying 8d. per unit. The City company, he added, had quite recently issued £200,000 more ordinary shares, bringing the total of such shares to £600,000, and in consequence £60,000 a year had to be disbursed to the ordinary shareholders in dividends before the price could be reduced. In 1896 he found the profits of the year's working amounted to £67,000, out of which the ordinary shares ranked for a 7 per cent. dividend. The electric light company, he said, which supplied electric light to the Smithfield market area proposed to charge only 4d. per unit to the large consumers, and the smaller consumers 6d. In conclusion, he strongly urged the City authorities and other local bodies to put down their own electric lighting plant, and pointed out that it was possible to borrow money to attain that object at from 3 to 3½ per cent. with the repayments spread over a long term of years. A gentleman pointed out that the City street lamps were supplied at a charge of only 3d. per unit, but Mr. Hammond replied that these were arc lamps running all night, and did not require the same number of men to keep the work going. Mr. A. C. Morton, a member of the Corporation, said that the Court of Common Council had the matter before the Lighting Committee, and that he hoped before long to see an installation beneath the Guildhall, when the Corporation would compete with the present company, and supply electric light to all the large public buildings and other premises. The Corporation claimed the control of the streets within the City. An animated discussion followed, and eventually the matter was adjourned for further discussion at an early date. Mr. Hammond was cordially thanked for his paper.

The County of London and Brush Company is applying to the Board of Trade for power to change its supply of electricity from continuous to alternating currents, and recently applied to the St. George's (Southwark) Vestry for approval to that course, stating that the public would receive advantage from the change. A special committee is considering the matter.

Madrid.—A Madrid correspondent informs us that about the beginning of the present month the greater part of the district supplied by the Electricity Supply Company for Spain, Limited, was without light for 48 hours.

Margate.—The Corporation has arranged a special meeting for Tuesday, the 25th, to consider the advisability of opposing the application of the Isle of Thanet Gas Company for Parliamentary powers to supply electricity for the lighting of the town.

Motherwell.—The new shops of the Motherwell Bridge Company, Limited, at North Motherwell Farm, will have a complete system of electric driving and lighting. At the Dabnell Steel and Iron Works of Messrs. D. Colville & Sons, Limited, an electric power installation is in progress. A beginning has been made with a 100-H.P. unit, which will be used for driving the machinery, cranes, &c., of their new machine shop. This will be followed later on by two units of 500-H.P. each, which will provide current to drive all the auxiliary machinery in the mills, such as live roller gear, guillotines, plate shears, straightening machines, &c. The low-tension polyphase alternating current has been adopted, and it is expected that when the numerous small engines scattered about the works have been replaced by motors, a very large saving in fuel and cost of upkeep will result. Messrs. Selby Bigge & Co., Newcastle-on-Tyne, are the electricians for the work.

Newport.—The Corporation has decided to increase the salary of Mr. Copland, the engineer at the electricity works, and that of Mr. Taylor, the assistant engineer.

Oldham.—The estimated income and expenditure in connection with the supply of electricity for the year ending March 25th, 1898, shows an expected net profit of £1,600. The charges to consumers are to be reduced from that date.

Plymouth.—The Electric Light Committee has accepted a tender for the construction of the electricity station buildings.

Portsmouth.—At the Town Council last week the Finance Committee submitted a scale of charges and apparatus for testing electric light meters by the Corporation inspector. It was stated that all the meters would be tested before being issued to consumers. If, on a subsequent test, a meter was found to be incorrect against the consumer, the Corporation would pay the fee. If, on the other hand, the meter was correct, the consumer would have to bear the expense. The fee for removing the meter for testing was put at 5s. It was objected that the proposed fee was rather prohibitive, and it was pointed out that the Gas Company charged only a shilling for removing meters. Alderman G. Ellis, Chairman of the Electric Lighting Committee, remarked that the testing of the meters was a costly operation, and the fee suggested was based on the charges in other towns. The recommendation was referred back.

It is anticipated that the new machinery will soon be in working order. It is estimated that the engineering strike has cost the Committee fully £2,500 up to the present time, through loss of revenue, owing to being unable to carry out orders received, and to the payment of £300 to the sinking fund for money the loan of which has been sanctioned, but which it has up to now been impossible to employ. Despite this drawback, 456 new customers have been attached since Christmas, and 235 are waiting to be connected with the mains.

Reading.—The contract for supplying the handsome electroliers and other fittings, including the wiring of the Large Town Hall, Small Town Hall, Art Gallery, Museum, Public Library and Municipal Offices, comprising in all an equivalent of 2,500 8-C.P. lamps, was placed in the hands of Mr. Leo Sunderland, 39, Victoria Street, S.W., agent to the Brush Company. The current was switched on a short time ago, and the difference in the lighting arrangements have been much appreciated. This makes a good addition to the Reading Company's consumers.

Ripley.—An application from the General Power Distributing Company to provide an electricity generating station at Ripley, is to be opposed by the District Council.

Sheffield.—Last week, the recommendations of a committee—which we printed last week—*re* the proposal to purchase the undertaking of the Sheffield Electric Light and Power Company at the price offered by the company—namely, £220 of Corporation 2½ per cent. stock for every £100 of capital actually spent by the company, came before the Council. Several members spoke in favour of acquiring the undertaking at once, and the report was unanimously adopted. The final call of £1 per share has been made by the company, payment to be made by the end of the month. At this time the whole of the original capital of the company will be fully paid.

Smethwick.—The District Council will not consent to the Midland Electric Corporation for Power Distribution, Limited, making application for a provisional order to supply electric light to Smethwick, as that body is already applying for a provisional order for municipal plant.

Somerset.—Owing to the recent fire at the works of Messrs. T. H. Smith & Co., Ltd., situated on the River Parret, Somerset, Messrs. Massingham & Co., of this city, have received instructions to fit the entire building with a complete installation of the electric light. There will be two dynamos, one driven by water power and the other by steam.

Southampton.—At last week's Council meeting, the Electric Lighting Committee reported that the output for November was 24,240 units, being an increase of 8,970 units, or 58 per cent. over that of November, 1896. Owing to the general increase of output it has now become necessary to run the works continuously throughout the 24 hours. To do this the staff will have to be increased sufficiently to enable three eight hours' shifts to be worked. At present the only addition necessary is a third assistant engineer. The load on December 23rd was the heaviest on record, and required the whole of the plant to deal with it. In consideration of the extra work the engineers have performed since March last, a bonus of £10 is to be paid to Mr. Lee, and £5 each to Mr. Neame and Mr. Britton. The following tenders for the wiring and fitting for electric light at the electricity supply station were received:—Mr. H. M. Ashton, £387 18s. 6d.; Messrs. A. Fort, Lloyd & Co., £395; Messrs. Sanby and Co., £415; Mr. F. Shalders, £476. The tender of Mr. H. M. Ashton was accepted.

The Corporation want an assistant electrical engineer. See our "Official Notices."

Taunton.—The Electric Light Committee has been advertising for tenders for the supply of 1,500 tons of coal. During the month of December 99 16-C.P. lamps were installed; in November there were 52; and in October, 34. A scheme for a large extension is to come before the Council directly.

Wakefield.—Complaints are numerous in consequence of the non-completion of the electricity undertaking, the delay being due to the non-delivery of engines.

Walsall.—The Council will not agree to the proposed provisional order of the Midland Electric Corporation for Power Distribution, Limited, to supply electricity in the borough.

Wandsworth.—The lighting of the large and scattered premises known as the "Ram Brewery," was entrusted to Mr. Leo Sunderland, agent to the Brush Company. This is probably the largest installation of the kind in the district, comprising an equivalent of 750 8-C.P. lamps, and seven arc lamps. This installation will shortly be connected to the supply company's mains.

Water Power.—The famous falls of the Devon and grounds of Rumbling Bridge have, says the *Glasgow Herald*, been examined by electrical engineers with the object of utilising the water power to light the grounds and hotel by electricity. The engineers will be unable to proceed with the work till they ascertain the lowest summer level of the river. Should the scheme then be found practicable it is proposed to carry the water a short distance below the "Devil's Mill" in a two-feet pipe with a fall of 12 feet, which will give sufficient power to drive a dynamo to light the grounds, hotel, conservatory, stables, and outhouses.

Whickham.—A Committee has recommended the lighting of the Marley Hall district with electricity, 32 lamps being used. The price for the complete installation is £165, and the yearly charge of £55 4s.

Withington.—The proposal of the Manchester Corporation to supply this district with electric light has been considered by the Parliamentary Committee of the Withington Council, which recommends that an electrical expert be engaged to advise on the point. This recommendation has been sent back for reconsideration.

Wolverhampton.—It has been found, says our local correspondent, that the electricity turned out on Christmas Eve exceeded by 34 per cent. that turned out on the corresponding day of 1896. There is, of course, always a good demand at Christmas time, and it is reckoned at the head office that more customers are obtained at the Christmas quarter than during any other period of the year. It is now regarded as certain that the time cannot be far distant when the light will be extended over the entire borough. The new sub-station at Chapel Ash is rapidly approaching completion, and in a week or two's time it will be in working order. The mains will then be carried down the Tettenhall, Compton and Merridale Roads, where there are a large number of residential dwellings. An additional boiler is about to be put in at the Commercial Road works, and another new engine is shortly to be placed there.

The Town Council has resolved, by a majority of 25 to 8, to oppose the application of the Midland Electric Corporation for Power Distribution, Limited, for a provisional order empowering them to supply electricity within the borough of Wolverhampton.

Yarmouth.—During December the electric light receipts were £605 15s., and the expenditure £235 8s. 11d., leaving a surplus of £370 6s. 1d. to meet capital charges of £190 per month. There are now 255 customers with 11,938 lamps.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

Burslem.—The Council is giving notice to the British Electric Traction Company that proceedings will be taken against them if Scotia Road is not completed and opened for traffic within 21 days; and notice is to be given to the North Staffordshire Tramways Company, pursuant to their agreement with the Corporation, calling upon them to commence the electric equipment of their line within three months, or in default their agreement would be cancelled.

Chesterfield.—The Highways and Tramways Committee is considering the question of continuing the tramways to Whittington Moor and other parts of the district; also the matter of mechanical traction.

Dover Harbour Works.—It it stated in a Dover paper that there is likely to be a start made in March with the National Harbour Works, and it is understood that electricity is likely to be the motive power employed, current in all probability being taken from the Dover Electricity Company.

Dover Trams.—The *Dover Standard* is responsible for the statement that with the Maxton section of the electric tramways now running, the amount of current being taken from the company is not likely to exceed the minimum arranged under the contract at the commencement of the running. The current required for the extra cars and quicker service is included in this estimate.

Dublin.—The Kingston Commissioners have discussed the proposed alteration in the electric tramway line through Upper and Lower George's Streets. A resolution, detailing an interlacing system between St. Michael's Hospital and the People's Park has been agreed to.

Dudley.—Mr. Reginald P. Wilson has been instructed to report to the Dudley Corporation as to the cost of buying the existing tramway to Hart's Hill; and also to furnish estimates as to the cost of equipping this and other proposed tram lines on an electrical system.

Ealing.—There is quite a lengthy correspondence in the *Middlesex County Times* respecting the London United Tramways Company's proposed electric tramway scheme, which the District Council has opposed so strenuously. Many of the writers are greatly surprised at the action of the Council.

Electric Traction on the Continent.—The *Financier* says that a powerful French company has addressed a simultaneous request to the Governments of France, Belgium, and Holland, for powers to establish a system of electric traction along the navigable highways of the three countries, so as to form an international network extending from the Rhine, through Holland, and as far as Marseilles through the Eastern departments of France, making use, for the purpose, of the navigable highways of the three countries. It is stated that the "Banque de Paris et des Pays Bas" is interested in the enterprise.

Electric Transmission of Power.—A meeting of the members of the South Staffordshire Institute of Iron and Steel Works' Managers was held on Saturday at the Dudley Institute, when a paper on "The Application of Electricity to the Transmission of Power" was read by Mr. H. W. Ravenshaw. The writer pointed out that managers of works and manufacturers generally were beginning to realise the fact that the old methods of transmission of power to their machinery were in many cases extremely wasteful, and that the electric motor is far cheaper in the end than the line shafting and isolated steam engines which have been generally employed. In an engineering works, mill, or colliery, immense quantities of coal are uselessly consumed in wearing out belts and bearings, and in raising steam which is to be condensed in long lines of pipes and perhaps re-evaporated in the cylinders without any useful purpose. In order to reduce these losses as far as possible electricity is being employed in many cases with great success, a central station being established in the works, and electric motors being employed to drive the machinery. With this arrangement the boilers could be concentrated, high pressure could be safely used, and the labour and coal consumption reduced to a minimum; short steam-pipes carried the steam to economical engines which drive dynamos, supplying the necessary light and power to the works. In America and on the Continent multipolar dynamos are generally used, but in England up to the present the simple two-pole machine has been usually employed. The question of pressure to be employed was an important one. In collieries 500 volts are frequently employed, and with this pressure several hundreds of horse-power could be transmitted without difficulty over a radius of at least one mile. In a works covering a comparatively small area, both lighting and power could be obtained from a 200-volt circuit with economy, incandescent lamps being now made to work up to 220 volts. A good many works and mills have been fitted for 100 volts, but there is no advantage in so low a pressure, while with 200 volts a very great saving is made in the cost of cables.

Electrical Power Distribution.—The members of the South Staffordshire Iron and Coal Masters' Association were to attend a meeting at the Queen's Hotel, Birmingham, yesterday, to hear from representatives of the Midland Electric Corporation an explanation of their scheme for supplying electrical energy for power and manufacturing purposes throughout South Staffordshire. Sir Benjamin Hingley, Bart. (chairman of the South Staffordshire Iron Trade), and Mr. C. B. Cochrane (chairman of the South Staffordshire Coal Trade), in issuing the invitations, express the feeling that the introduction of electrical energy into the district on a scale and for the purposes proposed should not only assist the trades now being carried on, but should be a powerful incentive to new trades to settle in the district, and thus increase its prosperity and rateable value. The Midland Corporation is prepared to enter into agreements to supply electrical energy for power or manufacturing purposes at 1d. per Board of Trade unit, and for lighting at the rate of 6d per unit for the first hour's use per day and 3d. per unit for each subsequent hour's use daily. The Corporation is also prepared to lay a comprehensive system of mains throughout the district, and to supply motors for hire, so that manufacturers can secure the advantages of electrical power at the minimum of capital outlay.

The Coseley District Council has resolved to give consent to the application of the Midland Electric Corporation for Power Distribution to the Board of Trade for a provisional order to supply the district.

Electrically-Driven Laundry Machinery.—Electric motors are employed at Alnwick Castle for the Duke of Northumberland for driving a large size washing machine, wringer, centrifugal dryer.

Light Railways.—The promoters of the Llanfair-Beaumaris light railway attended a meeting of the Menai Bridge District Council, and gave details of the scheme, the proposed speed and width of road. The line is estimated to cost £48,000. The Council will support the scheme.

The Essex County Council have passed a resolution strongly in favour of the construction of a light railway for Ongar, Dunmow, and Yeldham. The proposed line will be 27 miles in length, and will serve a purely agricultural district which is greatly in need of railway facilities.

Leeds.—A sub-committee of the Highways Committee is going to visit Glasgow *re* tramways.

Leith.—The Town Council has confirmed the proposal to purchase the tramways for £75,000.

Liverpool.—In connection with the purchase of the tramways by the Corporation, a proposal was before that body for the payment of £9,000 compensation to the solicitors of the tramways company for loss of net profits, and £1,200 to the auditors for ditto, through the transference. The proposition was not carried, the voting being 35 in favour of an amendment, and 11 against.

Last week there was a conference of the Lighting Committee and the Tramway Committee with regard to the utilisation of electricity as the motive power on the tramways, the lighting of the tramcars on the experimental line, and the extension of the electric mains throughout the city. A report was presented by Mr. Holmes, the electrical engineer, showing how the electric system could be applied to the tramway service, and the advantage that would probably result therefrom. The proposals included the establishment of a large new electric generating station near the Leeds and Liverpool canal, the outlay being £150,000. It was decided to refer the matter to Dr. Hopkinson.

Manchester.—It was stated last week that the Manchester Carriage and Tramways Company was inviting representatives from the various local representatives around Manchester to attend a conference on the subject of their proposed Bill for using electrical and mechanical power in connection with their tramways.

Middlesbrough.—A Middlesbrough paper in a recent issue mentions the marked progress that is being made with the preparation of the track for the electric tramways. Mr. Robert Smith, who had charge of the Dublin and Bristol construction work for the Imperial Tramways Company, is in charge here. The section between the Borough Hotel and the Ormesby Toll Bar, a distance of a quarter of a mile, was laid within eight hours, reckoning from the time of breaking up the roadway to getting in the setts.

Mines Drainage by Electrical Pumping.—Mr. J. B. Cochrane presided at the usual monthly meeting of the South Staffordshire Mines Drainage Commission on 5th inst., at Dudley, and in moving the adoption of the engineer's reports, said he understood that the Midland Electrical Power Company were seeking powers to supply electricity all through the district. They would undertake to supply, for manufacturing purposes, electricity at the rate of 1d. per Board of Trade unit, which was equal to 1 3 H.P. The question had been before several local authorities in the district, who did not quite see eye-to-eye with the company. Many were opposing the powers sought for by the company, on the ground that they would like to retain the power of supply themselves. That was reasonable enough, if the authorities were prepared to supply the electricity to manufacturers at something like the same rate that the company proposed to do it. He believed the company had approached the Dudley Corporation, who, he understood, could not supply electricity at less than 2½d. per unit, as against 1d. by the company; but they would see at once that it would be useless for the Corporation to propose the supply of electric power at 2½d. when the company could do it at 1d. per unit. He believed 18 local authorities were comprised in the area which the company proposed to supply, and it was easy to understand that whilst the company would be able to put down economical plants to supply particular areas, each of the local authorities would have to put down a separate and costly plant. He took it that the local authorities had no desire to hinder the progress of manufacturers, and if they could not do it at less than 150 per cent. more than the company, then it became a question whether the authorities should not stand aside and let the company do the work. The scheme had a most important bearing upon the work of the Commission, and the scheme for unwatering the Tipton district. They would be able to pump the water from the surface at various points by electric power, and the cost would be very small indeed compared with what it cost to pump it out of the mines. It would probably save contemplated expenditure of between £30,000 and £40,000 in the Tipton district, and they could understand what an important consideration that was at a time when they scarcely knew how to go on and face the large expense of pumping a district overloaded with water.

Motor Dust Carts.—The Hackney Vestry has deferred for six months the further consideration of the proposal to consider the advisability of adopting carts and vans driven by electrical or other automatic motors.

Motor Mail-Carts.—The *City Press* says that it is stated that the chief executive officials at St. Martin's-le-Grand are so satisfied with the experimental motor-car (steam) that runs between London and Redhill that we may shortly see the introduction of a small *electric* letter mail van.

Norwich.—The Norwich tramways are not yet begun, says the *Norfolk Standard*, and we shall not be able to chronicle work in progress for another two months at least.

Portsmouth.—The Town Council last week confirmed its recent resolution authorising the promotion of a Bill in the ensuing Session in reference to the acquisition of the local tramways.

South Staffordshire.—At the last meeting of the West Bromwich Council, a letter was read from the Board of Trade, enclosing a correspondence which had taken place with the South Staffordshire Tramways Company. The latter company had applied for a further extension of time for the use of steam on the tramways, but the Board of Trade express regret that the arrangements for the re-equipment of the lines had not taken place, and that a new method of traction had not been completed. They would grant a further extension for a period of three months, but they warned the company they must not rely upon obtaining any further extension of time.

Southport.—The Town Council has adopted the recommendation of the Tramways Committee to make application for a provisional order enabling the Corporation to lay four miles of tram lines to Blowick, with subsidiary lines forming a connection with the line to the new infirmary, and thus providing a circular route. It was proposed to adopt overhead electric wires and single deck cars, and to greatly extend the tramway system in the future.

Suggested Electric Tramway.—A correspondent of the *Surrey Advertiser* suggests a conference between experts of the Town Councils of Guildford and Godalming and the Milford Parish Council to consider whether it might not prove profitable—as it certainly would be a convenience to the public—to establish an electric tramway between the three places, with branches extending up Sandy Lane to the immediate vicinity of Charterhouse and the building land under development thereabouts, and perhaps also to the Farncombe Station from the Portsmouth Road.

Sydney.—An Australian contemporary remarks that the generators, accumulators, &c., for the Rose Bay electric tramway are now being erected at the Rushcutter Bay Power House, Sydney. The survey has been completed. Tenders for the construction of the permanent way are being invited.

The Charing Cross, Euston, and Hampstead Railway.—The Charing Cross, Euston, and Hampstead Railway Company have deposited a Bill for powers to extend their authorised line from a point under Charing Cross Road, near the Garrick Theatre, to a point under No. 23, Craven Street, Strand. This extension is to be in substitution for the authorised Charing Cross terminus, which it is proposed to abandon. The Bill also seeks an extension of time until August, 1902, within which to construct the line as authorised in 1893, subject to the new terminus now proposed. Power is also sought to enter into agreements with the South-Eastern Railway Company and the London and North-Western Railway Company as to the working, management, and maintenance of the railway when completed.

Waterloo and City Electric Railway.—This line will shortly be opened for traffic. The line itself was completed some time ago, says the *Times*, but delay which could not be avoided has occurred both by reason of the dispute in the engineering trade, and also in connection with the enormous amount of underground work which has had to be undertaken by the Central London Railway Company at the new station opposite the Mansion House.

Whitechapel and Bow Proposed Railway.—A meeting of the London, Tilbury, and Southend Railway will be held on February 3rd to lay before the shareholders the proposed Bill for the construction of works and purchase of additional lands, also to subscribe towards the undertaking of the Whitechapel and Bow Railway Company, or to guarantee interest on the capital of that company.

TELEGRAPH AND TELEPHONE NOTES.

African Trans - Continental Telegraphs. — The *Rhodesian Times* for December 17th stated that that part of the Trans-Continental Telegraph which is now being carried up northward from Umtali towards the Zambesi, and will join the line which has already been set on the farther side of the river, will, if all goes well, be finished about April next. It is expected at Blantyre that the line northward will reach Karonga about the same time—that is, Cape Town will be in direct telegraphic communication with the northern end of Lake Nyassa, 10° south of the equator. And at the same time the southern point of the telegraph line in Egypt will be about 15° north of the equator. Thus, to complete this extraordinary work, there will only remain some 25° of latitude to be crossed, and in that distance Uganda lies midway. Mr. Rhodes' wonderful dream is becoming more and more of a tangible reality.

Australian Cable Service.—Several letters have appeared in the *Financial Times* during the past few days complaining bitterly of the inefficiency of the telegraph service between this country and Australia, which subject we have ourselves dealt with on many occasions.

Delays in Australian Telegrams.—We have again to place upon record two cases of interruption and delay in the Australian land line service. As we have pointed out on former occasions, this information is gathered from press notices, and thus, doubtless, there are many occurrences of this nature which escape our notice. Were the Postmasters of South Australia and of West Australia to act up to their duties towards the Bureau International des Telegraphes, it would spare us the doubt which we sometimes feel that we have omitted to register some of the interruptions which should be reported to the Bureau for the common convenience of all interested in telegrams. The following extract from the *Melbourne Age*, of November 20th, has only just reached us:—

"The Telegraphic Service. A Far-reaching Block. Business Paralysed.

"The telegraphic system suffered very severely by the storm, and all last night the lines were in a chaotic state. Telegraphic business from the Melbourne office was completely paralysed. It was possible to communicate with Geelong and Ballarat, and with stations on the North-Eastern line, by which Sydney is reached, but Adelaide and intermediate stations, together with other trunk lines and the Tasmanian service, were completely silenced. The central authorities, indeed, state that such disastrous results have never before accrued from any storm. The public, unfortunately, will suffer serious inconvenience from the vagaries of the wind and lightning, as the operators have before them large piles of messages ready for despatch, but are absolutely prevented by the wrecked state of the lines from sending them out. Worse still, the line repairing department is, so far, unable to estimate, even approximately, the time at which the service can be resumed. Gangs of line men have been sent out in all directions, however, and the work of repair will be pushed on with all possible speed, and the operations of the repairers will, as rapidly as possible, be extended into the remote districts where it is known bad breaks have occurred."

We also gather from the press that, on Saturday week last, "in consequence of the Australian land lines working badly," no cables reached an important firm of London brokers.

Interruption of Australian Land Lines.—In the absence of information from Berne, we have to thank the Singapore press of December 13th last for the following:—"The South Australian land lines between Port Darwin and Adelaide are interrupted by heavy floods at the Katherine, 15 inches of rain having fallen in a little over 24 hours. Everything is being done to restore communication as soon as possible. The lines *via* Roebuck Bay and Western Australia are working well."

Paisley Telephones.—The National Telephone Company has asked the Council to appoint a committee to meet representatives to consider the question of certain improvements in the telephone system, such as the placing of the twin wire or metallic return system. The matter will be considered by the whole Council in committee.

The Bermuda-Jamaica Cable.—The Direct West India Cable Company announces the completion of its cable from Bermuda to Turk's Island, thereby establishing telegraphic communication with the latter colony. Messages can now be accepted in Great Britain and Ireland at the rate of 3s. a word. The cable steamer is now laying the company's cable from Turk's Island to Jamaica, and it is expected to be completed well within the contract date, namely, 31st inst.

The Pacific Cable.—The *Times* of Tuesday has an article discussing the Pacific cable scheme in relation to the Colonies. It is considered that in view of the developments taking place in the Far East, the project of an all-British Pacific cable connecting the British Colonies of the North with those of the South Pacific acquires fresh importance. After dealing with the history of the proposal, the writer says:—"In the summer of last year the question again formed a subject of discussion in the conferences of Premiers held at the Colonial Office, and again no formal information was given to the public as to the result of the discussion. An informal statement was, however, made, and though unauthorised, has been since confirmed from Colonial sources in a way which leaves little doubt of its authenticity, that the position as to the construction of the cable was entirely changed by the proposal of the Eastern Extension Telegraph Company to lay an all-British line from Western Australia across the Indian Ocean to Mauritius, thence connecting with the Cape and St. Helena and Ascension. The proposal appears to have been submitted to the consideration of the Colonial Premiers as a substitute for the Pacific cable. Here, then, so far as the history of the movement can be summarised in a few words, the situation rests. As between a Pacific cable, for which they will be asked to pay, and an all-British Eastern Extension line connecting Africa with Australia, for which they will only be asked to make indirect concessions, Governments, with the fear of the Treasury before their eyes, hesitate to commit themselves to the support of the Pacific cable scheme." Dealing with the future, the writer says:—"Every sign would seem to indicate that the coming 20th century will be celebrated in the history of the world by the development of a new civilisation on the Pacific. To affirm the legitimate position of Great Britain in that civilisation must be the object of British policy, and for this purpose cheap and rapid means of communication between the local British centres is one of the first of necessary conditions. This aspect of the question is not dealt with by any proposals for cable construction that exclude the Pacific Ocean from their scope." . . . . "The estimated cost of the cable is not great, and it is difficult to comprehend that the construction can have been so long delayed." The *Daily Mail* of January 19th states, under date Montreal, January 18th, that interest in the all-British Pacific cable has been revived by events in the East, and that Sir Sandford Fleming has published an open letter to Sir Wilfrid Laurier reviewing the history of the project, and calling upon Canada to take the initiative at once.

A Cape Town despatch says that a deputation of the Afrikander Bond, headed by Mr. Hofmeyr, presented last Friday an address to Sir Alfred Milner, Governor of Cape Colony, representing the urgent necessity, in the interest of Imperial defence, of an all-British deep-sea cable. His Excellency, in reply, said he was not acquainted with the views of the Imperial Government on the subject, but he promised to forward the address to England.

The Telephone Service.—The *Daily Mail* has learned "on authority which it believes to be reliable that the Post Office has already come to a very important decision with regard to the telephone question. It hears that the Post Office inquiry into the request (for a license) that came from the city of Glasgow has resulted in an official report confirming the old attitude of refusing to grant any fresh licenses. The Post Office, it understands, takes up the position that the telephone system is on all fours with the telegraph system, that it should not be allowed to fall into local hands, for fear that systems under different regulations and possibly making different charges should be established in separate localities. The Post Office claims that, like the telegraph and penny post, the telephone system should be uniform in its charges and regulations." We are unable to obtain any confirmation of this intelligence, but since the reasons mentioned conform to those publicly advanced on behalf of the Post Office, and, moreover, agree with public policy, we should not be surprised if the information proved to be correct. But where is Sheriff Jamieson's report?

CONTRACTS OPEN AND CLOSED.

OPEN.

Ashton-under-Lyne.—February 2nd. The Baths Committee want tenders for the installation of the necessary wires and fittings for the electric lighting of the Corporation Baths. Consulting engineers, Messrs. Lacey, Clirehugh & Sillar. See our "Official Notices" last week for particulars.

Bilbao.—February 28th. The Secretary of State for Foreign Affairs has received a despatch from Her Majesty's Consul at Bilbao, reporting that the provisional board appointed in connection with the electric tramway which it is proposed to lay from Zumarraga to Zumaya, in the province of Guipuzcoa, invite plans and tenders, to be received by February 28th, for the construction and equipment of the line. Further particulars of the conditions of the tenders for the above-named tram line and branch, which together measure 30 miles, may be inspected at the Commercial Department of the Foreign Office any day between the hours of 11 and 6.

Bedford.—January 24th. The Corporation want tenders for the supply and delivery of vulcanised rubber cables. See our "Official Notices" January 7th.

Belgium.—February 11th. The Provincial Government Authorities in Brussels are inviting tenders for an installation of electric lighting in the offices of the Governor of Brabant in the Rue de Chêne, Brussels. Tenders to be sent to the Gouvernement Provincial, Brussels.

Berlin.—March 15th. The Municipal Traffic Deputation of the Town Council have opened a competition for the construction of several new electric tramways in that city. Exhaustive details concerning this project are contained in the *Elektrotechnische Zeitschrift* of the 13th inst., which mentions that proposals will be received by the Stadtische Verkehrsdeputation Rathhaus III, Berlin, by March 15th.

Blackburn.—January 22nd. The Corporation want tenders for a 500-kw. continuous current steam dynamo, and a 120-kw. steam alternator. Consulting engineer, Mr. E. M. Lacey. See our "Official Notices" January 7th.

Bradford.—February 1st. The Corporation is inviting tenders for the electrical equipment of about nine miles of street tramways. There are three contracts for the following sections:—(1) steel poles, bracket arms, &c.; (2) trolley wire, insulators and overhead equipment; (3) cars, trucks, motors and trolley poles. Particulars from the city surveyor or the city electrical engineer at the Town Hall.

Brighton.—January 31st. The Town Council want tenders for dynamos, motors, switchboards and wiring for the electric lighting of the Municipal School of Science and Technology. Specifications from the town clerk's office.

France.—January 22nd. The Municipal Authorities of Neuilly-sur-Seine are inviting tenders for the concession for the establishment and working of a central electric station in the town. Particulars from, and tenders to, La Mairie de Neuilly-sur Seine.

France.—March 31st. Tenders are being invited by the Municipal Authorities of Saint Chamond (Loire) for the concession for the lighting of the public streets of the town, either by gas or electricity. Particulars from, and tenders to be sent to, La Mairie de Saint Chamond (Loire).

Germany.—January 29th. The Hanover Direction of the Prussian State Railways is inviting tenders until the 29th inst. for the supply of 39,000 porcelain insulators, 1,000 screw supports, 300 tons of galvanised wire and about 2¾ tons of insulated wire. Particulars from, and tenders to, Die Königliche Eisenbahn Direction, Hanover.

Leicester.—January 31st. The Leicester Corporation invites designs and tender for motor vehicles for the collection of house refuse. Specifications and particulars, with drawings, to be sent to the Chairman of the Sanitary Committee, to the office of Mr. E. Geo. Mawbey, C.E., borough engineer, Town Hall, Leicester.

Newport.—January 24th. The Electricity Committee want tenders for the supply and erection of mains, transformers, switch gear, cast-iron posts and for arc lamps. Consulting engineer, Mr. Robert Hammond. See our "Official Notices" January 7th.

Newport.—January 25th. The Corporation want tenders for temporary electric lighting plant for the Wentwood Waterworks, for arc and incandescent lighting. See our "Official Notices" January 14th.

Rochdale.—February 19th. The Corporation want tenders for steam dynamos, balancer, and boosters, &c. Engineers, Messrs. Lacey, Clirehugh & Sillar. See our "Official Notices" January 14th.

Roumania.—March 15th. Tenders are being invited by the General Direction of the Roumanian Post and Telegraphs in Bucharest for the supply of 56,000 metres of galvanised iron and steel wire.

Spain.—February 1st. Tenders are being invited by the Municipal Authorities of Tarifa (Cadiz province) for the 20 years' concession for the lighting of the public streets of the town by electricity, acetylene or gas. Tenders to El Secretario del Ayuntamiento de Tarifa (Cadiz) from whom particulars may be obtained.

Spain.—February 8th. Tenders are being invited until February 8th by the Municipal Authorities of Tordesillas, a small town in the province of Valladolid, for the concession for the electric lighting of the public streets during a period of 20 years. Particulars may be obtained from, and tenders should be sent to, El Secretario del Ayuntamiento de Tordesillas (Valladolid).

Stockport.—January 27th. The Corporation is wanting tenders for various plant and machinery for electricity supply works at Millgate, Stockport, including Lancashire boilers, steam dynamos, feed water heater, storage battery, electrical instruments, electrical connections, wiring, &c., at the generating stations, underground cables. Electrical engineer, Mr. James N. Shoolbred, 47, Victoria Street, S.W. See our "Official Notices" January 14th.

Wimbledon.—February 2nd. The District Council wants tenders for the supply, delivery and erection of water tube boilers, condensing plant, overhead crane, high speed steam engine and alternator, switchboard, underground mains, conduits, &c. Consulting engineer, Mr. A. H. Preece. See our "Official Notices" January 14th for particulars.

CLOSED.

Barrow.—The minutes of the Electric Lighting Committee, which were adopted by the Council the week before last, contained recommendations to accept the following tenders, which had been reported upon by Mr. Manville, for the electricity supply undertaking:—

Buildings.—W. W. Fairbairn	£8,386
Section A.—Babcock & Wilcox	5,050
" B.—Brush Electrical Engineering Company	9,332
" C and D.—British Insulated Wire Company	(schedule prices)

These tenders have accordingly been accepted.

Derby.—The Council has accepted the tender of Messrs. S. Z. de Ferranti, Limited, for engine and dynamo at £7,132 10s. Several hundred yards of cable has been ordered for extensions at a cost of £132 14s.

France.—A contract for the construction and working of an electric tramway between Angoulême and Ruelle (Charente) has been secured by the French Thomson-Houston Company.

Leith.—By four votes to three the Town Council has given the contract for the supply and erection of steam dynamos, &c., for the electric lighting of the burgh for the sum of £8,844 to the India-Rubber, Gutta-Percha and Telegraph Works Company.

London.—From the list of tenders submitted to the Metropolitan Asylums Board for the alteration and extension of the electric fire alarm system at the South Eastern Hospital, that of the Private Wire and Telephone Installation Company at £122 10s. was selected for acceptance. The highest tender was £387 10s.!

London.—The tender of Messrs. Bergtheil & Young has been accepted for the electric wiring of the extensions of the Guildhall School of Music.

FORTHCOMING EVENTS.

1898.

Friday, January 21st, at 5 p.m.—Physical Society, at the rooms of the Chemical Society, Burlington House. Agenda:—(1) "On Electric Signalling without Conducting Wires," by Prof. O. Lodge, F.R.S.; (2) A Tesla Oscillator will be exhibited by Prof. S. P. Thompson, F.R.S.

At 8 p.m.—Institution of Junior Engineers, at the Westminster Palace Hotel. Lecture on "Laboratory Testing Machines, and the Latest Example," by Prof. A. C. Elliott, M.Inst.C.E., Hon.M.Inst.J.E., of Cardiff.

Saturday, January 22nd, at 3 p.m.—Institution of Junior Engineers—Visit to the Engineering Laboratory of the Central Technical College, South Kensington. Demonstrations by Prof. W. C. Unwin, F.R.S., Past Pres. Inst.J.E.

Latest date for receipt of Blackburn Corporation tenders.

Monday, January 24th.—Latest date for Newport and Bedford tenders.

At 8 p.m.—Northern Society of Electrical Engineers. Palatine Hotel, Hunt's Bank, Manchester. Paper by Mr. W. P. Adams on "The Cost of Heating and Cooking by Electricity."

Thursday, January 27th.—Latest date for Stockport tenders.

At 8 p.m.—The Institution of Electrical Engineers "Notes on the Electro-Chemical Treatment of Ores containing the Precious Metals." By Major-General Webber, C.B. (ret. R.E.), Past President.

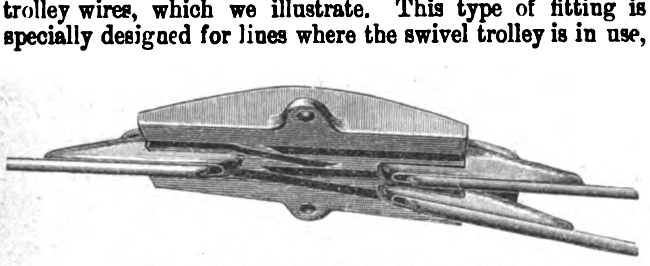
Friday, January 28th, at 8 p.m.—The Institution of Civil engineers. Students' meeting. Paper to be read on "Condensing Apparatus," by H. Williams, Stud.Inst.C.E.

NOTES.

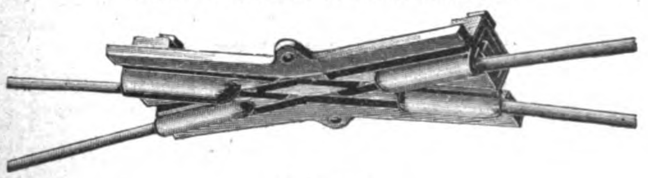
The Damage Due to the Strike.—The Board of Trade returns for December show a falling off, as compared with the same month of 1896, on steam engines from £313,069 to £188,809, and in other machinery from £1,207,930 to £909,339, or a total for the month of £422,851. On making the same calculation for the year, one-half of which was occupied by the strike, the total falling off comes to £732,165, made up of a drop on steam engines from £3,286,353 to £3,040,073, and in other machinery from £13,727,897 to £13,242,012. The total for the year is not double that of December, which month we may set down as merely showing an accidentally large reduction. Obviously the figures for the whole year are safer guides. As there have been other causes than the strike to operate unfavourably during the past year, it may be considered that the strike has, in six months, reduced the exports about £750,000. If one-fifth of this amount would count as profit, and if the wages paid amount to five times the profit, then the loss in wages is just £750,000. The employers have lost £150,000 on this basis, and the men have lost the three-quarters of a million and spent their reserve funds. In six months the falling off has been about 6 per cent. of the year's total, or at the rate of 12 per cent. of six months' output. The figures are bad enough, it is true, but they are not hopeless. Every week is increasing the productive capacity of the fresh hands as well as their number, and the prospects are that, strike or no strike, the present year will show that amalgamated engineers, as such, are not necessary to the employers. No man can be of much use to himself, his country, or his family, for an indefinite period, who orders his goings, or allows others to so order them, in direct contravention of the laws of nature, of common sense, or of common honesty.

Enclosed Arc Lamps.—Mr. W. H. Freedman concludes an article on this subject in the *American Electrician* as follows:—Besides direct-current enclosed arcs, there are now on the market several makes of alternating enclosed arcs. These have the advantage over the open that the energy employed at the arc may be a higher percentage of the total energy supplied than in the direct. They, however, work best at one particular frequency, which might be in some cases a serious objection. In general, the enclosed arc lamp as compared with the open has the following advantages:—Long life, and consequent saving of carbon, trimming expenses and annoyance from frequent renewals; pleasant light, free from hissing and spluttering, and with very little flickering; absence from flying dust and sparks, and fireproof qualities resulting from the use of two globes; being run on the incandescent circuit, there is no danger from high potentials, and no need of an automatic cut-out; simplicity of mechanism, and, consequently, less need of repairs. Ability to instal only one lamp and not necessarily two. Against the above are, however, to be balanced the disadvantages of lower efficiency, and decrease of light with the time of running.

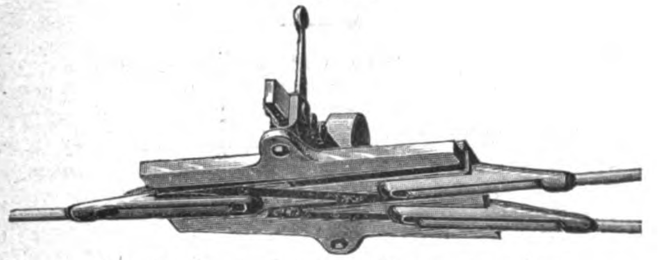
Overhead Wire Construction.—Mr. W. Wood, engineer-in-charge of the Bristol electric tramways, has devised an improved frog, crossing and movable point for overhead trolley wires, which we illustrate. This type of fitting is specially designed for lines where the swivel trolley is in use,



FROG: TWO LINES RUNNING INTO ONE.



CROSSING.



MOVABLE POINT: ONE LINE RUNNING INTO TWO.

the Bristol line being completely equipped with them. The chief feature about the device is, that after the trolley leaves the wire it is guided across the plate by a groove which fits the external diameter of the trolley wheel, and makes a positive path.

Institution of Mechanical Engineers.—The annual general meeting of this institution will be held on Thursday evening, February 10th, and Friday evening, February 11th, at 7.30 p.m., at 25, Great George Street, Westminster. The annual report of the council will be presented to the meeting on Thursday. The retiring president, E. Windsor Richards, Esq., will induct into the chair the president elect, Samuel W. Johnson, Esq. The adjourned discussion will be resumed on the Thursday evening upon the following paper read at the last meeting:—"Mechanical Features of Electric Traction," by Mr. Philip Dawson. Among the papers which will be read and discussed, is "First Report to the Gas Engine Research Committee: Description of Apparatus and Methods, and Preliminary Results," by Prof. Frederic W. Burstall, of Birmingham.

Munro & Jamieson's Pocket-Book of Electrical Rules and Tables.—We are pleased to learn that a 13th edition of this indispensable electrical engineers' pocket-book has been called for, but we hope that the authors and publishers may see their way to reduce its bulk, which has been gradually assuming undue corpulent proportions. We are sure that the authors would appreciate the advice and suggestions of any of our readers as to where they should omit old matter, and where they can, with advantage, insert new data.

Webb Testimonial Fund.—It is intended to make the presentation at a subscription dinner to be given to Mr. and Mrs. Webb by contributors to the Testimonial Fund, on Monday, February 14th, at the Whitehall Rooms of the Hotel Metropole. Tickets may be had from the hon. secretary of the fund, Mr. Henry Edmunds, 39, Victoria Street, Westminster, S.W., the price of single tickets being £1 1s.; and that of double tickets (for a lady and gentleman) being 36s.

Electrical Units.—A Bill is about to be introduced in the German Reichstag concerning electrical units of measurement.

Polyphased Armature Windings.—In another column will be found the first part of an interesting article by Mr. J. P. Stone (*American Electrician*) on the windings of polyphase armatures, which should go far toward dispelling the idea held by many that such windings are especially intricate. As will be seen, says our contemporary in an editorial note, the Y-winding consists merely of two ordinary alternator windings in the case of two-phased machines, or three such windings in the case of three-phased machines. Two-phased windings are entirely disconnected on the armature, an analogy to such a machine, therefore, being two simple alternating-current machines with their shafts rigidly connected, and corresponding wires displaced with reference to the poles, by half the distance between poles. A similar analogy to a Y-wound three-phased machine would be three simple alternators with their shafts rigidly connected, with corresponding wires displaced a third of the distance between poles, and with three collector rings—one ring of each of the three pairs of rings—connected together. The delta winding is merely the usual direct-current winding, tapped at four equidistant points for two-phased working, or at three equidistant points for three-phased working. As pointed out by Mr. Stone, the selection of either type of winding for polyphased machines is merely a matter of convenience. Where a neutral wire is to be run from a three-phased machine, the Y-winding must be used, the neutral running from a fourth collector ring being connected to the common point of the three windings. Such a neutral will supply three additional circuits of a lower voltage than that of the main circuits; that is, if the voltage between the neutral wire and the three main wires is 1,000, the voltage between the three mains will be 1,732. By placing three rings on the commutator of any direct-current machine, the rings being electrically connected to three equidistant bars, the machine will be a three-phased, delta-wound alternator, so far as generating alternating current is concerned.

Storage Battery Traction in Chicago.—The Englewood and Chicago Electric Street Railway Company has been actually in operation exclusively by storage batteries for slightly more than one year, and its cars have just completed 400,000 miles of service. This road, says the *Street Railway Journal*, was built in the most solid and substantial manner expressly for storage battery work. Late in 1896, a few cars from the Madison Avenue (New York City) line were put in service, but it was not until January 1st, 1897, that the first lot of new cars, built expressly for the road, commenced running. This number was increased as rapidly as possible, and last summer, on the heaviest days, 20 30-foot motor-cars, each with a trailer, have been required. The company owns 44 sets of batteries, and up to the present time these batteries have averaged nearly 9,500 miles of service each, the maximum being about 13,500 miles. So far, says our contemporary, there is no perceptible depreciation of the plates, and to all appearances they have yet a long lease of life. Nothing has been spent on maintenance account. The receiver, G. Herbert Condict, states that the entire operating expenses of the road in 1897 amount to but 8 cents per car mile, or 8½ cents including the expenses of the receivership. This is an extraordinarily low figure, even for a trolley line, and one which has never hitherto been approached in storage battery work. The cars run about 200 miles each per day, which is responsible for the low cost per car mile of "car service" labour. Mr. Condict, who is most fair and conservative in his statements, is unwilling as yet to say positively that storage battery traction is on this road cheaper than the overhead system would be, but says that if the batteries, which, as before stated, are apparently in as good a condition as when first installed, will last for 8,000 to 10,000 miles more, a distinct economy in comparison with the overhead system would be shown.

Obituary.—We regret to hear of the death of Mr. Wm. Patterson, of the City Wire Works, Walkergate, Newcastle-on-Tyne, whose change of address we notified last week. Mr. Patterson's death occurred on 11th inst. The business will be continued by Mrs. Patterson, under the management of Mr. Scott.

Lectures.—A course of 12 lectures is to be given at Honiton on "Magnetism and Electricity," under the auspices of the Devon County Council, by Mr. F. Brett.

Royal Institution.—Prof. J. A. Fleming is to deliver a series of five afternoon lectures on "Recent Researches in Magnetism and Diamagnetism" in March, as follows:—Thursday, March 3rd, "Ferro-magnetism;" March 10th, "Para-magnetism;" March 17th, "Diamagnetism;" March 24th, "Thermo-magnetism;" March 31st, "Magnetic Theories."

Appointment Vacant.—The Barrow-in-Furness Corporation are advertising for a resident electrical engineer at £200 per annum, to take charge of the electric light undertaking. See our "Official Notices" for particulars.

The Royal Society.—Among the papers down for reading yesterday afternoon were:—Prof. W. Ramsay, F.R.S., and Morris W. Travers, on (1) "The Homogeneity of Helium;" (2) "Fergusonite, an Endothermic Mineral." T. Preston, "On the Modifications of the Spectra of Iron and Other Substances radiating in a Strong Magnetic Field."

Marriage.—On January 11th, Mr. Tom Hesketh was married to Miss Fanny T. Dewhurst at Christ Church, Southport. Mr. Hesketh was, until very recently, assistant electrical engineer at the Hampstead Electricity Works.

Paper.—Before the Newcastle Students' Association of the Institution of Civil Engineers, a paper was read on 12th inst., at the Durham College of Science by Mr. John F. C. Snell, on "The Advantages of Direct Current Supply from Central Stations."

Such is Life!—"It may be that not to know Mr. Yorke, electrical engineer, of Glasgow, argues oneself unknown, but I must plead guilty to not having heard of the gentleman a week ago." So writes the editor of a contemporary who usually implies that what he doesn't know is not worth knowing. And yet the columns of the Electrical Review have for some years past testified to the existence of Mr. Yorke.

Electric Launches.—Mr. Justus Eck writes as follows respecting our recent note on "Electric Launch for the Czar of Russia":—"It may interest you to know that at the same time an order was placed in America for the above, another was placed in this country with Messrs. Kerby Bowen, Limited, and that this is now being built in the Isle of Wight, under the supervision of the Naval Attaché of the Russian Embassy in London. Many new ideas are being incorporated in this launch, but those responsible for the same do not intend to point out their advantages till they have been approved by practical experience. This order probably followed from the construction by the above company of successful launches for German, French and Austrian steamship and armament companies, and private (and sometimes Royal) individuals, not to speak of British customers. It will be of interest, when the time arrives, to compare the relative advantages of the launches, one all American, and the other all English manufacture."

CITY NOTES.

The Yorkshire House-to-House Electricity Company, Limited.

We have more than once congratulated the admirably managed Leeds Company upon the smartness with which it issues its annual report. Not only do we again compliment the managers upon the celerity with which they have presented the statement of affairs to the proprietors, but we must also draw attention to the extremely low cost of production which has marked the conduct of the business. We thought that Mr. Dickinson did something very noteworthy last year when he showed the cost per unit to be 1·65d., but that figure has now been decreased by ·23d., the total cost per unit during 1897 being 1·42d. and the works' cost 1·02d. The following are the chief points in the directors' report:—

"The profit for the year, after transferring £2,300 to the depreciation fund account, amounts to £10,703 1s. 11d., to which is to be added the sum of £392 12s. 2d. brought forward from the previous year, making a total of £11,095 14s. 1d., which the directors propose shall be appropriated as follows:—

To reserve fund account		£3,000 0 0
" Payment of interim dividend at the rate of 5 per cent. per annum on the amount called and paid up on the ordinary shares of the company, for the half-year ending June 30th, 1897	£2,624 8 1	
" Payment of a dividend on the amount called and paid up on the same shares, which, with the interim dividend previously paid, will equal a dividend at the rate of 6 per cent. per annum for the year ending December 31st, 1897 ...	4,142 3 7	
		6,766 11 8
" Balance to carry forward to next account		1,329 2 5
		£11,095 14 1

"The company's works and plant have been maintained in a thoroughly efficient state of repair.

"The number of lamps connected to the mains, which, on December 31st, 1896, was equivalent to 39,396 35-watt lamps, had increased by December 31st, 1897, to 49,150 such lamps.

"In accordance with the resolution passed at the last general meeting, 18,948 ordinary shares were, on February 2nd, 1897, offered at par to the then existing members of the company, and 18,626 shares were applied for and allotted. The directors carefully considered the suggestion made at the same meeting in favour of extinguishing the founders' shares in the company, but came to the conclusion that it is not yet practicable to effect such an operation.

"The company's new buildings are practically completed, and contracts have been made during the year for additional engines and alternators of a total capacity of 1,500 indicated horse-power (or 900 kilowatts). The greater portion of this plant is expected to be ready for use in a few weeks, and the remainder during the coming summer.

"A large expenditure has been incurred in the provision of improved means of distributing electrical energy in the central parts of the City. The mains have been considerably extended in the direction of Kirkstall, and an extension will shortly be made in Meadow Road.

"A reduction in the charge for electrical energy has been made, taking effect on January 1st, 1898, the maximum price having been reduced from 6d. to 5d. per unit. The charge previously made for connecting premises has been abolished, except in cases where the wires have to be carried exceptional distances, and the minimum charge of 13s. 4d. per quarter for current (authorised by the company's provisional order) is not now enforced. These modifications will represent a future total concession of several thousands of pounds per annum, but the directors decided upon them in the expectation of a compensating additional consumption.

"The Leeds Corporation have in contemplation the purchase of the company's undertaking."

The following table gives the cost per unit:—

	1897.	1896.
Total capital expended	£131,992	£105,377
Number of units sold	833,280	701,409

Total cost per unit (exclusive of depreciation and renewal accounts), 1·42d.; works' cost, 1·02d.

The Dividends for 1897.

Although so short a time has elapsed since the close of the year, announcements of dividends are already being made. One has for a considerable time looked upon the St. James' and Westminster in the nature of gilt-edged securities, and this view receives ample confirmation from the dividends just declared.

The following list gives the dividends announced, with the corresponding ones for the previous three years:—

London.	1897.	1896.	1895.	1894.
St. James' and Pall Mall	14½	10½	7½	6½
Westminster	12	9	7	5
Provincial.				
Yorkshire House-to-House Company...	6	6	5	4

The St. James' and Pall Mall Electric Light Company, Limited.

At an extraordinary general meeting of this company held at Carnaby Street, Golden Square, London, W., on Tuesday, the following resolutions were considered and adopted:—"That the agreement bearing date the 16th day of December, 1897, and made between the company of the first part, the parties whose names are subscribed in the first column of the schedule thereto being the registered holders of the 100 founders' shares of £1 each in the company of the second part, and Eustace James Anthony Balfour and Josiah Latimer Clark of the third part, be, and the same is hereby approved, and that the directors be and they are hereby authorised to carry the same into effect. That the capital of the company be increased to £300,000 by the creation of 20,000 new ordinary shares of £5 each, and that, notwithstanding the provisions of article 4 of the articles of association, 12,000 of such 20,000 new ordinary shares of £5 each be issued at par to the registered holders of the 100 founders' shares of £1 in the company as provided by the said agreement of the 16th day of December, 1897. That the directors be and they are hereby authorised to issue to any registered holder of a founders' share at any time hereafter not more than 120 new ordinary shares of £5 each at par upon such founders' shareholder transferring each founders' share of which he is the registered holder to Eustace James Anthony Balfour and Josiah Latimer Clark as trustees for the company, notwithstanding that the said agreement of the 16th day of December, 1897, may not have been executed by the holders of the whole of the said 100 founders' shares within the three months provided by clause 5 thereof."

The Direct United States Cable Company, Limited.

The report of the directors for the six months ended December 31st, 1897, to be presented at the forty-first ordinary general meeting of the company, to be held at Winchester House on Tuesday, January 25th, 1898, at 2 o'clock p.m., states that the usual statements of account for the half-year ended December 31st, 1897, are submitted herewith. The half-year's revenue, after deducting out-payments, amounted to £50,098 2s. 8d., as compared with £47,601 2s. 1d. for the corresponding period of 1896, showing a difference of £2,497 0s. 7d. in favour of the half-year under review. The working and other expenses for the same period, including income-tax, but exclusive of cost of renewal and repairs of cable, amounted to £19,722 13s. 10d, leaving a balance of £30,375 8s. 10d. as the net profit, making, with £3,927 13s. 4d. brought forward from the previous half-year, a total of £34,303 2s. 2d. For the corresponding period of 1896 the working expenses and other payments amounted to £19,815 13s. 6d. Interim dividends of 3s. per share for the quarter ended September 30th, 1897 (paid October 26th, 1897), and of 3s. per share for the quarter ended December 31st, 1897 (payable January 29th, 1898), together amounting to £18,213, have been declared, and after setting aside £12,000 to the reserve fund account, the balance of £4,090 2s. 2d. on the revenue account has been carried forward. The reserve fund account has been debited with £8,325 0s. 11d. for cost of cable and repairs, and with £2,000 written off the Ballinskelligs Buildings account, and after being credited with interest on investments, and sum transferred from revenue account, the balance of the reserve fund now amounts to £345,767 17s. 9d.

Blackpool and Fleetwood Tramroad Company.

An extraordinary meeting of the shareholders of this company was held last week in Association Chambers, Manchester, to authorise the promotion in Parliament of a Bill to give the company powers to construct tramways in Blackpool. Mr. George Richardson presided. It is proposed to construct a double line from Regent Terrace along the Carriage Drive, authorised by the Blackpool Improvement Act, 1893; a single line from Queen Square to the Carriage Drive, and a single line from Dickson Road to Queen Street. But it was explained to the meeting that it would not be necessary to construct these lines if the company obtained, as they hoped to do, running powers over the lines of the Blackpool Corporation. The company propose to take powers to raise £75,000 of additional capital. If it becomes necessary to issue new shares these will be offered at par to the present shareholders.

The Chairman, in moving the adoption of a resolution approving of the Bill, said the line to Fleetwood was being rapidly pushed forward, and would probably be open for traffic by May 1st.

The resolution was adopted.

The Eastern Telegraph Company.

The half-yearly meeting of this company was held at Winchester House yesterday. The Marquis of Tweedale presided, and referred to the increase in the revenue and the working expenses. The Cape traffic had fallen off, but that had been more than counterbalanced by an increase in the Indian traffic, due to the disturbances on the frontiers. After referring to the improvements made in the system from time to time, the report was adopted.

An extraordinary meeting was subsequently held for approving the conversion of the existing preference shares.

Stock Exchange Settlements.—Applications have been made to the Stock Exchange Committee (1) to appoint a special settling day in, and to grant a quotation to: Bournemouth and Poole Electricity Supply Company, Limited—6,000 4½ per cent. cumulative preference shares, and 6,000 ordinary shares; County of London and Brush Provincial and Electric Lighting Company, Limited—further issue of 10,000 ordinary shares; Direct West India Cable Company, Limited—12,000 shares; (2) to appoint a special settling day in Cape Electric Tramways, Limited—285,157 vendors' £1 shares, fully paid, Nos. 1 to 285,157; and (3) to allow the following securities to be quoted in the Official List: Barcelona Tramways Company, Limited—further issue of 5,072 ordinary shares, Nos. 14,929 to 20,000; Direct West India Cable Company, Limited—£120,000 4½ per cent. registered debentures; Halifax and Bermudas Cable Company, Limited—5,000 shares, Nos. 1 to 5,000, and £103,500 4½ per cent. first mortgage debentures. Also to appoint a special settling day in, and to grant a quotation to:—West Coast of America Telegraph Company, Limited—30,008 shares of £2 10s. each, and £150,000 4 per cent. debentures, in lieu of the shares and debentures of the old company of the same name now quoted; and to allow the following securities to be quoted in the Official List:—Commercial Cable Company—Further issue of £264,711 sterling 4 per cent. 500-year debenture stock.

City and South London Railway Company.—The accounts for the half-year ended December 31st show a balance, after providing for the debenture interest and the full dividend on the 5 per cent. preference shares, sufficient to allow the payment of a dividend on the consolidated ordinary stock at the rate of 1¾ per cent. per annum, carrying forward a balance of £1,511 to the new account. The dividend for the corresponding period last year was at the rate of 1¾ per cent. per annum, the balance carried forward being £1,314.

City of London Electric Lighting Company.—All outstanding forms of application (with the banker's receipt for the payment upon application which is attached thereto), and all certificates for fifths of a share of the issue of 10,000 ordinary shares, November, 1897 (Nos. 90,001 to 100,000), must be lodged with the company on or before 31st inst., otherwise the same will be liable to to cancellation or forfeiture at the discretion of the board.

The Eastern Extension, Australasia and China Telegraph Company, Limited.—This company notifies that the interest on the 4 per cent. mortgage debenture stock for the half-year ended 31st inst. will be paid by warrant on February 1st next. The stock register will be closed from the 27th to the 31st inst., both days inclusive.

Westminster Electric Supply Corporation.—During the past week this company has offered 3½ per cent. debentures to the extent of £200,000 for subscription. They were issued at par, redeemable in March, 1920, at par. We learn from the financial press that the issue was subscribed four times over.

The St. James' and Pall Mall Electric Light Company, Limited.—The Directors recommend a dividend for half-year ending December 31st of 11s. per share on the ordinary shares, making, with the interim dividend, 14½ per cent. for the year 1897.

Electric Construction Company.—The transfer books for the ordinary shares will be closed from 18th to 31st inst. inclusive, for the payment of the second half of the dividend of 6 per cent. per annum declared on July 22nd last.

The Globe Telegraph and Trust Company.—The directors announce an interim dividend of 1s. 9d. per share on the ordinary shares.

Oldham, Ashton and Hyde Electric Tramway.—The letters of allotment have been posted.

TRAFFIC RECEIPTS.

The City and South London Railway Company. The receipts for the week ending January 16th, 1898, were £1,085; week ending January 17th, 1897, £1,085; total receipts for half-year, 1898, £3,259; corresponding period, 1897, £3,278; decrease, £14.

The Liverpool Overhead Railway Company. The receipts for the week ending January 16th, 1898, amounted to £1,361; corresponding week last year, £1,278; increase, £83.

The Western and Brazilian Telegraph Company, Limited. The receipts for the week ending January 14th, 1898, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,240.

THE APPLICATION OF VECTOR ALGEBRA TO ALTERNATING CURRENTS.

By W. G. RHODES, M.Sc., Royal Technical Institute, Salford.

(*Concluded from page 56.*)

STATIONARY TRANSFORMER.

23. We will now apply the method to the study of a stationary transformer in which the reactances and mutual inductions may be considered constant.

Let the resistance of the primary circuit be r_1, its reactance s_1, and the primary current i_1, and let the corresponding quantities for the secondary circuit (internal and external), be r_2, s_2, and i_2, the mutual induction between the two circuits M; and the potential difference applied between the primary terminals, e.

Then, following the argument of Section 21, the vector equation of E.M.Fs. in the primary circuit is

$$r_1 i_1 + k s_1 i_1 + k p \text{M} i_2 = e. \qquad (28)$$

The E.M.F. in the secondary circuit due to mutual induction is $- k p \text{M} i_1$. This has to furnish a component, $r_2 i_2$, in phase with the secondary current to drive the current against the ohmic resistance of the circuit, and also a component, $k s_2 i_2$, to balance the E.M.F., $- k s_2 i_2$, due to the secondary reactance. We thus have the vector E.M.F. equation

$$r_2 i_2 + k s_2 i_2 = - k p \text{M} i_1,$$

or

$$r_2 i_2 + k s_2 i_2 + k p \text{M} i_1 = 0. \qquad (29)$$

Equations (28) and (29) are then the vector E.M.F. equations of the primary and secondary circuit respectively. Eliminating first i_2 and then i_1, we get

$$\{(r_1 r_2 - s_1 s_2 + p^2 \text{M}^2) + k (r_1 s_2 + r_2 s_1)\} i_1 = (r_2 + k s_2) e$$

and $$\{(r_1 r_2 - s_1 s_2 + p^2 \text{M}^2) + k (r_1 s_2 + r_2 s_1)\} i_2 = - k p \text{M} e$$

which may be written in the forms

$$[\{r_1 (r_2^2 + s_2^2) + p^2 r_2 \text{M}^2\} + k \{s_1 (r_2^2 + s_2^2) - p^2 s_2 \text{M}^2\}] i_1 = (r_2^2 + s_2^2) e \qquad (30)$$

and $$\{- (r_1 s_2 + r_2 s_1) + k (r_1 r_2 - s_1 s_2 + p^2 \text{M}^2)\} i_2 = p \text{M} e \qquad (31)$$

Hence the *magnitudes* of the primary and secondary currents are given by

$$\left.\begin{aligned} i_1 &= \frac{e}{\sqrt{\left\{ r_1^2 + s_1^2 + 2 p^2 \text{M}^2 \dfrac{(r_1 r_2 - s_1 s_2)}{r_2^2 + s_2^2} + \dfrac{p^4 \text{M}^4}{r_2^2 + s_2^2} \right\}}} \\ i_2 &= \frac{p \text{M} e}{\sqrt{\{(r_1^2 + s_1^2)(r_2^2 + s_2^2) + 2 p^2 \text{M}^2 (r_1 r_2 - s_1 s_2) + p^4 \text{M}^4\}}} \end{aligned}\right\} \qquad (32)$$

If R and S are the equivalent resistance and reactance of the primary circuit, we get at once from equation (30)

$$\left.\begin{aligned} \text{R} &= r_1 + \frac{p^2 r_2 \text{M}^2}{r_2^2 + s_2^2} \\ \text{and} \quad \text{S} &= s_1 - \frac{p^2 s_2 \text{M}^2}{r_2^2 + s_2^2} \end{aligned}\right\} \qquad (33)$$

From equation (30) we also see that the primary current lags behind the applied potential difference by an angle θ, where

$$\tan \theta = \frac{s_1 (r_2^2 + s_2^2) - p^2 s_2 \text{M}^2}{r_1 (r_2^2 + s_2^2) + p^2 r_2 \text{M}^2},$$

whence the current and applied potential difference are in phase if

$$s_1 s_2^2 - p^2 \text{M}^2 s_2 + s_1 r_2^2 = 0, \qquad (34)$$

that is, for a given primary reactance there are two values of the secondary reactance for which resonance may occur in the primary circuit, provided the roots of equation (34) are real, that is, if

$$p^2 \text{M}^2 > 2 s_1 r_2.$$

From equation (31) we see that the secondary current lags behind the primary potential difference by an angle $\pi - \phi$, where

$$\tan \phi = \frac{r_1 r_2 - s_1 s_2 + p^2 \text{M}^2}{r_1 s_2 + r_2 s_1}.$$

It is evident from this that the secondary current is in exact opposition to the primary applied potential difference if

$$r_1 r_2 - s_1 s_2 + p^2 \text{M}^2 = 0, \qquad (35)$$

and this condition is satisfied for one value only of s_2.

Moreover, conditions (34) and (35) cannot be satisfied simultaneously, since then we should also have

$$r_1 s_2 + r_2 s_1 = 0,$$

and the secondary current would be infinite, as is seen by reference to equation (31).

If condition (34) is satisfied we see from equation (30) that the primary current is given by

$$i_1 = \frac{e}{r_1 + \frac{s_1}{s_2} \cdot r_2} \qquad (36)$$

which shows that even if the primary current is in phase with the impressed potential difference, its value depends upon the resistance of the secondary circuit, and the ratio of the reactances of the two circuits, as well as upon the primary resistance.

Again, from equations (32) we have

$$\frac{i_1}{i_2} = \frac{\sqrt{r_2^2 + s_2^2}}{p\,M}.$$

If now the secondary resistance is negligible compared with its reactance, and if its reactance is due simply to its self-induction L_2, this becomes

$$\frac{i_1}{i_2} = \frac{L_2}{M}.$$

If, further, there is no leakage, so that $M^2 = L_1 L_2$, L_1 being the primary self-induction,

$$\frac{i_1}{i_2} = \sqrt{\frac{L_2}{L_1}}$$

$$= \frac{N_2}{N_1}$$

where N_1 and N_2 are the number of turns on the primary and secondary coils respectively.

24. As a last example we will consider the action of an induction motor.

The Induction Motor.*

A multiphase induction motor may be considered as a transformer with its secondary circuit free to rotate. The primary coils are wound round a stationary laminated iron framework, and are fed by two or more alternating currents differing in phase from each other, so as to produce a more or less uniform magnetic field rotating with a more or less uniform angular velocity. We shall here suppose that the magnetic field is uniform and that its angular velocity is uniform also.

The secondary circuit usually consists of a number of short-circuited conductors imbedded near the periphery of cylinder built up of thin circular discs of iron.

The stationary part of the motor is called the *stator*, and the rotating part the *rotor*. The currents in the stator produce a rotating magnetic field which induces currents in the rotor conductors, the effect being a tendency on the part of the rotor to follow the rotating field.

25. Suppose that each circuit in the stator consists of N_1 turns of wire, and each rotor circuit of N_2 turns, and let the resistance and reactance of each stator circuit be r_1 and s_1 respectively, and of each rotor circuit when at rest r_2 and s_2, and let the E.M.F. induced per turn in the stator coils be e.

If ω_1 and ω_2 are the angular velocities of the rotating field and rotor respectively, and the frequency of the current i_1 in a stator coil be n, then the frequency of the currents i_2 in the rotor coils will be

$$\frac{\omega_1 - \omega_2}{\omega_1} \cdot n$$

or, putting σ for $\frac{\omega_1 - \omega_2}{\omega_1}$,

the frequency of the rotor currents is $\sigma\, n$.

σ is frequently called the "slip."

(We will suppose that E.M.Fs. and currents have their root mean square values.)

It follows that the E.M.F. induced per turn in the rotor coils is $\sigma\, e$. The E.M.F. induced in each circuit of the rotor coils is therefore given by

$$E_2 = \sigma\, N_2\, e \qquad (37)$$

and the vector E.M.F. equation is

$$r_2\, i_2 + k\, \sigma\, s_2\, i_2 = \sigma\, N_2\, e$$

the reactance when in motion being $\sigma\, s_2$. Thus

$$i_2 = \frac{\sigma\, N_2\, e}{r_2 + k\, \sigma\, s_2}$$

$$= \frac{\sigma\, N_2\, e\,(r_2 - k\, \sigma\, s_2)}{r_2^2 + \sigma^2\, s_2^2} \qquad (38)$$

The power spent per circuit in heating the rotor is then the scalar product of (37) and (38), that is

$$\text{power wasted} = \frac{\sigma^2\, N_2^2\, e^2\, r_2}{r_2^2 + \sigma^2\, s_2^2} \qquad (39)$$

26. Again, the E.M.F. induced in each stator circuit due to the rotating field is given by

$$E_1 = N_1\, e. \qquad (40)$$

Also, the current i_1 in the stator consists of two parts, the function of one part, i_1', being to excite the stator and produce the rotating field, and that of the other part i_1'' to transmit energy to the rotor.

But $$i_1'' = -\frac{N_2}{N_1}\, i_2$$

$$= -\frac{\sigma\, N_2^2\, e\,(r_2 - k\, \sigma\, s_2)}{N_1\,(r_2^2 + \sigma^2\, s_2^2)} \;\ldots \text{(by equation (38))} \qquad (41)$$

The power transmitted per circuit to the rotor is, therefore, the scalar product of the vectors

$$-N_1\, e \text{ and } -\frac{\sigma\, N_2^2\, e\,(r_2 - k\, \sigma\, s_2)}{N_1\,(r_2^2 + \sigma^2\, s_2^2)},$$

that is,

$$\text{Power transmitted to rotor} = \frac{\sigma\, N_2^2\, e^2\, r_2}{r_2^2 + \sigma^2\, s_2^2}. \qquad (42)$$

The output, P, of the motor is then obtained by subtracting (39 from (42), that is

$$P = \frac{\sigma\, N_2^2\, e^2\, r_2}{r_2^2 + \sigma^2\, s_2^2} - \frac{\sigma^2\, N_2^2\, e^2 r_2}{r_2^2 + \sigma^2\, s_2^2}$$

$$= \frac{N_2^2\, e^2\, r_2\, \sigma\,(1 - \sigma)}{r_2^2 + \sigma^2\, s_2^2} \qquad (43)$$

27. To find the torque T exerted per circuit on the rotor, we must divide the output P by the angular velocity ω_2, but

$$\sigma = \frac{\omega_1 - \omega_2}{\omega_1},$$

therefore $$\omega_2 = \omega_1\,(1 - \sigma)$$

that is $$T = \frac{N_2^2\, e^2\, r^2\, \sigma}{\omega_1\,(r_2^2 + \sigma^2\, s_2^2)}. \qquad (44)$$

This expression gives the torque in terms of the slip, the resistance and reactance of the rotor coils, the E.M.F. developed per turn by the rotating field at full frequency, the number of turns per section on the rotor, and the angular velocity of the rotating field.

The relation between torque and slip is shown graphically in fig. 11.

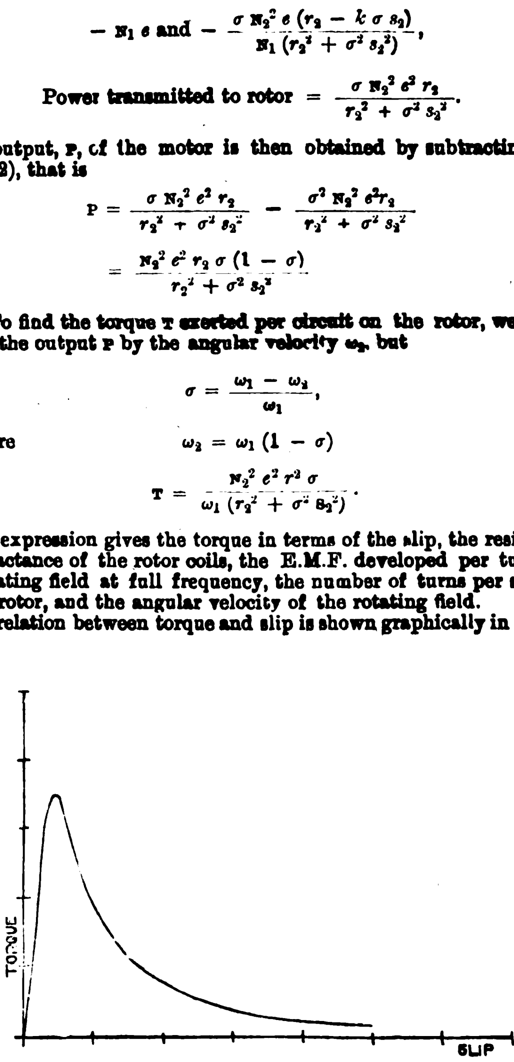

Fig. 11.

Equation (44) shows the starting torque is (putting $\sigma = 1$)

$$T_0 = \frac{N_2^2\, e^2\, r_2}{\omega_1\,(r_2^2 + s_2^2)},$$

which is greater the less the reactance of the rotor bars, and the less the angular velocity of the rotating field.

To give a large torque the E.M.F. induced per turn by the rotating field should be large, that is, the air-gap should be as small as possible and leakage should as far as possible be avoided.

The Monophase Induction Motor.

28. In the foregoing theory it has been assumed that the rotor bars are cut by a magnetic field rotating at a uniform velocity ω_1. So long that this condition is satisfied the number of independent currents in the stator does not affect the theoretical treatment of the problem. When, however, the stator is fed by one alternating current only, the conditions of the problem are altered. The resultant alternating field now preserves a constant direction relative to the stator. We can, however, regard this resultant field as compounded of two uniform magnetic fields rotating with equal angular velocities but in opposite directions round the stator.

29. Suppose, now, that the rotor is started in either direction by any means whatever and let the "slips" relative to the two rotating fields be σ_1 and σ_2 respectively, so that $\sigma_1 + \sigma_2 = 2$, and $\sigma_1\, \sigma_2 < 1$ (except at start when it equals unity).

If the rotor is started in the direction such that $\sigma_1 < 1$, it will, by (44) be subject to a torque

$$T_1 = \frac{N_2^2\, e^2\, r_2\, \sigma_1}{\omega_1\,(r_2^2 + \sigma_1^2\, s_2^2)}$$

tending to diminish σ_1, and a torque

$$T_2 = \frac{N_2^2\, e^2\, r_2\, \sigma_2}{\omega_1\,(r_2^2 + \sigma_2^2\, s_2^2)}$$

* See also "Theory of the General Alternating Current Transformer," by C. P. Steinmetz, *Transactions* American Institute Electrical Engineers, 12, pp. 351—365, 1897, and "Alternating Current Motors," by W. G. Rhodes, M.Sc., Electrical Review, Vol. 37, pp. 599-600, 1895, and Vol. 38, pp. 139—142, 1896.

tending to increase σ_1 and diminish σ_2. The resultant torque in the direction of σ_1 diminishing is

$$
\begin{aligned}
T_1 - T_2 &= \frac{N_2^2 e^2 r^2}{\omega_1} \left\{ \frac{\sigma_1}{r_2^2 + \sigma_1^2 s_2^2} - \frac{\sigma_2}{r_2^2 + \sigma_2^2 s_2^2} \right\} \\
&= \frac{N_2^2 e^2 r_2}{\omega_1} \; \frac{(\sigma_2 - \sigma_1)\,(\sigma_1 \sigma_2 s_2^2 - r_2^2)}{(r_2^2 + \sigma_1^2 s_2^2)\,(r_2^2 + \sigma_2^2 s_2^2)}. \qquad (45)
\end{aligned}
$$

30. Equations (44) and (45) bring out clearly the difference between the actions of multiphase and monophase induction motors. A multiphase motor will run up to synchronism with the rotating field before the torque vanishes, and its value is a maximum for variations of σ when $r_2^2 - \sigma^2 s_2^2 = 0$. In a monophase motor, however, the torque is zero when $\sigma_2 = \sigma_1$ (at start), and again when

$$\sigma_1 \sigma_2 s_2^2 - r_2^2 = 0,$$

that is, when

$$\sigma_1 \sigma_2 = \left(\frac{r_2}{s_2}\right)^2,$$

or

$$\sqrt{\sigma_1 \sigma_2} = \frac{r_2}{s_2} \qquad (46)$$

which shows that every monophase induction motor has, for a given frequency of the current, a speed peculiar to itself beyond which it cannot go, and this speed is determined by the ratio of the resistance to the reactance of the rotor windings.

Equation (45) also shows that unless s_2 is greater than r_2, the motor will not run at all, because the product $\sigma_1 \sigma_2$ being necessarily less than unity in whichever direction the motor is started, there would be a torque in the opposite direction.

31. Whereas, then, the multiphase motor can possibly approach to synchronous running with the rotating magnetic field, if the load were made sufficiently small, a monophase induction can never go beyond the limit set (see (46)) by its own resistance and reactance, and will thus, under the most favourable conditions, have a speed less than that corresponding to synchronism with the supply current.

32. With regard to the representation of root mean square (R M S) values by vectors, and interpreting results deduced from vector equations as if the quantities represented R M S values, we can only say that it is often convenient to take R M S instead of maximum values, more especially since for most purposes we can take any periodic E.M.F. or current curve and proceed to make calculations as if the actual curve was replaced by a simple harmonic curve having the same periodic time and the same R M S value, and if we give to a vector a magnitude to represent the R M S value, and a suitable phase positions, we shall accurately interpret any results involving only *scalar products*.

33. The simplicity of vector calculations in alternating current problems and the ease with which the method may be taught to students whose mathematical knowledge is of an elementary nature renders the teaching of a difficult subject much less laborious; and we think that the sooner young electricians know that much may be learnt of the theory of alternating currents without a previous arduous mathematical training, the sooner will a greater interest be aroused in what is perhaps the most fascinating branch of physical science.

34. In conclusion I may add that the foregoing theory, most of which is not elsewhere obtainable, may be understood by any reader possessing only a knowledge of a little trigonometry and of algebra up to quadratic equations, on taking for granted Propositions 1, 2, and 3 of Section 9. These, together with Sections 6 and 7, are the keynotes of the whole method which I have applied to a few of the more prominent problems of alternating currents. When these are thoroughly understood, it should be an easy matter to adapt the method to most problems which may arise.

Corrigendum.

I regret that there is an algebraical error in Section 22 (second article). As the slip affects the final result I have completely rewritten that section. My thanks are due to Mr. Alexander Russell, M.A., for very kindly drawing my attention to the error in a private letter.

22. In this case the vector equations to be solved are

$$
\left.\begin{aligned}
(r_1 + k s_1)\, i_1 + k p M_{12}\, i_2 &= e \\
k p M_{21}\, i_1 + (r_2 + k s_2)\, i_2 &= e \\
\text{and} \qquad i &= i_1 + i_2
\end{aligned}\right\} \qquad (23)
$$

whence, on putting $M_{12} = M_{21} = M$

$$
\left.\begin{aligned}
\{r_1 r_2 - s_1 s_2 + p^2 M^2 + k (r_1 s_2 + r_2 s_1)\}\, i_1 &= \{r_2 + k (s_2 - p M)\}\, e \\
\{r_1 r_2 - s_1 s_2 + p^2 M^2 + k (r_1 s_2 + r_2 s_1)\}\, i_2 &= \{r_1 + k (s_1 - p M)\}\, e
\end{aligned}\right\}
$$

Putting for shortness

$$
\left.\begin{aligned}
r_1 r_2 - s_1 s_2 + p^2 M^2 &= P \\
\text{and} \qquad r_1 s_2 + r_2 s_1 &= Q
\end{aligned}\right\}
$$

these equations become

$$
\left.\begin{aligned}
(P + k Q)\, i_1 &= \{r_2 + k (s_2 - p M)\}\, e \\
(P + k Q)\, i_2 &= \{r_1 + k (s_1 - p M)\}\, e
\end{aligned}\right\} \qquad (23a)
$$

which by multiplying both sides of the equations by $P - k Q$, and simplifying, may be written

$$
\left.\begin{aligned}
(P^2 + Q^2)\, i_1 &= [P r_2 + Q (s_2 - p M) + k \{P (s_2 - p M) - r_2 Q\}]\, e \\
(P^2 + Q^2)\, i_2 &= [P r_1 + Q (s_1 - p M) + k \{P (s_1 - p M) - r_1 Q\}]\, e
\end{aligned}\right\} (24)
$$

These are the vector current equations giving the components of i_1 and i_2 along and at right angles to e. By addition we have

$$
\left.\begin{aligned}
&(P^2 + Q^2)\, i = \\
&\quad [P (r_1 + r_2) + Q (s_1 + s_2 - 2 p M) + k \{P (s_1 + s_2 - 2 p M) - Q (r_1 + r_2)\}]\, e
\end{aligned}\right\} (25)
$$

which gives the components of the main current along and at right angles to e; thus the component in phase with e is

$$\frac{P (r_1 + r_2) + Q (s_1 + s_2 - 2 p M)}{P^2 + Q^2} \cdot e,$$

and the component at right angles to e, or the wattless component, as it is called, is

$$\frac{P (s_1 + s_2 - 2 p M) - Q (r_1 + r_2)}{P^2 + Q^2} \cdot e.$$

Multiplying and dividing the right-hand side of equation (25) by

$$P (r_1 + r_2) + Q (s_1 + s_2 - 2 p M) - k \{P (s_1 + s_2 - 2 p M) - Q (r_1 + r_2)\},$$

we get, after some reductions,

$$i = \frac{\{(r_1 + r_2)^2 + (s_1 + s_2 - 2 p M)^2\}\, e}{P (r_1 + r_2) + Q (s_1 + s_2 - 2 p M) - k \{P (s_1 + s_2 - 2 p M) - Q (r_1 + r_2)\}},$$

which shows that the equivalent resistance, R, and reactance, S, of the parallel circuit are given by

$$
\left.\begin{aligned}
R &= \frac{P (r_1 + r_2) + Q (s_1 + s_2 - 2 p M)}{(r_1 + r_2)^2 + (s_1 + s_2 - 2 p M)^2} \\
- S &= \frac{P (s_1 + s_2 - 2 p M) - Q (r_1 + r_2)}{(r_1 + r_2)^2 + (s_1 + s_2 - 2 p M)^2}
\end{aligned}\right\} \qquad (26)
$$

and the equivalent impedance, I, is given by

$$
\begin{aligned}
I^2 &= R^2 + S^2 \\
&= \frac{P^2 + Q^2}{(r_1 + r_2)^2 + (s_1 + s_2 - 2 p M)^2},
\end{aligned}
$$

or, putting in the values of P and Q,

$$
\left.\begin{aligned}
R &= \frac{(r_1 + r_2)(r_1 r_2 - s_1 s_2 + p^2 M^2) + (s_1 + s_2 - 2 p M)(r_1 s_2 + r_2 s_1)}{(r_1 + r_2)^2 + (s_1 + s_2 - 2 p M)^2} \\
- S &= \frac{(s_1 + s_2 - 2 p M)(r_1 r_2 - s_1 s_2 + p^2 M^2) - (r_1 + r_2)(r_1 s_2 + r_2 s_1)}{(r_1 + r_2)^2 + (s_1 + s_2 - 2 p M)^2} \\
I^2 &= \frac{(r_1 r_2 - s_1 s_2 + p^2 M^2)^2 + (r_1 s_2 + r_2 s_1)^2}{(r_1 + r_2)^2 + (s_1 + s_2 - 2 p M)^2}.
\end{aligned}\right\} (27)
$$

AMBROIN.

[COMMUNICATED.]

Among the various insulating materials which, besides ebonite, vulcasbest, porcelain, and slate, have from time to time made their appearance, ambroin is well worth consideration by electrical engineers, and during the short period of its existence the many advantages it presents to the electrical industry, have caused it to be highly appreciated by all who, from practical experience, are in a position to judge.

Ambroin is composed of fossil copal and silicates, and the silicates are saturated and mixed with the copal by a patent process in such a manner that, after being subjected to a very great pressure, an exceedingly strong, firm, uniform, and non-hygroscopic material is produced. By varying the proportions of the component parts a number of qualities, to meet all possible requirements that can be demanded of an insulator, are manufactured, and, for example, the fireproof quality contains only a sufficient quantity of copal to ensure the adhesion of the mass and to destroy the water-absorbing capacity of the silicates.

A short summary of the qualities of ambroin may be of interest.

After being subjected to pressure ambroin does not undergo any variation in volume, and, in consequence, the most complicated pieces can be very accurately moulded. This is of special importance where the insulation consists of several parts, as all the parts are interchangeable, and portions which are particularly subjected to wear can be easily replaced. Screws can be moulded in ambroin and do not require any further cutting to ensure accuracy.

Ambroin, even in the open air, does not absorb moisture, in which it differs from most other materials, and this not only greatly increases its value as an insulator, but there is no danger of the destruction of the insulation owing to the water taken up freezing in the winter. To illustrate the relative amount of water absorbed by various materials we give the following comparison. Pieces of equal size and with a smooth surface were taken, and after being immersed in water at 75° C. for $1\frac{1}{2}$ hours the increase in weight was:—

1. Ambroin	0 32 per cent.
2. "Aetna" material (the surface became rough)	3 17 „
3. Stabilit	1·41 „
4. Vulcasbest	4·80 „
5. Vulcanised fibre	24 5 „

Dielectric strength according to tests of the Reichsanstalt, Berlin:—

(1) A dry sheet 0·34 mm. thick was *not* pierced with 5,000 volts.

(2) A sheet 5 mm. thick, after lying in a room containing 40 per cent. moisture, was *not* pierced with 36,000 volts.

The *insulation resistance* of dishes 3 mm. thick with 200 volts:—

(1) Without preparation was 200,000 megohms.

(2) The dish was half filled with sulphuric acid, 26° Bé, covered up and subjected to a temperature of 49° C. for 10 days. After a superficial drying with blotting paper the resistance was the day following 150,000 megohms, and two days later 200,000 megohms.

In view of the great importance of mechanical strength in an insulating material, especially when used for traction work, a comparison between ambroin and other substances should prove instructive. For the purpose of the compression tests 1-in. cubes of ambroin and ebonite were taken, which presented a surface of 1 sq. in. to the pressure.

At normal temperature the destruction of the ambroin cube took place under a load of 2,688 lbs., and of the ebonite cube under a load of 3,196 lbs.

At 60° C. the ambroin cube withstood the pressure up to 1,958 lbs., while the destruction of the ebonite cube begins under a very small load.

To test the *tensile strength*, rods of equal dimensions were taken, and at normal temperature the breaking strain was:—

For ebonite...	1,088 lbs. per sq. in.
" aetna material	1,350 " "
" ambroin	2,082 " "

At 60° C. ebonite stretched extensively, while the tensile strength of ambroin is even greater than at ordinary temperature.

The ordinary quality of ambroin does not begin to burn until subjected to a temperature of 400° C., while the special quality, made for switchboards, &c., withstands the hottest zone of a bunsen flame (1,700° C.) for some considerable time, and this quality can, therefore, be used in all cases where, owing to short circuits, sparking causes a momentary great heat. Of other materials, ebonite and celluloid soften in water at a temperature of 70° C., celluloid burns readily at 110° C., ebonite at 180° C. and stabilit cracks when subjected to heat.

Ambroin, quality S, withstands the action of sulphuric acid, 45° Bé., up to a temperature of 80° C. and of concentrated hydrochloric acid, and this quality is well adapted for battery boxes, while a special quality which is not attacked by alkalio or chlorine is made for electro-chemical purposes.

Ambroin does not contain sulphur or any other oxidising substances.

The uses to which ambroin may be put include the insulating parts of dynamos, electromotors, and transformers, as Brush insulators, commutator rings, transformer bobbins, &c., also accumulator boxes, while plates for resistances and switchboards, either with contact studs complete or with holes moulded in to screw down the contact pieces, deserve special attention. Ambroin overhead insulators for tramways have been used on many of the principal lines on the Continent with satisfactory results, and it is particularly adapted for motor cars, in fuse boxes, spark arresters, switchboards, switches and controller insulation. For the last named a special quality is made, which combines high insulation with resistance against the action of sparking, and which is evenly and firmly pressed on to the controller axle.

REPAIRING A "BURNT-OUT" COMMUTATOR.*

By NORMAN H. CROWELL.

If the dynamo-tender understands his business and has suitable instruments at hand, it may be but a matter of a few minutes' time to discover the cause of a "breakdown" and set about its repair. If, however, he happens to be a good steam engineer, but a novice at the practice of the electrical art, and tends dynamo by "throwin' her in gear" and trusting to luck, he may as well sit calmly down and wait for reinforcements.

Under the supervision of a competent electrician, a serious breakdown is of rare occurrence. There can be little trouble with the machine with a firm foundation, steady power, tight screws, evenly ground brushes, and the constant application of a good big "rag" to the parts where dirt, grease and copper dust collect.

In the case in hand the dynamo had gone on for months grinding out its existence with no attention from the tender. He never knew whether the brushes bobbed, the commutator cut or sparked, or where to oil the journals. This state of things could not continue long without something giving way, and the lights suddenly winked out one night leaving Mr. Engineer "up a stump."

By the aid of a dim and flickery lantern we hastily inspected the dynamo, field-magnet, wall attachments, ground wire and even the friction clutch. As far as could be seen everything was tight and in order. Now we must roll up our sleeves and hunt for the "trouble." A small boy eagerly grasps the opportunity to turn the "magneter" handle while we poke around feeling for shocks, and we find a good many.

Everything is found all right until we test the exciter, and here we find a grave condition of things. By placing one wire against a segment of the commutator and the other firmly against the end of the armature shaft, we get a merry tinkle from the bells. By testing the segments one by one we discover that about every third one is in connection with the shaft. We have located the difficulty, and now proceed with the treatment.

We first remove the armature from its chamber, and by testing it again we prove our theory to be the right one. Then we make out a little list of articles needed and send the small boy away with it. The list reads as follows: Twenty pieces of heavy mica, 4 × 5 ins.; can of shellac and brush; strip of heavy duck cloth, 6 ins. wide; needle and saddler's thread.

While he is in quest of these things, we place the armature in the lathe to facilitate matters, and unscrew the burr that holds the cap over the ends of the commutator segments. Next, we remove the "cap," and the cause of the short-circuit is visible to the eye. In several spots the thick mica layers are charred through, and when we peel them off we find the copper has a "worm-eaten" appearance.

Take a flat file and cut through the band of wires about the armature head. If the cover is badly worn or torn, file both bands and take the cover off entirely, saving the eyes for use on the new cover. This exposes to view the 20 pairs of wires leading from the armature to the lugs of the segments. Now comes the delicate task of spreading the segments. It is delicate for the reason that they are worn to the thinness of an ordinary pasteboard and require careful handling. However, by pulling gently with the pincers they are lifted from their bed and the charred insulation is scraped and blown away.

At this point, we test the connections between the armature wires and the lugs and find them good. Now carefully inspect the insulation of the base-cap, and if you find it unimpaired, proceed to the laborious task of cutting the mica into strips.

These strips we make ½ inch wide, 4 inches long, and cut one end off at an angle of 45°. Care must be taken to keep the mica from flaking, otherwise you will be greatly hindered in the work to follow. After enough strips are cut, we lay them in a place convenient to our reach and turn our attention to the dismantled commutator. Make sure that no small pieces of insulation adhere to the segments, and then carefully return them to their original position. Slip a heavy rubber band over their base to keep them in their place.

Now we insert the shaft in a vice, with the commutator end uppermost, giving us the most convenient position for handling the ticklish job we now undertake. The next step is to put a strip of the mica between each segment and its fellow, making sure that the pointed end fits the V-shaped recess in the base-cap closely. Take a strip and swab it with shellac, then gently pry two segments apart and slip in the strip. The job increases in difficulty as it nears completion.

A small wooden mallet may be used to tap the strips down into place, and this is the place to exercise patience as long as possible.

Now, with the task half done, the mica strips stick out ¼ in. from the normal surface of the commutator, and should project at least an inch beyond the ends of the segments. The ends that thus project are now carefully clipped off close to the segments with a pair of sharp shears, care being taken to make good clean cuts. When this is done, drop the mica ring behind the strips to hold them from the shaft. Now take an extra thick and fine sheet of mica, and cut out a circular piece with a hole in the centre. This is to take the place of the old insulation on the "cap," and must fit accurately, and be thick and solid.

Fit this ring to the cap and put the cap on the shaft in position. Now start on the burr. Unless you have access to a special vice for holding the cap firm, it will be very liable to turn, thereby twisting the segments out of position and perhaps destroying the insulation. This must be avoided, but the burr must be set on so tightly that there will be no probability of its loosening, although the direction of the armature's rotation may tend to unscrew it, which is unfortunately the case with many machines.

* *American Electrician.*

With the cap and burr in place, we proceed to remove the superfluous mica that confronts us. This is done best with a very sharp knife point. When the most of it has been cut and pared away with the knife, take the file and finish it.

Now, if you have succeeded in getting the commutator round or approximately so, you may be assured that your job has been well done, but if it presents an oval shape or a very uneven surface, you will probably have the pleasure of going over the whole process again. If it is oval the brushes will bob and dance until the bulging part wears thin and caves in. If uneven, the chances are that it will not permit lathing, and you may have to loosen the burr and spend an hour adjusting it. The commutator should be so nearly circular that a small amount of light filing will complete it.

Having removed the rubber band, you are ready to put on the drum or canvas coating on the armature head. It is a good idea to have some one who is handy with tools attend to the making of a duplicate of the old cover, which is a simple matter, while you are engaged on the other work. Wrap the cover tightly around the head and sew with the saddler's thread. Put on a liberal coat of shellac. Then cut some long strips of medium thin mica to support the band wires. Next wrap some No. 16 (B. & S.) wire around the edge of the drum over the strips of mica at a strong tension. Make a band about ½-in. wide and solder in several places. Care must be taken that no part of the cover or solder bulges out so that it will touch the chamber when the armature is placed in position.

Now everything is completed, and you are ready to slip the armature back into its chamber, adjust the brushes and start up. It will take a minute for the magnet to pick up, but if you have been thorough in your work you will have the satisfaction of seeing the pointer begin to dance, and when you turn the handle, realise that you have saved your company time as well as expense.

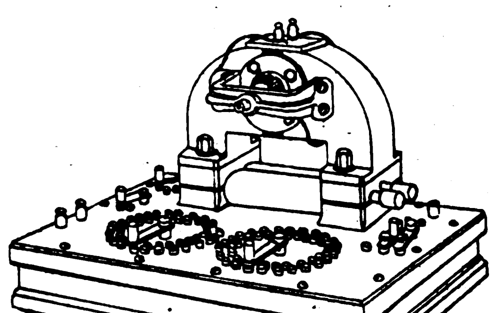
A MAGNETIC TESTING INSTRUMENT.

Messrs. R. B. Treat and S. W. Esterline, of Purdue University, Lafayette, Ind., have recently published a description of a piece of apparatus for testing samples of iron, which presents some features of interest, though no new principle of construction is involved. The general arrangement of the apparatus is shown in the figure. Two bars under comparison are clamped side by side, in holes turned to fit them, in heavy blocks of very soft iron. Round the bars are ebonite bobbins or spools, wound with copper wire, and a closely fitted slot-wound dynamo armature is run at a high known speed, presumably by a motor, in a gap between the blocks. The dynamo brushes are connected to a Weston voltmeter, so that only a very small current is taken from the armature, and the readings of the voltmeter are directly proportional to the flux through the armature.

The instrument can be used in two ways. In one the magnetising currents in the bobbins on the two bars may be adjusted, so that the fluxes in the two bars are equal, and opposite in direction. When this is the case, there will be no flux through the revolving armature, and the voltmeter will show no difference of potential between the brushes. If one bar, whose magnetic properties are previously ascertained, be used as a standard of reference, and the magnetising force of the current round it carried through any range, then by continually adjusting the magnetising force acting on the other bar, so as to give no deflection on the voltmeter, a continuous comparison between the properties of the two bars is obtained.

Another way of using the instrument is to remove one bar, and use the revolving armature and voltmeter to measure the flux through the iron circuit, as the magnetising force on the bar is continuously varied. By these means the hysteresis cycle of the specimen, or its B.H. curve, can be determined.

The dimensions of the test bars are 10 inches long, 4 π cm. between the yokes, and ·575 inch in diameter. The bobbins on the test bars are wound with 100 turns of wire, capable of carrying 10 amperes, giving a possible magnetising power of 1,000 ampere-turns. The two coils are connected in series, and switches are arranged by which the number of active turns on the two bobbins can be varied. In any case the ratio between the number of ampere-turns on the two bars is equal to the number of active turns. The number of turns on the bobbin round the bar which is intended to be used as a standard of reference, may be either 50, 75, or 100, while the number on the other bar may be anything from 1 to 100. The two switches seen in front of the magnetic parts change the number of turns on one magnetising coil, and are arranged to insert an equivalent resistance as each turn is cut out, so as to keep the resistance of the circuit unaltered. The armature has 7,000 turns, laid in 40 slots, and is driven at 4,000 revolutions per minute. With a flux density of 17,000 lines per square cm. through one bar, an E.M.F. of 90 volts is said to be generated, but this figure



seems to be inconsistent with the other data. The existence of one line of magnetic flux across the armature is said to be readily detected. The reluctance of the air-gaps at the dynamo armature is small, owing to the close fitting, and the areas of the clamped joints are 32 times the section of the bar.

An instrument of this kind, in which the magnetic flux through a bar can be continuously varied and measured on a direct reading instrument, offers great convenience in comparison with the method of obtaining the flux as the sum of a number of small increments measured separately by the throws of a ballistic galvanometer. The design is however, open to obvious objections. For instance, the method of changing the magnetic force in the bar by cutting out turns may be objected to on the ground that the distribution of force is varied as well as its total intensity, a defect that would not occur if the current were reduced or increased. Again, the behaviour of a bar kept in a state of tremor by the vibration of an armature would be different from its behaviour when unshaken. But for the use of engineers such objections are readily overbalanced by considerations of convenience, and we have no doubt from its description that the apparatus might be exceedingly valuable. A good deal of information about the arrangements for clamping the test bars, and other points of detail, is given in an article in the *Electrical World* of New York, December 11th, 1897, to which we may refer our readers.

THE TELEGRAPH TROUBLES.

The Clerks' Point of View.

By CHAS. H. GARLAND.

The case of the telegraph clerks has suffered in the past, because of the difficulties besetting a clear statement of their position. Documents have been prepared which have been summarised by the newspapers of the country, and garbled in the summary. Members of Parliament, unacquainted with the technicalities of Government employment, have attempted, with the most laudable intentions, to explain the complaints to the House of Commons. The result has been a misunderstanding. Public functionaries and trade-union officials have always failed to grasp the peculiar *milieu* of a civil servant and his limitations; and the class papers are read only by the class affected. Again, considerable public attention is attracted only during periods of great excitement, and newspapers, eager for exclusive news of a sensational character, have over-emphasised or mis-stated minor points, to the utter exclusion of the more important issues. The association of last year's movement, with a strike against the performance of overtime, reasonable or unreasonable, is an instance of how far misconception and misrepresentation can go. The main point in dispute was the violation of certain rights in the matter of promotion. I therefore welcome the opportunity afforded me by the editors of the ELECTRICAL REVIEW to summarise our point of view on the principal claims of the postal telegraph clerks.

There are certain general principles underlying the whole of our movement which are, from time to time, attacked by the representatives of the Department, and the organs that range themselves on their side. As agreement with these principles is the necessary presupposition of any sympathy with our claims, it would perhaps be well to deal with them before attacking these details. A criticism of our opponents will make our position clear.

It is seriously contended that, provided the salary and prospects remain the same as they were some 16 years ago, the staff should be content there being no ground for complaint. It will be my aim to prove that in the case of a large section of postal employés the prospects have actually deteriorated during the past 16 years, but meanwhile I will draw attention to this principle of departmental economy, and offer a few reasons against it. It is neatly stated in a letter from Sir S. Walpole to a Mr. Newton, dated August 31st, 1897: "The prospect of obtaining £190 a year to which reference was made in the Civil Service Commissioners' Circular issued between 1880 and 1891 . . . . still remains, and as the proportion of superior appointments, including senior telegraphists, in the number, to the total number of the staff is almost exactly the same as it was at the date of Mr. Fawcett's revision (1881) whatever prospect a young man had at that time of obtaining promotion to the higher classes he enjoys now." This argument may be called the justification of standing still, and is entirely opposed to any desire for progress. The other general objections to our movement have been stated in various quarters, notably by Mr. Lewin Hill (assistant secretary G.P.C.) in his evidence before the Tweedmouth Committee on March 23rd, 1896. The same views have been crudely summarised by the *Times* so recently as December 29th, 1897, and are tersely expressed in all their native ugliness in the following sentences from a leader of that date:—"It may be suggested to them (the telegraph clerks) that they still possess the right to resign positions which do not suit them. The Government has no difficulty whatever in finding plenty of candidates for vacancies, and so long as that is the case it has no occasion to raise its terms. It is not difficult to become a telegraph clerk of average utility, and there are any number of people quite ready to accept the present conditions of service." These arguments may be described as the right to resign, which, in the case of old clerks, is also the right to starve, and the right of the State to "sweat."

Let us look, first, at the justification for standing still. The Government should be, "in the first flight of employers," a Cabinet Minister said in the House of Commons. Mr. Arnold Morley, when Postmaster-General, declared that the State should be "the model employer." If the Government is to set the example to other employers, should it stand still in the midst of a general progression? Yet this is what it has done, if it has left the pay and prospects of its employés identically the same as in 1881. Take a rapid glance at two recently published reports of the labour department of the Board of Trade. The report of Mr. Burnett, the chief labour correspondent, upon the strikes and lock-outs of 1896, shows that for several years there has been a notable upward tendency of wages. The Fourth Annual Report of the Board of Trade (1896-7) shows conclusively that while the hours of work are on the decrease, there is a distinct increase in the wages paid. A few figures from the latter document will clearly illustrate this. Taking the class described as "Employés of public authorities" as illustrating the general tendency, and approximating somewhat in terms of service to the civil servant, we find that the "average amount of decrease in weekly hours of labour (per head of those affected") is stated as follows:—

1893.	1894.	1895.	1896.
4·49	4·02	5·32	2·65

During the same period, the "net effect of changes on weekly wages [(+) = increase (−) = decrease]" is given for the same class in the following figures:—

Amount per head of those affected:

1893.	1894.	1895.	1896.
+ 1·6¾	+ 1·5¾	+ 1·7½	+ 1·2¼

We will suppose that the pay and prospect offered after the revision of 1881 were based upon some consideration of the market value of the work at that period, and we will bear in mind that the market value of the work is affected by the standard of living of the class performing the work. This standard of living may be raised, and it is a commonplace of economics that the luxuries of one generation become the necessaries of another. Again, the cost of maintaining an equal standard of living may be increased by a rise in price of the necessaries of life. The latter eventuality has undoubtedly happened in London. The cost of living has increased. To take only one important factor. The average rise of London rent (on unaltered buildings) since 1870 has been £304,634 per annum, or 1·08 per cent. on the average valuation. The homes of Londoners have been driven farther and farther from the centre by the increase in the commercial importance of the City; the hours have been lengthened by the railway journey, and the cost of living has been increased by the daily railway fare. To take only this one instance of the increase in cost, without discussing the large increase in the cost of meat and other things, we see that even if the standard of living had remained the same as in 1881, the relative value of the pay and prospects offered to telegraph clerks has decreased. Meanwhile, however, it has been the constant endeavour of public organisations to raise the standard of living of all classes by the multiplication of educational and other facilities. Undoubtedly these efforts have been crowned with some measure of success. Leaving aside the question of whether the pay and prospects of telegraph clerks have retrograded, it is obvious that for a Government to plume itself on being a model employer because it has stood still during 16 years of progress is a sheer absurdity. If telegraph clerks ask that better pay and prospects should now be given than were offered in 1881 they are merely pressing the Government to move with the times and take its proper place among "the first flight of employers."

The "right to resign" is offered to those who, under pressure of changing environment, feel that the conditions of service are not what they should be. By the time a boy has become a good telegraph clerk, despite the *Times*, he has spent a sufficient period in the service to be too old for commencing in another profession. His whole training has been directed to fitting him for the keen competitive examination which he has to pass, and has consequently unfitted him for any other employment. At 16 years he enters the Post Office full of hope, but with all the irresponsibility of youth. He is little troubled with prospects. He fondly thinks they are assured. Youth is essentially unreflective, and it is not till he has passed some four or five years in postal service, and has left the parental nest, that he begins to realise his cruel disillusionment. Then he is offered the right to resign; and then he feels he cannot accept it. On the principle that half a loaf is better than none, he hangs on, and by means of overtime and careful management, perhaps succeeds in getting through the years that divide him from a salary he can live on. With only the prospect of throwing himself on an overcrowded labour market, having spent the best years of his life in acquiring a trade of which the Post Office has a monopoly, he feels he cannot use the "right to resign," which is so freely offered to him. So there are relatively few resignations. But he has another right. He has the right possessed by all citizens to look to the Government not to exploit his weakness, and to call upon the State to become, in reality, the "model employer." Where any prospect of placing his special knowledge is opened up, the Government employé is quick to take advantage of it. The *Cables Recorder*, a Valparaiso paper, of May, 1895, said, speaking of the staff of the Commercial Cable Company:—"The company's success can be attributed not a little to the splendid working staff who are chiefly from the British Postal Telegraph Service." This may be said of all the cable companies.

Really one can hardly accept the supposition that because relatively few telegraph clerks resign, a veritable Utopia must exist in the Postal Telegraph Service.

The other contention is that, so long as clerks can be obtained at the present salaries, there is no need to raise the terms. By a parity of reasoning, it might be contended that because women working upon the making of match boxes for over 100 hours per week could be obtained for a wage of 4s. weekly, there was no need to raise the terms. Or because London seamstresses can be induced to starve on a wage of 12s. for a week of 70 hours, they are well paid. Because 150 persons apply for a post as foreign correspondent at 30s. a week, does it prove that 30s. is an adequate remuneration? This is commonly known as the sweater's argument. It was while such unenlightened principles guided the commercial world, that the "Song of the Shirt" was written. It is against such principles that all recent labour legislation has been directed, and against the application of such principles to State employment, it is the duty of all Englishmen to fight.

I thought it well before entering on the more detailed exposition of our claims, to deal with these general principles. Telegraph clerks feel that the Government should indeed be among the first flight of employers, and one of the duties of intelligent Government should be to keep its own servants abreast of the times. That they have not retrograded in 16 years, whilst all the rest of the world has progressed, is not a cause for satisfaction, self-congratulation, or pride. That they have not progressed is rather a cause for shame. To fall back on the effete principles of an inhuman political economy to justify parsimony, is unworthy of a model employer. The duty of the State is rather to show an example of humane dealing to even its most insignificant employé, and thus constitute itself a model which other employers can copy, to the benefit of justice, humanity and progress.

(*To be continued.*)

NEW PATENTS AND ABSTRACTS OF PUBLISHED SPECIFICATIONS.

NEW PATENTS.—1898.

[*Compiled expressly for this journal by* W. P. THOMPSON & Co., *Electrical Patent Agents*, 322, *High Holborn, London, W.C., to whom all inquiries should be addressed.*]

16. "Improvements in the manufacture of diaphragms for electrolysis." J. W. TOWERS. Dated January 1st.

26. "An improved construction of and method and means of laying underground electrical cables or conductors." T. F. J. TRUSS. Dated January 1st.

45. "Electric switch apparatus for railways to enable train to receive currents from signal station when in contact with its electric current conductor (especially useful during fog)." W. T. BRAIN. Dated January 1st.

58. "Improvements in rail joints for electric railways." M. BARSCHALL. Dated January 1st.

67. "An improvement in holders for electric glow lamps." H. C. GOVER, C. F. PROCTOR and W. G. PIPKIN. Dated January 1st. (*Complete.*)

80. "Improvement in electrical advertising devices." G. A. LESIEUR. Dated January 1st.

121. "Improvements in electric meters." E. BATAULT. Dated January 3rd.

122. "Improvements for separating stable or other salts and generating electricity." D. F. SINCLAIR. Dated January 3rd.

124. "Supporting electric accumulators for electric traction purposes and the like." K. BOWEN. Dated January 3rd.

125. "Speed regulating switch for electric traction." K. BOWEN. Dated January 3rd. (*Complete.*)

143. "Improvements in electric arc lamps." W. J. DAVY and G. T. DAVIES. Dated January 3rd.

148. "An improved electric terminal." L. RIDOUT. Dated January 3rd.

156. "Improvements in the method of fixing and suspending bare electric conductors." A. B. BLACKBURN and N. H. WHITE. Dated January 3rd.

166. "Improvements in dynamo-electric machines." C. B. CRAWSHAW and C. W. HILL. Dated January 4th.

189. "An improved wire cable coupling device for car or trolley cables and the like." A. KAISER. Dated January 4th. (*Complete.*)

192. "Support for electric lamps or other fixtures." S. S. BROMHEAD. (O. C. White, United States.) Dated January 4th. (*Complete.*)

235. "Improvements in or relating to dynamo-electric machines." R. BELFIELD. (Westinghouse Electric and Manufacturing Company, United States.) Dated January 4th.

242. "Improvements in, applicable to, or connected with targets, mantles, and the like." F. RICHARD and T. LEUTZ. Dated January 4th. (*Complete.*)

305. "Device for preventing the displacement of the roller receiving the current from the cables of electric railways with overhead conductors." P. MEYERSFIELD. Dated January 5th. (*Complete.*)

331. "Improvements in preventing sparking when making and breaking electric circuits." A. MULLER and H. TUDOR. Dated January 5th.

358. "A new process for the preparation of electric paste accumulators." E. KOSEL and F. FRENTZEL. Dated January 6th.

373. "Improvements in insulated and protected conductors for the transmission of electrical currents." G. WILKINSON. Dated January 6th.

398. "An improved electrically-propelled bicycle." S. PREM. Dated January 6th.

435. "Improvements in and connected with primary batteries." S. W. MAQUAY. Dated January 6th.

462. "Improvements in, or connected with, electric mains." G. H. NISBETT. Dated January 7th.

468. "Improvements relating to enclosed motors or dynamos." P. ROSLING and H. W. APPLEBBY. Dated January 7th.

494. "Automatic rheostat for use in starting electromotors." A. EMRICH. Dated January 7th. (*Complete.*)

525. "Improvements in electric signalling." S. P. THOMPSON. Dated January 7th.

533. "Improvements in electric arc lamps." A. J. HILLS. Dated January 8th.

571. "Improved means for making electrical connections upon railway trains." W. BRIERLEY and R. FOSTER. Dated January 8th.

584. "Improvements in underground conduits for electrical conductors." E. STANLEY. Dated January 8th.

586. "Improvements relating to the mounting of dynamo-electric machines." P. R. JACKSON & Co., LTD. and J. S. LEWIS. Dated January 8th.

591. "Improvements in telephone transmitters." A. GRAHAM. Dated January 8th.

ABSTRACTS OF PUBLISHED SPECIFICATIONS.

[*Copies of any of these Specifications may be obtained of* Messrs. W. P. THOMPSON & Co., 322, High Holborn, W.C., *price, post free*, 9d. (*in stamps*).]

1896.

18,319. "A new or improved electric hand lamp for general or special purposes." A. J. WESTMANCOTT. Dated August 19th, 1896. Relates to a portable incandescent electric lamp more particularly for use as a cycle lamp or a policeman's bullseye. The shell is fitted with partitions which leaves a space at the back for an accumulator, and a front space for a lamp which is suspended by its leads. The terminals of the accumulator rest in socket blocks mounted on an ebonite slide. From one of the blocks a connection leads to the switch and thence through the lamp to the other block. The switch is also mounted on an ebonite slide.

18,364. "An improved electric motor or dynamo-electric machine." J. T. KNOWLES. (J. H. de Thierry, Italy). Dated August 19th, 1896. An electric motor for use in the propulsion of tramways, vehicles, &c., and capable of being employed also as a generator is composed of two independent armatures having their axes of rotation parallel and a single field-magnet the winding of which is arranged symmetrically with the armatures and in planes parallel to their axes. The magnetic circuit is completed by a ring and a single or double pole-piece.

18,485. "Improvements in acid-proof electrical non-conducting articles and composition therefor." W. MORISON. Dated August 20th, 1896. A plastic substance, which is both an acid-proof and electric insulating composition suitable for making cases for galvanic batteries and for other purposes, consists of asphalt or of a mixture of asphalt and pitch, which is melted, and a little gutta-percha may be added thereto and while still hot asbestos is thoroughly mixed with it. The mass is spread on a hot surface and worked, beat, and pounded, and during this process a little sulphur may be worked into it. The article required is made by moulding this composition.

THE

ELECTRICAL REVIEW.

VOL. XLII. JANUARY 28, 1898. No. 1,058.

CONTENTS:

THE ELECTRICAL REVIEW.

Published every FRIDAY, Price 4d.

The Oldest Weekly Electrical Paper. Established 1872.

TO BE OBTAINED BY ORDER FROM ANY NEWSAGENT IN TOWN OR COUNTRY.

OFFICE:—4 LUDGATE HILL, LONDON.

Telegraphic Address: "AGEEKAY, LONDON." Code A B C.

Telephone No. 988 Holborn.

ALL Letters should be addressed to the Proprietors, H. Alabaster, Gatehouse & Co.

ADVERTISEMENT RATES ON APPLICATION.

The "Electrical Review" is the recognised medium of the Electrical Trades.

SUBSCRIPTION RATES.—In *Great Britain*, Post Free per Year, 19s. 6d. To all other countries, per Year, £1 4s.

BINDING.—Subscribers' numbers bound, including case, for 4s. each volume.

CASES.—Cloth Cases for Binding can be had, price 2s. 6d. each.

READING CASES, to hold from One to Twenty-six Numbers until the Volume is complete for Binding, can now be had from the Publishers, Price 6s. or Free by Post (in Great Britain), 6s. 6d.

FOREIGN AGENTS.—*New York:* D. VAN NOSTRAND, 23, Murray Street. *Paris:* VEUVE J. BOYVEAU, 22, Rue de la Banque. *Berlin:* ASHER & Co., 5, Unter den Linden.

Cheques and Postal Orders (on Chief Office, London) to be made payable to Mr. H. ALABASTER, 4 Ludgate Hill E.C.

SHOP MANAGEMENT.

THE termination of the strike has not, at the time of writing, ended the dispute, and we cannot think that the men's executive have been well advised in allowing a capitulation to become a rout, and in making a last stand upon the question of interference with shop management, which they have always disavowed, while throwing overboard the hours' question as of no importance. We need not, however, pause to discuss what was, after all, a mere stalking horse. No one who knows anything of facts has any doubts as to the issue. The socialist idea of bringing all work under control of the nation at large may or may not be good, but whatever its merits, the consummation of the idea is only to be reached by hard work and discipline, by honesty of purpose and of deed. People who condemn socialism when they understand that it implies the obligation of every man to work to his best ability do so because, not being themselves too fond of work, they do not relish a state in which wealth is not a passport to idleness. To them socialism implies tyranny. But on most of us, who depend on our own exertions, the obligation to work would sit very lightly, and were socialism ever to become a working fact we should still find that our manufactories were under the management of the Colonel Dyers as the most fitting men to manage and to secure the largest output in the fewest hours. Anything more fallacious than the belief that short hours are to be secured by restriction of work cannot be imagined. In striving to wrest management from employers, Mr. Barnes has been endeavouring to upset that natural order of things of which an ideal socialism is but the extended application. The workmen of the country have a right to as much of the product of labour as they can fairly secure. To secure this right, they must see to it that production is a maximum. If labour obtains five-sixths of the excess of value beyond materials' cost, it is obvious that, doubling the output, would double labours' share, and labour should, if wise, give to management every aid in securing production even to the extent of demanding efficient management and American methods, which seem to be within reach much sooner than Mr. Burns intended, when he shouted so loudly for them. The immediate present danger, however, is, that the employers are face to face with a new set of conditions. They have trained up a lot of men to do their work, and are about to engage such of the old union men as they can find room for. These old men may look on the new body as enemies to be hounded out by fair means or foul, and there may be many difficulties. We have more than once in the past six months urged the importance of the employers standing loyally by their new men. After previous strikes the new men have been badly treated, and have been individually choked off by the unionists. We have heard of an occasion where, after a strike, on the re-entry of the men, a union man has deliberately ousted a non-union man from the machine to which he considered he had the right. Our contemporary, *Engineering*, now urges the importance of the protection of the men whose loyalty has carried the employers through the storm. There must be no casting adrift of these men—a dishonourable act, not, says our contemporary, without precedent. In the old days, to discharge a trades unionist who practised intimidation, would have produced a strike. Intimidation may again be attempted, and it must not be allowed. It must be cut down and stamped out, and ringleaders sought out and discharged. But so also must there be discharged any man weak enough or foolish enough to let himself be made a tool in such practices. Howls about the principles of trades unionism must be strictly disregarded. It must be accepted that if trades unionism requires the abrogation of fair dealing and justice, and first principles, we can none of us recognise trades unionism as anything but a foul and pestilential growth. No more must we hold a candle to the devil in blinking at such evils, even at the risk of a strike. But let us again turn to the other side of the question on which we are also supported by our above-named contemporary, and that is the ability of the management. The first office of management is to manage. Now management in knuckling down to the demands formulated in Stamford Street—formulated simply for aggravation, and on the principle that "the office work being slack, let us see what firm can be annoyed," has abdicated portions of its functions, and was left six months ago with only the name. Management has been too exclusively non-engineering in quality, and the men have found this out, and have on their side employed other men also not engineers, or out of touch with their trade, to make foolish demands. If there is no engineer in a firm, the sooner one is admitted the better it will be for that firm. Mere managers without knowledge are of little good. One such man recently was brought to our notice, who, having asked an engineer to get him out estimates for a certain undertaking, sent it back with the request that the estimate should be halved. Management of this type has the added misfortune that it must open its mouth and show the poverty behind the words. The averseness to the means of wealth, which characterises so many sons of the rich, often happily leads to their entire separation from business, but where the untaught untrained sons remain in a business they do incalculable harm, even when really decent fellows. Men who take the top positions in a huge factory without even being trained in their own works, and with no basis of scientific knowledge, are far too common.

Germany has not grown this class yet. America has grown some of them, but young rich Americans are more averse to work than Englishmen when they do tend to idleness, and they quit work altogether. It is the man who is not such a fool as to live in absolute leisure, yet who has felt it unnecessary to learn as though he hoped to earn £300 a year, that is the bane of our English trade, that falls a prey to the glib-tongued commercial, or that lets slip the valuable invention for lack of knowledge of principles. Shop management can never earn respect unless itself competent in the technicalities of what it professes and claims to manage, or has the good sense to secure competent interested management, and gives the same a free hand. The present is not the time for the *dilettante* in business. By shop management we do not propose to confine the term to the management of the men and the proper rating of machines and piecework prices, but we would include a far wider range. Every well-established shop that has the money to pay for it ought at once to clear out the accumulation of years of odds and ends which collect under benches and tools, and should learn that a scrap-heap is for scrap, and should be periodically sold. All tools ought to be overhauled, and old muscle-absorbing articles destroyed if not cheaply reformable. The power department of many works ought to be carefully considered as to the improvement by the adoption in whole or part of electric driving or gas power in place of steam. We have in mind as we write a new shop of small power where the power is over 100 feet distant from the principal power absorber, where, indeed, it makes very little difference whether power is utilised or the shafting run unloaded. We have another shop in mind where some power must be costing nearly £3 per horse-power week instead of as many shillings. These may or may not be extreme instances. We believe they are common; they come under our notice simply. Want of crane power is another shop evil. We know where the removal of a heavy casting on a truck requires a whole crowd of skilled and unskilled men for a temporary, and, perhaps, only occasional tug. The same would be effected by one or two men with a slowly-turning bollard and rope.

We wish to see shop management alive to all such facts. We want capital to allow management to abolish such extravagancies. Yet we have known a works manager severely handled for spending a few thousands on improvements which repaid themselves in a year. True, an apology followed, but not until weekly returns showed that the money spent was coming back. This was an instance of good management hampered by lack of knowledge on the part of principals, and it is happening every day; and gentlemen of education and ability are dispensed with in frequent cases because they do not bow and scrape to principals of less ability than themselves. But are not all these facts known to every experienced man in some form or other. Nothing of this sort would happen if there were more knowledge at the top, and the education of the working men is by no means the only education wanted. There must be no interference with management; but management ought to be good and intelligent. Is it always so?

Electrical Anomaly and Chemical Constitution.—Certain liquids are found to possess an anomalous absorption for rapid electrical vibrations, and an anomalous dispersion of their electrical indices of refraction (ratio of the wavelength of the vibration in air to that in the compound under investigation). This anomalous absorption appears to be intimately connected with chemical constitution, for the hydrocarbons, the ethers, the ketones, and aldehydes behave normally, but alcohols and acids, and generally compounds containing the hydroxyl group, possess an anomalous absorption. The differences are so marked that in many cases this property would probably be of service in settling vexed questions of constitution. An examination of ethylic aceto-acetate, for example, show that, as this compound possesses a normal behaviour, it cannot be regarded as containing the hydroxyl group. Ethylic asceto-oxalate, on the other hand, appears from the results obtained to contain hydroxyl. An exception to the above rule appears in the case of water, the behaviour of which is perfectly normal. Where an anomalous behaviour is noticed for the liquid, this appears to be maintained also by the compound in the solid state. The above is an abstract of a paper by Paul Drude, *vide* the *Annalen der Physik und Chemie*, 1897 (II.) No. 60, pages 500—509.

OZONE MAKERS.

By E. ANDREOLI.

In a very humoristic article on "Electrical Engineering," published in *Mechanical Engineering* for December last, Mr. James Swinburne disserts on the subject of sterilisation of water by ozone, and he wonders "how it is not put into practice more?"

I cannot resist quoting a few lines of his sarcastic dissertation: "One great trouble in the case of ozone work, is the extraordinary vagueness of the ideas of the worker. An inventor working at ozone seldom seems to know what pressure, what current, or what frequency he wants."

"Neither has he the least idea how much ozone he can make or how much of it goes to annoy the particular little animal it is his mission to annoy."

"Until people are exact in their measurements, there is but little chance of making much progress."

Mr. Swinburne is somewhat severe when he speaks of "people who are not exact in their measurements," but after all he is quite right, and I can only approve of the sentence he passes on the *sans gêne* of certain chemists or analysts in making their determinations of ozone.

Mr. Swinburne no doubt alludes to a process for generating ozone which a friend of his had, and has still, perhaps, under his control as consulting chemist: *Amicus Plato, sed magis amica veritas*. The process which I speak of was said by its directors to give some most extraordinary results, and to beat the record of the world.

Mr. Swinburne must evidently have been scandalised by the following public statement which I have in print before me, and on the faith of which the capital of the concern (Limited) was subscribed: "It is believed that over *25,000* cubic feet of ozone can be produced by the apparatus invented by . . . . which is actuated by an . . . . induction coil or converter, capable of working up to 250,000 volts. Such cubic contents equals *1,250,000* grammes, or *3,362* lbs. . . . . The cost of producing *25,000* cubic feet of ozone per hour and of operating the machinery will, it is thought, not exceed *2s. 10d. per hour!*"

25,000 cubic feet of ozone per hour at a cost of 2s. 10d. What shall we call this? The directors will say that their process is a revolution in the art of making ozone; there are some people who will say that it is a perverted statement; no! it is not a fraudulent representation I am sure. It is most certainly a *bonâ fide* declaration made by a very honest man or several honest men (including the well-known chemist, who ought not, however, to have been a party to the promise of 3,362 lbs. of ozone for 2s. 10d.) who were unaware of the many causes which can completely spoil the results of a determination of ozone. Still, the chemist ought to have noticed that the ozoniser worked too well, and was giving much more than the theoretical yield!

But to return to the sterilisation of water by ozone, things are not done in one day; it takes time to devise commercial ozonisers and to improve them, then to construct new ones, sometimes quite different from the first, to try one after the other several new methods for working it, which often have to be abandoned until an efficient, strong, simple and inexpensive apparatus is constructed which gives a satisfactory output, can be worked on any scale for weeks and months, almost without stoppage, does not need skilful superintendence, and does not get out of order or necessitate repairs.

Had Mr. Swinburne realised the magnitude of an installation for sterilising water, he would have been more indulgent and would have better appreciated the efforts of "the people," as he calls them rather contemptuously, "who work at ozone."

Mr. Swinburne's theory is, that the ozone question is, like many others, a matter of patents, and that it is "because the broad principle is open to everybody that it is not done in earnest." Patents have nothing to do with the development of the application of ozone to the purification of drinking water. Conscientious workers do not hurry to attempt to start installations until they know for certain that their generators are capable of doing the work and supplying in a continuous manner, the quantity of ozone required for the purification of thousands of gallons of water per hour.

Mr. Swinburne must not think that all the inventors working at ozone are ignorant of the conditions required to ensure success. Among the names of the men who have recently devised some new forms of ozonisers we find those of D'Arsonval, Patin, some doctors of the Institut Pasteur, and of Tesla. We have not yet heard anything about the value of their apparatus as commercial generators, but surely such men know what pressure is required, and how to make determinations of ozone. None of them, however, profess to produce 25,000 cubic feet of ozone at the nominal price of 2s. 10d. I insist on this preposterous statement because there is no truth in it. We do not say that the figures have been inflated on purpose for certain specific reasons, but we require a corrected statement of the real output of this too much talked of ozoniser. *Parturiunt montes* . . . how much pure ozone is there in those 25,000 cubic feet of ozone which cost 2s. 10d.?

Instead of lecturing indiscriminately the people who work at ozone, Mr. Swinburne ought to have severely scolded the analyst who allows such wrong statements to fly under his colours.

Mr. Swinburne is the inventor of a condenser and of a transformer well-known all over the scientific world; better than anybody else does he know what an ozoniser, *i.e.*, a condenser must be like. The best man to produce a large quantity of ozone is one of scientific accomplishment like Mr. Swinburne, who is thoroughly master of the theory as well as of the construction and working of condensers and of transformers; he is evidently the right man to design the best apparatus for generating ozone, in which the production of heat will be avoided in the most efficient manner. If ozone is still in its infancy, let scientists like Mr. Swinburne who know what the conditions for favourable working should be, take the matter up, and the problem will soon be solved. Why did he not try his hand at it; surely he would have succeeded, but I confidently predict that he never will be able to produce 25,000 cubic feet of ozone for 2s. 10d.?

Mr. Swinburne does not perhaps realise that it is more difficult to make a good commercial ozoniser than to make a good transformer. What is a transformer after all, if not, as Mr. Swinburne says, an apparatus, *the broad principle of which is open to everybody?* Still it is done in earnest, and, luckily for the ozone industry, efficient transformers are not scarce. Ten years ago there were only small laboratory ozonisers, such as the Siemens, Berthelot, Thénard, Houzeau tubes; when Mr. Swinburne constructed his first high-tension transformer, there was not in all the world a single commercial ozoniser capable of producing cheap ozone. We have now some good, strong, efficient ozonisers, and also some excellent transformers. We can start ozone installations of 50 or 100 kilowatts and undertake to apply ozone to any staple industry or to the sterilisation of water. This, after all, is not too bad, and "ozone makers" may say that they have done something.

Is it an easy thing to ascertain the pressure required to produce the maximum yield of ozone? One must not believe that algebraic equations will enable anyone to do it. They are peculiar, the properties of this substance isomeric with oxygen, which is the sole element of ozone and which is regenerated from it. Ozone is formed under the influence of electricity which so often supplies the complement of energy required to generate substances formed with generation of heat. Ozone is formed with absorption of heat which it stores under the influence of electricity, and we are in presence of a body which is more condensed than its element and which absorbs heat instead of generating it, as is the case with condensation.

If the formation of ozone was due, not to a rise in temperature, but to the passage of electricity through oxygen, there would be a ratio between the proportion of the ozone formed and the quantity of electricity consumed, but there is nothing of the kind, as the formation of ozone is intimately dependent on the production, in oxygen, of electrical discharges which render it luminous, and at the same time cause a considerable rise in temperature, and the electric conditions of the formation of ozone are so little known, that it is still a question whether the silent discharge acts as an electrical phenomenon or as a heater of the oxygen which it traverses.

Then we have to consider the changes of the electric tension during the interval of the sparks and of the alternations.

Are the chemical reactions caused by these alternations and by the resulting collisions and molecular vibrations, or are they simply due to a potential difference, to an orientation of the gaseous molecules without any intervention of voltaic current, of rise of current caused by the sparks or of the frequent variations of current?

We may consider the *rôle* of the silent discharge in the isomeric transformation of oxygen to consist merely in placing temporarily this gas in such a condition that it is susceptible of fixing heat.

These are the data on which the ozone makers must determine the pressure required for the working of their ozonisers. They have besides to take into account the *rôle* of the dielectric and of several other factors, and it is no exaggeration to say that they have to contend with some intricate difficulties, and that if they only succeed partially, those "people" deserve something better than to be sneered at, who produce, on a commercial scale, ozone, that body of which Frémy said that oxygen is the greatest discovery of the last century, and among the conquests of modern chemistry there is not one more important than that of ozone.

ISOLATED PLANT v. CENTRAL STATIONS.

The question of isolated plant *v.* central stations is one which is very seldom discussed or much spoken of in the electrical press. It is one, however, which exercises the central station engineer, especially in manufacturing towns, more than he cares to admit.

This is true, more especially in cases where arc lighting is employed. A slight variation in the voltage is not so noticeable as in an incandescent installation; consequently in large works, the machinery of which is operated by a modern engine, well governed, a dynamo or dynamos can be run off a shaft, like any other machine.

It is useless to disguise from ourselves this fact, for when we remember that a variable drive in, for instance, a spinning or weaving factory, would be very detrimental to the delicate threads and fibres manipulated, we can readily realise that a dynamo would be afforded a sufficiently steady drive to ensure a practically constant voltage.

By this means the primary cost is reduced, and the subsequent item of attendance also reduced, for if no separate engine be employed no wages would have to be paid for this work. The dynamo is no longer an experimental toy, but a machine which can be depended upon to do its work well with the minimum of attendance.

When the cost price of the Board of Trade unit generated is compared with the price charged by most electricity supply concerns, it is not surprising to find that many large consumers of electricity prefer to generate their own current, and to put up with, perhaps, a little inconvenience at rare intervals in the shape of brief irregularities in the supply, although these could easily be provided for by having a connection from the electricity supply mains or by having a battery of accumulators for reserve and supply when the main engine was not running. The demand for current in factories, large houses of business, and the like, takes place, as a rule, at the same time as most other consumers, consequently a reduction in the price cannot be claimed by coming under the head of "long hour customers." An alternative plan of installing an accumulator and charging it during the daylight hours, or hours of minimum load, and using it to supply the current when the light is required is open to grave criticism. The current thus supplied would enable the consumer to buy his current very cheap, and the effect on the load curve at the central station would be very beneficial, but it is very doubtful if, when the efficiency of the present day accumulators and the heavy depreciation of the same are taken into account, any real saving would take place.

We have no desire to preach isolated plants, but we cannot close our eyes to the fact that electricity is too dear at present, and we must not be surprised if probable large consumers prefer to undertake their own supply, just as many large concerns manufacture their own gas.

When electricity is sold at a popular price, especially in provincial manufacturing towns, then may we expect to see the private consumer drawing his supply from the mains which pass his door, and gladly putting on the shoulders of those whose business it is to supply electricity the responsibility which he has taken upon himself merely because he could supply himself with electricity at cost price.

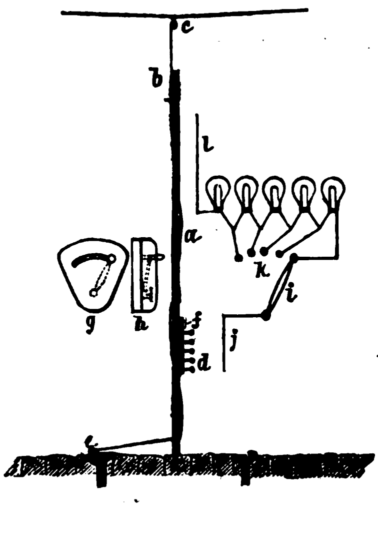
In comparing the cost between the two systems, it must be borne in mind that the cost of the wiring and lamps is the same, in fact, no notice need be taken of any expense incurred from the supply company's terminals or the terminals of the dynamo. The interest and depreciation is the same in both cases. The interest on extra capital spent only applies to the dynamo, batteries, switch gear, and engine, if one is employed. There are hundreds of private installations spread about the country which are giving perfect satisfaction, and it is a very serious question for the dispensers of electricity to consider the elimination of these installations by inducing consumers to buy their current, and this can only be done by a reduction in the price charged for electricity, bearing in mind the fact that the more current sold the cheaper it can be produced and distributed.

HOME-MADE TESTING RIGGING.

"Superintendent" writes to the *American Electrician* as follows:—

For testing the drop along a line of road, nothing goes ahead of a good voltmeter, but it is not always expedient to send out such an instrument, and for constant use in a "hurry-up waggon, the life of the best voltmeter is short. A good home-made rigging for this purpose is illustrated by the engravings herewith. It consists of the pole, *a*, which is preferably long enough to reach from the ground to the trolley wire. A jointed pole may be prepared for this purpose, and quite a short pole can be used on a pinch. The bare contact wire, *b*, is bent into the form of a hook, so as to catch over the trolley wire, *c*, and hold the pole and rigging in position.

A bank of five lamps, shown at *d*, is connected in series with a wire running up the pole to the contact wire, *b*. Another wire is carried down the pole, through a rubber tube, and connected with another contact wire which is put on the rail, *e*, thus completing the circuit through the lamps from trolley to rail. The brightness of the lamps tells how the



voltage is. This is, however, a rather discouraging test, and may be made much more valuable by adding a kind of a rheostat whereby some of the lamps may be cut out until the remainder glow up to full candle-power, thereby giving a better clue to the voltage at that particular piece of track.

This arrangement is shown in the detail drawings. The rheostat shell, shown at *g* and *h*, may be the case of a played out voltmeter, with the glass removed, but a wooden case, or one made of fibre is better as there is less danger of the instrument getting grounded, thereby giving the operator a test instead of the line. Five contacts are arranged as shown in the upper part of the detail, *g*, and a spring arm is made fast so as to sweep over these contacts. The side view, *h*, shows how the arm is made part of a spiral coiled around the stout screw, and how the spring arm is moved by an insulating handle which projects through the top of instrument case.

The method of connecting up lamps is shown at the other side of the drawing, where *l* is the wire coming from the trolley and running to the first lamp. All the lamps are wired in series in the usual manner, the last lamp being connected to the last contact of the rheostat box. Branches are taken off between the lamps, and run to the other contact points as shown in the engraving at *k*. The wire, *j*, is carried to the rail contact, and as the lever, *i*, is moved around, it successively cuts out the lamps by short-circuiting them.

In use, the pole is set up and the contacts made, and if the lamps do not go up to full brightness, the rheostat lever is moved a point and the lamps carefully watched. If the four remaining in the circuit go up too bright, the lever is released before the lamps have a chance to damage themselves much, but if the four do not go up to full power, another move of the lever cuts out a second lamp. This can be continued until only one lamp is left in the circuit, if necessary, but there will be a pretty big drop or a bad short circuit somewhere on the line when all the lamps but one can be cut out.

The object of having the spring lever to the rheostat is to prevent the burning out of the lamps, which would surely happen if an ordinary form of rheostat were used. The current could not be cut off quick enough when the limit of lamp cutting out had been reached, and away they would go. But with the spring rig, as soon as a man lets go the handle, all five of the lamps come right into the circuit again and no damage will be done from leaving the lever turned.

A very desirable modification of this rig is to put in 50-volt lamps instead of 110. Then the number of steps could be increased and the testing made so much more elaborate. The 110-volt lamps would burn brightly at 550, 440, 330, 220, and 110 volts respectively, but with a bank of 11 50-volt lamps tests could be made at 550, 500, 450, 400, 350, 300, 250, 200, 150, 100, and 50 volts potential between rail and trolley wire. With three or four 50-volt, and the others 110-volt lamps, a very good combination could be made with close readings of the higher voltages.

MACHINERY AS A FACTOR IN CHEAP PRODUCTION.

During the progress of the recent strike it became every day more plain that the heart of the whole matter was the use of machinery, curious as it may seem to-day when the whole world is using automatic machinery which was practically invented in England. There is, indeed, no engineers' tool of a labour-saving type but had its origin in England. The slide lathe, the planer, the steam hammer, to name three prominent machines only, all were born and perfected in England, which was the birth-place of the steam engine and the locomotive. Yet it is Englishmen who have struck against machinery just at the time when that machinery has helped to make so keen a competitor of the foreigner.

The rights of labour supposed falsely to be interfered with by machinery are seen to be rights of a very narrow class, the members of the A.S.E., irrespective of their skill. The outsider, and especially the poor labourer, has no rights. Mr. Maxim, in the *Engineering Magazine*, shows how cheap production has only been possible by the use of machinery, and he states:—

"An unskilled mechanic is as much a citizen of the country in which he lives as anyone else, and is entitled to the same degree of protection and consideration as is accorded to the skilled mechanic." The skilled mechanic has no right whatsoever to create any artificial system which will restrict the liberty or the facilities of the employer to employ this important class of the community. Every man is apt to look on a question from the point of view of his own immediate interest. Seeing how very large is the labourer class, let us try to look upon the machine question with the eyes of an intelligent and fairly educated labourer. We see a body of skilled workmen bound in a narrow guild, and claiming for themselves, to our exclusion, the right to perform certain work. We see the invention of certain machines, capable of greatly cheapening the production of this work. To fix ideas, we will suppose the particular work to be the manufacture of sewing machines, and their price is £8. About one house in every ten possesses a sewing machine in the district in which we live, and these houses are the homes of the favoured skilled men.

We see that if the production of sewing machines can be cheapened so far as to enable them to be sold for £2, there would be probably eight times as many in use, for they would now enter the homes of our own class. But the favoured few forbid the cheapening to be done. They say it will throw some of them out of work. Yet by the use of machinery, which we are competent enough to work, we labourers would add considerably to our wages, and would become purchasers of the very goods we make, and in doing so, we would actually cause the employment of more of the favoured class than were employed in making the machines to sell at £8. Is it likely that we look upon the skilled men with friendship? They grudge us an extra few shillings wages, though, by earning them, we help to make more employment for them. We see all these things plainly, because so many of us are students, readers, amateur naturalists, botanists, or geologists, and have better trained minds than your pot-house trades unionist, who, as a rule, is so puffed up with pride of position, that he does not think it necessary to do anything outside his trade.

Such, to many intelligent labourers, is the appearance of the machine question and trades unionism. It is a bar to his own better living to which he has a right. Mr. Maxim considers it would cost about £60 to make a Winchester rifle by hand, and only very skilled men could do it. They would only be saleable, as a luxury, to the rich, and about 20 mechanics would probably fill the market.

By automatic machinery their cost is about 24s., and they are sold retail at £3, in place of at £100 at least. Unskilled men and boys make them. There is not a large proportion of skilled men. Where are the skilled men? Chiefly making the high-class machines, gauges, tools, &c., without which the unskilled could not work. The result is, in place of a small trade employing 20 skilled men there is a huge trade employing thousands of unskilled men and hundreds of skilled men on accessories, and Winchesters are everywhere.

It is the same in watchmaking. Watchmaking machinery was invented in England. We have seen the drawings of the first. But they were only taken up in America, and English watchmaking almost died until Rotherhams, of Coventry, went one better than even the Americans, and in watchmaking England is, we believe, getting back her own.

Before the era of machinery, the working classes simply lived and had a roof over them. They were not purchasers of anything beyond mere necessaries; they were producers only, and at so slow a rate, that any sale at all for their productions was only possible by reason of the labour being very poorly remunerated. But by reducing the labour cost per item, production has been so cheapened that the producing class have become purchasers, and wages have perforce increased. The appetite for luxury grows, and the learning to consume has widened markets. False socialism—thrifty in other things besides soap and water—tends to narrow markets. True socialism, which is opposed to thrift, makes everyone a consumer to the extent of his income. The inculcation of thrift is really a mistake. If every man spent the whole of his income as he received it, there could be no slack times in trade; there would be a constant and steady flow of business. We have every sympathy for that socialism which would compel every man to work and support the infirm, the aged, and the sick, for such a policy would destroy the necessity for thrift, which, whether it be the putting by of the daily penny or the hoarding of the millionaire, is bad for trade. We do not feel the full evils of thrift, because hoarded money is very largely entrusted to banks which use it in trade. Thrift carried to extremes at short notice becomes panic. To hear the term Socialism applied to the ignorant follies of latter-day trades unionism is very vexing to the soul of the real socialist, to whom socialism is not synonymous with either communism, anarchy, or laziness. True socialism would be very irksome to the naturally lazy man.

Mr. Maxim says, with some truth, that the manufacturer—he would have better said some manufacturers—is apt to look on his works as a necessary evil, in which he takes very little interest, and from which he hopes to be released and to retire. He does not identify himself with his workers, who look on themselves as slaves to their trade, and so on. A good deal of this has a basis of truth, even if spoken with that disagreeable spirit of spreadeagleism which marks Mr. Maxim as an American. We do, however, agree with him that a destruction of old tools would be a great benefit. Long after the modern three-grooved tap had been invented, there was an old four-flat $\frac{7}{8}$-inch tap in a shop we wot of that would not be lost, and cost pounds in wages that would have bought new ones; but it was of magnificent material, and stood wonderfully, and so was kept at work. This sort of thing goes on on a large scale, but is, of course, wearing out, and we fancy there are a goodly number of English shops where freedom reigns, and modern methods prevail, but of which the proprietors say little.

Mr. Maxim's experience at his own works has been very vexatious in the matter of union interference with automatic machinery, such as running a lathe all day without a cut, and he strongly advocates the counter move of the Employers' Federation.

It appears that several of the labour leaders have come from Mr. Maxim's own works, and he naturally has something to say of their methods. He contrasts the understanding between masters and men in the workshops of America and Germany with the lack of it in England, where no understanding can be arrived at on the question of cheap production. It were useless to build fine shops and equip with the best tools, unless labour will assist to make those tools do their duty. This could, he thinks, easily be managed, but for the professional agitator, who aims to teach the men that an employer is of necessity a criminal. The first strike at Crayford—Mr. Maxim's works—was due to their refusal to promise that no piece work should ever be done there. They obtained a lot of Frenchmen, who, finding they could only work 54 hours a week, set up little works at home to fill in their time and made electric bells, &c., just as the Woolwich men, on eight hours, are making bicycles and interfering with the local makers. Mr. Maxim would abolish protection in America as no longer, if ever, necessary, but he evidently shares our opinion in looking on Americans politically as fools influenced by political agitators, in the way Englishmen are fools to the labour agitator.

TECHNICAL LITIGATION AND THE QUESTION OF GOOD WORK IN HOUSE WIRING.

By V. ZINGLER, A.I.E.E.

A recent case in the Law Courts brought both of the subjects involved in the above heading into prominence—into unfavourable prominence, it may be said—and into utter confusion and indefiniteness. Into unfavourable prominence, because it only served to demonstrate again the oft-repeated assertion that the Law Courts is not a place for referring these cases to, or the law (as it now stands) a fit and proper instrument for deciding such cases on their merits; it also brought before the public what must be considered a curious state of things in the house-wiring question, calculated to alarm them as to the safety of their houses, and to surprise them in the differences of opinion of the experts (surely in this case we cannot say, "*in the multitude of counsellors there is safety*);" into confusion, because to anyone present it was apparent that the state of both the exponents of the law—who did not understand what they were talking about, and of the twelve good men and true, who did not understand what they were listening to—was "confusion worse confounded;" into indefiniteness, because it showed that technical litigation is an uncertainty and a lottery, and the question of good work in house wiring is as far from being standardised as ever.

We may deal with both the subjects of the title separately, in order not to still further confound the two issues.

To take technical litigation first. The case was of the sort that is constantly coming up in other trades—work alleged to have been negligently done; part payment stopped from the account, and process to recover same. The verdict was no doubt arrived at, after due deliberation of the many points involved, so far as they presented themselves to the jury, after filtering through counsel and judge. It is with the conduct of these technical cases that we have to deal, and the aspect of this case, both from the point of view of conduct, and of the ultimate feeling of the technical spectator, that the whole thing was a farce, is deplorable. We assume no partizanship; one side may have been as right as the other; both may have been equally wrong. But the fact remains that such a case as at present tried is a farce, and undoubtedly the result is often a miscarriage of justice. For what do we find? A body of twelve men picked indiscriminately from the classes and the masses, the odds immense against any one of them understanding anything about electricity, or whatever science the particular case before them may involve. Twelve men, whose only qualification is that they pay rates, and can, perhaps, be credited with sufficient common sense to discern whether a witness is honest or not; and even here they may fail, if the examination is on a technical subject. Then the counsel, who are no doubt admirable men in their way, but who understand little or nothing about science. These gentlemen have to be stuffed up by their respective witnesses, and endeavour in a few hours to grasp and hold forth on matters which it takes an average man years to acquire. And finally the judge, arrayed in babe-like innocence, who makes jokes at which everybody is expected to laugh, and then sums up on what he has learned from counsel and terrified witnesses, who, by methods of counsel with which it is proposed to deal, have unwittingly been made to perjure themselves again and again. And on this the jury find a verdict—not before they have, perhaps, shown their good sense as honest men by saying that they cannot agree, and so endeavouring to avoid pronouncing a definite opinion on subjects with which they are not competent to deal. But this will not do for the judge; he not only does not wish to run up the costs of the case by discharging the jury, and he has no doubt had enough of the case himself. And so the jury are bullied a little, and as they are only human, and often hungry, and have wives and families to whom they wish to return, they eventually agree on a verdict, but compromise with their consciences by leaving the contending parties to come to some arrangement as to terms.

Now we may ask: Is this fair? Is this the proper way the law should be administered? Most decidedly it is not; but then do not the parties in the case know this? If both sides are technical men they know it as well as any reader of this journal; they know exactly what they may expect to get in the way of judge, counsel, and jury. Then why do they go to law at all? Why do they not get an arbitrator to decide the case between them? Why do they not both decide on a man who could be depended on to hear both sides in all they have got to say, who, moreover, could understand what they are saying, and who would be competent to decide the case on its technical merits and not on side issues? There comes the rub. If it were possible to appoint such a court, whose decisions in technical cases would meet with the approval of outside technical men, how many such cases would come before it? It is probable that the office would be a sinecure, and many cases which—if the judge could only see their "true inwardness"—would be dismissed under the Vexatious Actions Act—would never see the light of day at all. No; it is the glorious uncertainty of the law as it now stands, and the sporting (?) instinct of the English nation, which drives these cases into the Law Courts.

If A thinks that B has infringed his patent, is it not better to challenge him to a sort of game of chance in which A or B will ultimately win all the stakes, and to engage a band of professionals on each side, than to argue the matter out before an impartial expert? Most decidedly it is more exciting, and in the generality of cases it is the man who is in the wrong, who knows he is in the wrong—who brings the action. It is a game of bluff, all or nothing. The challenged party may know he is right; he may know he is wrong; at any rate, he thinks, the odds will be even either way; he is on his defence; if he compromises he will lose caste, and perhaps only gain half of what he may gain by fighting. So there is a rush to engage the best players; not necessarily those who know the game best, but those who can play it in the most audacious style, who can "beat" their opponents by all manner of clever tricks, who can make them actually play on the wrong side by mistake. That is what fetches the public, in the shape of the jury; that is what decides the case. Or take another example: A makes a contract with B that B should perform certain work. When the work is said to be finished, A is of a different opinion and presses for what he considers the interpretation of the contract, and perhaps thereby accidentally makes some legal technical mistake. B then brings an action against A for fulfilment of his part of the contract, namely, payment which may have been withheld. Why does B not suggest appointing a technical arbitrator? Because he knows he would not win his case. But as the matter now stands, he is aware that A has made some mistake which will most likely be the cause of his paying the costs; therefore B's position if he loses the action will be no worse than if he did not bring it at all. On the other hand, if he wins the action he is in the same position as if he had fulfilled his contract properly. The case is fought out on the same lines as indicated before; counsel get hold of side issues, twist them about, turn them inside out, and in the end the real question before the Court, which the Court never understood, is quite lost sight of.

Then as to the methods of counsel. The gentleman in charge of the case is no expert; what he has learned, he has learned quickly and superficially; he does not grasp the technicalities of the case as he should, and when he has finished examining a witness—perhaps a voluble witness—he has perhaps done his side more harm than good—that is, if the other counsel is sharp enough to take advantage of it. He asks the witnesses technical questions which they have suggested to him in private, but has no idea what they mean, and therefore no power of following them up. He then goes out of court for an hour or two, perhaps to take another case of quite a different nature, and then his junior proceeds. If this gentleman has not been present at a consultation with witnesses beforehand he knows even less of the matter. And then the senior counsel returns, and addresses the jury for his client. If his junior has made some points during his absence, he does not follow them up, and the jury lose sight of them.

In cross-examination the farce becomes even worse, for the one and sole object of counsel is to make witnesses confused. This may be quite legitimate if the counsel has a thorough grasp of what he is talking about. But in technical cases the witness knows more about the matter, and may often give an answer which may "floor" counsel, who then says, "Well, I do not understand anything about that." In order to avoid such *contretemps* the method adopted is very frequently as follows: Counsel asks witness a technical question of an utterly meaningless and childish sort—in fact, having no connection with the case. Witness looks perplexed; he asks for the question to be repeated. With a meaning look at the jury, counsel repeats it; the witness looks more confused; the jury gradually wake up to the fact that this is a discreditable witness; the witness says he does not see what this question has to do with the case, and of course the jury think this is an attempt at evasion. Counsel says that he (witness) is not the judge of that, and so in despair witness appeals to the judge. The judge, waking up with a start, suggests that witness should have patience with counsel and reply to the question. The question is again put; witness hesitates. Now is the time for counsel; throwing down his brief, he roars, "Answer yes or no, sir!" Witness, now utterly helpless, says "Yes" in a reluctant way, and counsel, smiling at the jury, says: "Gentlemen of the jury, this witness is an expert." The jury look very wise and make rapid mental notes. And so the case goes on, much to the disgust of technical men in court who may just have looked in to hear what is going on. One expert swears that there is no harm in doing a thing, which it is shown afterwards that he has privately condemned, and which no expert worthy the name would permit. Another tells jury gaily that fire insurance rules are only got up for fun, and that nobody works to them, or some such nonsense. Counsel tries to show, by garbling technical requirements, that these rules contradict themselves and are therefore valueless. What, says he, is the use of permitting twisted flexible wire to be used if the other wires may not be bunched? It is an anomaly. When the question is raised of passing flexible wire through holes with sharp edges in a metallic back plate, and the consequent danger from short-circuiting, counsel, in cross-examination, wisely holds up a wooden patress and wants to know if wires are not passed through this and if it is not inflammable. Witness agrees, and counsel looks still wiser at the jury, who again draw their own conclusions. Truly remarkable! And witness's counsel never attempts to put the matter right; the reason is very simple—he does not see it.

On side points are cases fought and won. Is it not, indeed, time that something should be done to appoint either a special judge with a knowledge of elementary science, or a technical adviser to the existing judges? Should a case of this sort be heard before a jury? and, lastly, is it decent, is it honest to their clients, for barristers to accept briefs and fees, for cases of this sort, unless they have previously attended a course of elementary science? If any scientific man is not sure of his answer, let him go to the Courts when a technical case is on, and he will speedily come to a conclusion, and will probably agree with Bumble that (as it affects technical cases) "the law is a hass."

(*To be continued.*)

DR. LODGE ON WIRELESS TELEGRAPHY

Last Friday, Dr. Lodge described at the Physical Society some experiments that he has recently been making on telegraphy without connecting wires. He objects to the term "wireless" telegraphy which has been commonly applied to this kind of signalling, since there is considerable amount of wire about some of his apparatus, but we may stick to it for the present till the scientists have agreed among themselves as to a better name.

Dr. Lodge's efforts have been more especially directed to the design of a transmitter and receiver which can be sharply

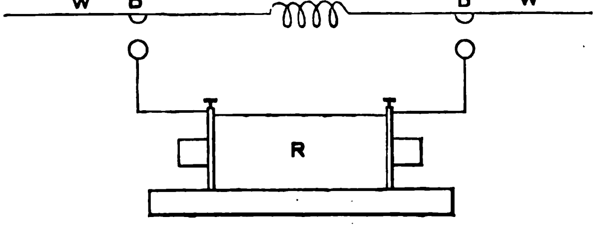


Fig. 1.

syntonised, to enable messages to be sent to a definite point. As is well known, the Marconi apparatus is defective in this respect, for the reason that the waves which it generates are very quickly damped. Theory indicates that the damping can be reduced by increasing the capacity and the self-induction and reducing the resistance of the conductors in which the oscillations take place.

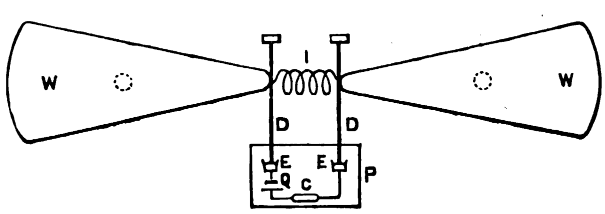

Fig. 2.

A large number of arrangements were described to attain this end. In figs. 1 and 2 we give a diagrammatic illustration of one of the best of these instruments, which is capable of being used both as a transmitter and a receiver.

Fig. 1 may be taken as a plan, and fig. 2 as an elevation. Two wings, W W, of thick copper plate about 6 or 8 feet in length, and triangular in shape, are connected by a coil, I, consisting of a few turns of thick copper wire.

When the instrument is used as a transmitter, sparks are discharged from an induction coil, R, across air-gaps to knobs, B B, at the centre of the wings. This causes a current to surge across the coil, I, from one wing to the other, and send out powerful and persistent Hertzian waves in every direction.

In fig. 2, the apparatus is shown connected up as a receiver. Two sliding rods, D D, pass down through apertures in a metal box, P, and dip into mercury cups, E E, at the terminals of the circuit containing the battery, Q, and coherer, C. The sliding rods, D D, are drawn up, and the metal box completely closed, when it is desired to use the apparatus as a transmitter.

A number of methods of connecting up the coherer and the telegraph instrument were brought forward by Dr. Lodge, which we hope to describe more fully later on.

Dr. Lodge gave no results as to distance telegraphed by his apparatus, but he appears to be at present conducting a series of experiments, the results of which, we hope, will soon be published.

CORRESPONDENCE.

Dynamo Design.

In reading through Mr. Zingler's two articles on "Dynamo Design," I have been struck by several points which, in the interests of the would-be designer, require further light thrown on them. These points I will take up in the order in which they occur in the papers. We are told that the symbol *c* represents the number of convolutions or bars. Now it is quite evident that it does not represent both these, for in a drum armature, with which he is dealing, there must be at least two bars to a convolution. As a matter of fact, the use of it in the equation

$$N = \frac{E \times 60 \times 10^8}{n\,c},$$

tells us that it is the number of bars. A little later on, however, we are told that it should not be less than 40. This corresponds to 20 commutator parts, which is surely too low a number for the satisfactory collection of 400 amperes at 80 volts.

Having assumed a value for *c*, in a seemingly very arbitrary manner, a value for N, the total flux through the armature is deduced from the ordinary formula, and then 10 per cent. is added for armature and demagnetisation losses. How do the latter affect the value of N? I have always understood that the formula

$$N = \frac{E \times 10^8 \times 60}{n\,c},$$

where E is the actual E.M.F. generated, *i.e.*, the terminal P.D. + the loss of volts due to the resistance of the armature, was absolute and required no correction.

There is an apparent discrepancy between the first and second articles. In the first, the size of the armature core is taken as 15½ inches diameter × 16 inches long, whereas in the second the length of the pole face is elaborately worked out, and given as 18½ inches.

This, it is needless to say, will scarcely make a satisfactory combination; in fact, it is very desirable to keep the length of the pole face rather less than that of the armature core, in order that the end plates may be kept as much out of the field as possible.

The first paragraph under the head of "Ampere-turns" is very loosely worded. The products of the magnetic reluctances, and total flux, N, do not give the ampere-turns required, but only the M.M.F.; and, moreover, to be strictly accurate, it is the sum of the products of the total fluxes in each portion of the magnetic circuit, and the corresponding reluctances that give the M.M.F., since N is by no means constant throughout the magnetic circuit.

Again, under the same heading, in calculating B in the air-gap, the author neglects the fringes in arriving at the polar area, and so gets a value for B of 5,750; whereas on the preceding page, by allowing for fringing, he has a value of 5,000 for B, with the same value for N. Why this difference of treatment?

Another point I must take objection to, is that in calculating the field winding, no account is taken of the increase of resistance of the field when the machine gets hot. Consequently the ampere-turns will be too low (quite 15 per cent., with the radiating surface allowed) after the machine has been running for some time.

It is in calculating the ampere-turns required that we must add a sufficient number to compensate for the demagnetising effect of the armature.

It is doubtless a slip of the pen when we are told that the watts per square inch should not be higher than 1·5. I take it that what was meant was, that the square inches per watt should not be less than 1·5.

In conclusion, I would point out that the one point, more than any other, which determines the size of a machine, is not touched upon, or, at most, very indirectly. I refer to the heating of the armature. True, we are told to take a current density of 1,500 amperes per square inch, but no account is taken of eddies and hysteresis, the former of which, even at moderate speeds, contribute a very important part in the heating.

Amicus.

I will endeavour to reply to "Amicus" as briefly as possible. "c = No. of convolutions or bars," was meant to imply—as referred to a wire wound or bar wound armature *generally*. The terms are perhaps vague—conductors would be better. The same applies to the next remark, which referred to armatures generally, and not this particular one.

As regards adding 10 per cent. for armature and demagnetisation losses, certainly N would require no correction if there were no losses to allow for.

Any discrepancy between the first and second articles can be accounted for by the fact that the calculation in the first were merely approximate to get a rough idea of the size of armature, with an arbitrary and different number of bars to that afterwards assumed. Certainly in such a calculation something must be assumed.

As regards his remarks on fluxes in different parts of the circuit, I think "Amicus" cuts things rather fine. I can only refer him to Prof. Silvanus Thompson's book.

Turning to the value of B in air-gap, I thought I had made it clear that 5,000 was the assumed induction if there were no fringing. To allow for this in calculating the *effective* polar area B is increased by the usual method to 5,750. This allows for the additional ampere-turns to make good for the lines lost in fringing.

The radiating surface allowed, is certainly not small. The resistance taken was for 60° F. This, together with the fact that a good deal of allowance was made for slack, and only three sides of the bobbin included for the area, will give "Amicus," I think, some volts in hand when running cold at the normal speed.

The remark about watts per square inch, was certainly a slip of the pen.

In conclusion, I can only repeat again what I stated in my article, that the magnetic calculations had only been touched on. Perhaps it would have been better to have substituted the word "winding" for that of "design," in the title.

V. Zingler.

January 24th, 1898.

Shielded Conductors.

In his article under the above heading, which appears in the last two issues of your paper, Mr. Price tells us some true things about buried armature conductors, and illustrates his remarks with one or two well drawn diagrams. But on the subject of eddy currents he seems to have missed the point.

He introduces the question of eddy current heating, and points out that buried conductors give less trouble from this cause than surface conductors, which is, of course, quite true, and a matter of common knowledge. We hope, however, that he is leading us by gentle steps towards a simple and lucid explanation of this phenomenon; instead of which we are compelled to conclude that the line of force—or tube of force—theory which Mr. Price is, apparently, trying to justify, fails us here. But why?

Long before the discussion of magnetic problems and paradoxes became the rage, it was well known that eddy current losses in buried armature conductors were practically negligible; the explanation given being that, whereas in a smooth core armature, the conductors enter and leave the magnetic field gradually, taking an appreciable *time* to do so, in the case of a slotted armature, the lines *snap across* the conductors so quickly that the eddy-current losses are necessarily very considerably reduced.

This explanation may not be remarkable for its accuracy of expression; but surely we are right in assuming that, *for a given E.M.F. generated*, the eddy-current loss in a conductor, depends upon the *time* which it takes in passing into or out of the uniform magnetic field under the poles.

If, in the case of a slotted armature, the magnetic lines which form the "fringe" at the pole tips, may be considered as "snapping across" the whole width of the conductor in an inconceivably short space of time, it stands to reason that, since all portions of the conductor enter or leave the magnetic field almost at the same instant, the work done by eddy currents (quantity of electricity set in motion × mean E.M.F.) will be hardly worth considering.

Mr. Price then deals at some length with Prof. Du Bois' statements anent ring magnets, and with the aid of some more beautifully-drawn diagrams, he tells us many things which it may be useful to know. It is unfortunate that, after all is said and done, we are still in a state of semi-obscurity as to what it is that Prof. Du Bois really *has* observed. One cannot suppress the feeling that it would have been nice to have known this at the beginning.

Then there is Mr. Price's *paradox*. We are told to consider the space between two infinite plane magnetic shells, of which the opposing faces are of the same polarity. These magnetic shells are built up of an infinite number of small bar magnets, placed side by side. It is pointed out that, with such an arrangement, there is no magnetic field, and the question is: Have the bars ceased to be magnets?

That the resultant magnetic induction between the shells would be *nil*, is quite evident; but whether or not the bars have ceased to be magnets must depend, to a great extent, upon the accepted definition of the word magnet.

It is wonderful how a simple analogy will sometimes sweep the cobwebs from a mind which has been dwelling too long upon some apparently involved or obscure point, and the following electrical analogy, though no doubt highly unscientific, may help to guide us towards a solution of Mr. Price's difficulty.

The terminals of two dynamos, which are generating exactly the same E.M.F., are joined together, positive to positive and negative to negative. There is no flow of current, and the question is, have the dynamos ceased to be generators of electricity?

Alfred Still.

"Dynamo-Electric Machinery."

I must apologise for an unfortunate but obvious mistake in the letter you were good enough to publish in last week's issue. The first term in the second example should of course be 2·5, and not ·25.

W. Casson.

New Type of Locomotive.

I, and doubtless many more of your readers, having access to no other engineering journals save the ELECTRICAL REVIEW, would feel greatly obliged by an expression of authoritative opinion regarding the marked statement in the enclosed, taken from the *Glasgow Herald* of 14th inst.—the leading daily, as you may, perhaps, be aware, in the West of Scotland, and usually a tolerably safe guide in matters mechanical. An intelligent locomotive man here, with a lot of practical experience, assures me that N.B. Railway engines, with cranks on the usual "quarter-throw" principle, and wheel-segment balances, give, when running at or close on 60 miles per hour, no indication whatever of "sledge-hammering," as alleged by the *Herald* writer; and one might, indeed, be such excused for feeling surprised if they did. Obviously the solid segments in the wheels of such engines will represent the 180° cranks of Mr. Manson's new type, though being, perhaps as regards centre of gravity, further removed from the axle centre, the stripes which they set up within the axle may prove more injurious to the latter. That they can effect to any great extent, however, the wheel-rims, seems highly improbable. By the way, is it not a misnomer to speak of such engines as "high-speed," their wheel revolutions,* at 60 miles per hour, being only about 251 per minute?

E. M'Lean.

[In the arrangement proposed by Mr. Manson, the balance weights in the wheels may be entirely omitted, and the two oppositely moving pistons will balance one another in a sense, but unfortunately the two pistons are not in the same plane—vertical—and they will cause more or less tendency to vibrate the whole machine in a horizontal direction. This produces what is known as *nosing*, the front of the locomotive swaying from side to side.

The so-called hammer blow, due to unbalanced vertical action, has been awarded far more attention than in England. The reason is three-fold. In the first place the reciprocating parts of American engines have been very clumsy, and therefore excessively heavy; secondly, the wheels have been very small, and thirdly, the rigid economy in American bridge-work, combined with numerous long spans, has enabled the unbalanced action to be markedly shown. It has been suggested to employ three or four cylinders in a locomotive, two outside the frames, and the remainder inside. The two outside cranks would both point one way, while the inside crank or cranks would point the opposite way. The total inside reciprocating weights would exactly balance the outside, and a perfect all-round balance would be practically secured.

The only objection to such a system would be that the engine would not start when on its dead points. This could be overcome by allowing the two sets of cranks to vary from perfect oppositeness a few degrees only, being content to allow a very slight departure from perfect balance; or by the use of a small engine to turn the large one off the dead point as usual in large stationary engines. This idea is perfectly feasible, but probably not one locomotive engineer in a hundred is not too hide bound to perceive its utility. The locomotive engineer thinks a locomotive cannot run unless its cranks are at angles of 90°. He knows all about fly-wheels, but fly-wheels revolve round a centre, and he does not realise that a 60-ton locomotive moving at 60 miles' velocity in a straight line is as good a fly as a 60-ton wheel rim at 5,280 feet per minute circular velocity. There is really nothing special in Mr. Manson's engine. It's simply a partial step in the right direction, but has the mark of the conservative beast in the shape of cranks at 90°. Especially for long runs is this angle unnecessary. To this fetish locomotive men sacrifice speed, balance, bridges, rails, quiet, durability, rather than employ a little barring engine. To speak of blows like a sledge hammer being given to the rails is wrong. The effect of balance weights is simply to alternate lighter and heavier wheel pressure on the rail. The rail does not distinguish between a wheel of 10 tons pressure whether such pressure be simply normal or made up of 5 tons weight and 5 tons centrifugality. It has been known that the wheels of some locomotives with heavy counterbalances must, at high speeds, lift off the rails. An American college has a sample locomotive which has shown this experimentally by means of running it on friction wheels with lead wire between these and the engine wheels, the wire being flattened proportionately to the pressure. Large wheels with English design of moving parts appear not to cause trouble, the tendency to hammer blow being inversely as the wheel diameter squared, a 7-ft. wheel being thus barely half as bad as a 5-ft. wheel for equal forward travelling. With electricity there need be no imperfect balance; hence the wide range of wheel diameter possible.—EDS. ELEC. REV.]

Electrical Advertising.

Could you kindly inform me in your next issue if I should infringe anyone's patent by fixing glow lamps in front of

* For 7 feet wheels, as they are understood to be.

D

letters on a sign board, and switching the same by contacts, worked by any ordinary clock movement.

A. E. Rouch.

[We imagine one is at perfect liberty to do this, but perhaps some of our readers can give more precise information.—Eds. Elec. Rev.]

Electrical Hypothesis for the Solar and Planetary Systems, &c.

Only recently the Electrical Review was celebrating, with just pride, its attainment of years of discretion; or shall I say, of venerable antiquity? Should it not then be prepared to put away childish things, lest detractors should be tempted to speak of a second childhood having come upon its hoary hairs? Of course, those who can appreciate the intense humour of "Delta's" *Electrical Hypothesis for the Solar and Planetary Systems, &c.*, would not for a moment suspect the editor of the Review of mistaking the true value of such a contribution; but how about the large number of your readers, whose knowledge of physics is not much greater than "Delta's" own? May not they think that four and half columns of the leading electrical journal is enough to give an article the hall-mark of, if not authority, at least of some pretensions to sense. To criticise such a production adequately would be waste of your space; a writer who thinks that physicists of to-day regard the sun as being "in a state of magnificent conflagration," gradually "burning itself up," is hardly in a position to point out difficulties in their views.

It is a small matter that "Delta" regards the present estimate of the sun's distance to exceed 95,000,000 miles, but it shows his study of astronomy does not extend to very recent works; for the analysis of the results of the observations of the transit of Venus of *1874* brought the estimate down to its present figure of between 92 and 93 millions. But his ignorance of the absorption of radiant heat by the atmosphere, and his quaint idea that, according to existing theory, beams of light should "be seen traversing the dark interplanetary space, exactly as we see the beams of an arc light projected from the lantern of a lighthouse at sea," stamps "Delta" as a paradox-monger of the lowest order; even the paradoxer, however, should not draw so freely on his imagination as to say, we *know* "that if it were possible to produce an absolute vacuum between two separated terminals of opposite polarity, that an electric current would flow from one to the other, &c."

But, seriously, Sir, it is surely the duty of a paper of the Electrical Review's standing not to publish articles of this kind without a warning note that if not *written* for a joke, they are at least only printed for the amusement of your readers. It is difficult enough to drive sound science into the mind of the average individual, to the great cost of the nation in its commercial progress and struggle with competitors, but the technical press should at least be careful that it does not obscure the "dry light" of science.

Arnold G. Hansard.

Ipswich, Queensland.

On page 80 of your issue of January 21st, we notice that under the heading of Ipswich (Queensland) our name is included as having given tenders for Sections C and D.

Permit us to say that this is an error, as we do not quote for electrical apparatus, and Sections A and B were the only ones for which we tendered.

By making the above correction in your next issue, you will oblige.

Babcock & Wilcox, Ltd.
H. W. Kolle.

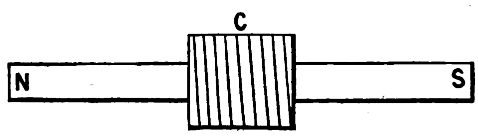
147, Queen Victoria Street, London.
January 24th, 1898.

[The table of tenders submitted, was given as stated last week, on the authority of the *Australian Building, Engineering, and Mining Journal*, which gave Messrs. Babcock & Wilcox's name in all the four items, together with the amounts quoted. We refer our correspondents to that journal.—Eds. Elec. Rev.]

A Problem.

The following problem might prove interesting to some of your readers:—

A helical coil (*c*) consisting of a single layer of insulated wire surrounds a bar magnet (N.S.)



How can the coil be taken away from the magnet without having an E.M.F. generated in it?

Archd. H. Finlay.

Electrical Engineering in the Colonies.

May I ask you to let me have a little information in one of your next numbers as to the prospects of a thorough practical electrical engineer in any of the Colonies, especially New Zealand, and oblige.

E. Smith.

[Perhaps some of our readers, with special experience in this direction, will be able to give some information.—Eds. Elec. Rev.]

"HONOUR TO WHOM HONOUR IS DUE."

There have been a good many misstatements made on the subject of wireless telegraphy, and most of our readers are aware that much annoyance has been felt in some quarters at the publicity which Marconi and his methods have obtained. We must confess to a feeling of surprise, however, that a science note in the *Pall Mall Gazette* should state that "It has been very vexatious for Dr. Lodge to have a young foreigner cutting from under his feet, the ground he had made so peculiarly his own, and to see his rival taken up by the British Post Office authorities." Why should Dr. Lodge be vexed at the cutting-out operations of Marconi? Did Dr. Lodge ever submit anything himself to the Post Office? From a scientific point of view Dr. Lodge ought to rejoice that his theories have received such striking confirmation, but we take it that the origin of the offence arises from the fact that the British Post Office investigated the system and apparatus brought forward by Mr. Marconi, who came here with proper credentials and introductions, and whose methods, after all, have, apparently, not commended themselves to the postal authorities. It seems to be forgotten too that Mr. Preece for 14 years past has been experimenting in this direction, and in 1895 secured practical success.

Nothing was said, nor, indeed, was much done, till it was discovered that the Post Office was making further experiments, and that there was a remote contingency of a new system of wireless telegraphy coming into actual use. Then, indeed, we find professors of the highest repute rushing into print, and using every opportunity to belittle the efforts of a young man who was merely attempting to demonstrate the commercial utility of a system that had been previously relegated to the lumber-room of a laboratory. We cannot help thinking such an attitude suggests little of the scientific spirit that pervaded such men as Faraday and Davy. There is an element of commercialism that we should scarcely expect to meet outside the City. Davy demonstrated the power of an electric current to effect chemical decomposition; moreover, by the agency of the electric current he succeeded in extracting potassium from potash, and thereby laid the foundations of an industry that has had untold influence upon the wealth of the country. But what was Davy's guerdon or reward? Faraday took Davy's electro-chemical work a step forward. More than all he discovered the first principles of the dynamo; but would Faraday have heaped abuse upon the men who, grasping the importance of his discovery, sought to utilise it in a practical way? We think not. Rather would he have rejoiced that the fruits of his mind had met with such striking appreciation.

Commercial electricity has done much we know to kill that kind of spirit, but still we should have thought that the dignity that even nowadays attaches to science, would have prevented the unseemly incidents that have marked the introduction of wireless telegraphy into this country.

THE ENGINEERS' STRIKE.

This we had hoped would have completely terminated before the opportunity of again using the above heading. But it seemed good to the strike leaders to withdraw the nominal basis of the quarrel, and to pretend to the continuance of the dispute on another basis, on the assumption of some fancied interference with the principles of trades unionism, a species of magniloquence now so common. A large display of verbiage is perhaps required to cover a few very awkward facts. A moderate estimate of expenditure and wages loss upon the strike is that the men's side have mulcted themselves to the extent of £3,000,000 sterling, which is a pretty big sum to pay for the privilege of butting one's head against a stone wall for six months, especially if it be thought that the destruction of the wall would drown one in the ditch beyond. But all this wall-butting has been done to please a section of the men's executive, and there is a disposition abroad to accept the intentions of this section as perfectly good, as founded on a belief that the results aimed at were such as could be commended. We confess never to have had this belief ourselves. We have not rated the intelligence of the men's executive at the level of their procedure, and have simply explained this procedure as dictated by personal motives alone, by a wicked desire to be unpleasant, irrespective of the consequences to either the enemy or to the deluded victims, the men themselves. When the *Engineer* considers it important that the wishes of Mr. Barnes and Mr. Sellicks should be known, we fail to see why. Could they have had their way, they would have had it even if they had wrecked the country in doing so. It is simply that they have a desire to get on in the world, and we recognise this desire as perfectly lawful to a point. Doubtless the idea was, once again, to squeeze employers, and rise a peg on the glory of having won a fight and paved the way for another. The suggested full management of the shops, and the action of the A.S.E. when they had got it, hardly comes into the scope of argument. The immediate question is what of the future. It is idle to blink the fact that the men are routed completely, and we know many of them are very sore. Can trades unionism be rehabilitated on respectable and sound lines? Is it absolutely necessary that the men's leaders should be men capable of stump oratory? We do not find that the managers of life insurance companies are speech makers, or even expected to be, yet in the case of the A.S.E. we find the huge funds of the biggest trades union placed unreservedly in the hands of a man whose title to run the business, seems to have been simply an ability to harangue the crowd.

When the 48 hours' demand was withdrawn, the employers offered to open their shops last Monday to the union men in their collective capacity, but this did not meet the men's approval, and the lock out notices pending were put in force. As a result of negotiation, however, the employers granted a week's extension of the time for returning to work, and by Sunday it was generally understood that next Monday will see a return to work. Fresh firms were posting lock-out notices up to the end of last week. The cause of the delay in returning to work seems to have been due to internal dissensions of unionism. The members in the country naturally feel they have been sold by the executive in London. They have fought for seven weary months the battle of the London men at the order of a London executive, on a point which is now dismissed as hardly worth consideration, and the men are now debarred from going back to work on a new issue altogether. All this, of course, raises into prominence the real issues, those of management and machine working.

As to the A.S.E., the general opinion is that this society is financially ruined, and a new society of 10,000 members is to be started on the Clyde. Probably the near future will see trades unionism more healthily managed, with self-contained local societies in place of one huge centralised body, of which the centre knows not the outlying districts except as contributors to the centre only. Local interests and general interests must be lost sight of when a trades union becomes a huge fighting machine. We should like to see not only trades unionism split up into local bodies, but also the Employers' Federation similarly reduced. It borders on the impracticable to deal with local interests by a centralised body. Far better work can be done by local societies with some touch of the humanities in them. Masters and men know each other; there is not the chance of working the amount of mischief that the present system allows the blatant self-seeking agitator.

In the old days of 25 years ago we recollect how the representative of the union in the workshop got along on friendly terms with both men and masters, and it would be so again were the irresponsible district general secretary unable to foment local quarrels on such questions as the opening of eggs at the large or small end. To run a huge affair like the A.S.E. successfully demands brains and intelligence and common sense. From the very beginning of the present strike, or from when its true basis was perceived, which was not long after it started, everyone seems to have arrived at the conclusion that the men would lose, yet the fight went on to the complete extinction of funds and into a great depth of debt. Why could not the men's executive see that they could not win and retire before the strike was a month old? John Burns said he would have it over in a fortnight. Why, if he could not win in a fortnight, did he not consent to be beaten? We think it well that the men's leaders have been afforded a glorious opportunity of demonstrating their intelligence and capacity to lead. With their fall comes the destruction of the false surroundings that have gathered upon trades unionism and choked its vitality, but the fall of trades unionism as practised by no means implies its extinction as an honourable institution when properly managed.

The morning papers of last Monday were able to announce that the strike was over, and that next Monday will see a general return to work. This will round up the duration to 30 weeks. To each clause of the employers' conditions there is now appended a note. We see very little in these notes, but it pleases Mr. Barnes to consider they modify the harshness of the clauses, and the men are ordered back to work. While, therefore, we are of opinion that the men have lost, as they deserved to do, we consider also that they will discover, before they can again afford to strike, that there are possibilities of high wages in British engineering that they have been for years striving to bury under a load of stupid restriction. That this may be found out by the men is much to be hoped, and this it is makes it so desirable for employers to keep to the front. True, they have had very little encouragement from their men these dozen years or more. Engineering has been a heart-breaking business with the half-hearted service and the rampant tyranny of trades unions; but we hope this is all over, and that work will now go on harmoniously, and we hope also all the men at present out will speedily be re-engaged, and find good wages. We reprint below the final clauses and notes of agreement. Resumption of work still awaits the return of the men's ballot which was to take place yesterday, but Mr. George Barnes, interviewed by a Press representative, stated that the men would have to accept the terms of settlement whether they liked them or not. Work would definitely be resumed on Monday next, 31st inst.

Thus, in this curt manner, does the men's general secretary treat the feelings of the 81,000 men who, whatever else may be said, have fought a plucky fight. Here are the final clauses:—

"General Principle of Freedom to Employers in the Management of their Works.

"The federated employers, while disavowing any intention of interfering with the proper functions of trade unions, will admit no interference with the management of their business, and reserve to themselves the right to introduce into any federated workshop, at the option of the employer concerned, any condition of labour under which any members of the trade unions here represented were working at the commencement of the dispute in any of the workshops of the federated employers; but, in the event of any trade union desiring to raise any question arising therefrom, a meeting can be arranged by application to the Secretary of the Employers' Local Association to discuss the matter. Nothing in the foregoing shall be construed as applying to the normal hours of work, or to general rises and falls of wages, or to rates of remuneration."

Note.—No new condition of labour is introduced or covered by this clause. It simply provides for equality of treatment between the unions and the Federation by reserving for all the members of all the trade unions, as well as for all the federated employers, the same liberty which many trade unionists and many employers have always had. Special provision is made in the clause and in subsequent "provisions for avoiding disputes" to secure to workmen, or their representatives, the right of bringing forward for discussion any grievance or supposed grievance.

"1.—Freedom of Employment.

"Every workman shall be free to belong to a trade union, or not, as he may think fit. Every employer shall be free to employ any man, whether he belong or not to a trade union. Every workman who elects to work in a federation workshop shall work peaceably and harmoniously with all fellow employés, whether he or they belong to a trade union or not. He shall also be free to leave such employment, but no collective action shall be taken until the matter has been dealt with under the provisions for avoiding disputes. The Federation do not advise their members to object to union workmen, or give preference to non-union workmen."

Note.—The right of a man to join a trade union if he pleases involves the right of a man to abstain from joining a trade union if he pleases. This claim merely protects both rights. The Federation sincerely hope that a better understanding will prevent any question of preference arising in the future, and advise the members not to object to union workmen.

"2.—Piecework.

"The right to work piecework at present exercised by many of the federated employers shall be extended to all members of the Federation and to all their union workmen. The prices to be paid for piecework shall be fixed by mutual arrangement between the employer and the workman or workmen who perform the work. The Federation will not countenance any piecework conditions which will not allow a workman of average efficiency to earn at least a wage at which he is rated. The Federation recommend that all wages and balances shall be paid through the office."

Note.—These are just the conditions that have been for long in force in various shops. Individual workmen are much benefited by piecework. A mutual arrangement as to piecework rates between employer and workman in no way interferes with the functions of the unions in arranging with their own members the rates and conditions under which they shall work.

"3.—Overtime.

"Terms of Recommendation Agreed to be made to Employers.

"When overtime is necessary, the federated employers recommend the following as a basis and guide:—That no man shall be required to work more than 40 hours' overtime in any four weeks after full shop hours have been worked, allowance being made for time lost through sickness or absence with leave. In the following cases overtime is not to be restricted, viz.:—Breakdowns in plant; general repairs, including ships; repairs or replace work, whether for the employer or his customers; and trial trips. It is mutually agreed that, in cases of urgency and emergency, restrictions shall not apply. This basis is to apply only to men of the trade unions who are represented at this Conference. All other existing restrictions as regards overtime are to be removed. It is understood that, if mutually satisfactory to the Local Association of Employers and the workmen concerned, existing practices regarding overtime may be continued."

Note.—These overtime conditions are precisely the conditions now in operation in various places, though in many federated workshops no limitation whatever exists at the present time. In many cases this will be the first attempt to regulate or prevent excess of overtime.

"4.—Rating of Workmen.

"Employers shall be free to employ workmen at rates of wages mutually satisfactory. They do not object to the unions or any other body of workmen in their collective capacity arranging amongst themselves rates of wages at which they will accept work, but, while admitting this position, they decline to enforce a rule of any society or an agreement between any society and its members. The unions will not interfere in any way with the wages of workmen outside their own unions. General alterations in the rate of wages in any district or districts will be negotiated between the Employers' Local Association and the local representatives of the trade unions or other bodies of workmen concerned."

Note.—Collective bargaining between the unions and the Employers' Associations is here made the subject of distinct agreement. The other clauses simply mean that as regards the wages to be paid there shall be (1) freedom to the employer; (2) freedom to the union workmen both individually and in their collective capacity —that is to say, collective bargaining in its true sense is fully preserved; and (3) freedom to non-unionists. These conditions are precisely those in operation at present on the North-east coast, the Clyde, and elsewhere, where for years past alterations of wages have been amicably arranged at joint meetings of employers and representatives of the trade unions.

"5.—Apprentices.

"There shall be no limitation of the number of apprentices."

Note.—This merely puts on record the existing practice, and is to prevent a repetition of misunderstandings which have arisen in some cases.

"6.—Selection, Training, and Employment of Operatives.

"Employers are responsible for the work turned out by their machine tools, and shall have full discretion to appoint the men they consider suitable to work them, and determine the conditions under which such machine tools shall be worked. The employers consider it their duty to encourage ability wherever they find it, and shall have the right to select, train, and employ those whom they consider best adapted to the various operations carried on in their workshops, and will pay them according to their ability as workmen."

Note.—There is no desire on the part of the Federation to create a specially favoured class of workmen.

"Provisions for Avoiding Disputes.

"With a view to avoid disputes in future, deputations of workmen will be received by their employers, by appointment, for mutual discussion of questions in the settlement of which both parties are directly concerned. In case of disagreement, the local associations of employers will negotiate with the local officials of the trade unions. In the event of any trade union desiring to raise any question with an employers' association, a meeting can be arranged by application to the secretary of the employers' local association to discuss the question. Failing settlement by the local association and the trade union of any question brought before them, the matter shall be forthwith referred to the executive board of the Federation and the central authority of the trade union; and pending the question being dealt with, there shall be no stoppage of work, either of a partial or a general character, but work shall proceed under the current conditions."

Note.—A grievance may be brought forward for discussion either by the workman individually concerned, or by him and his fellow workmen, or by the representatives of the union.

General Explanation.—In no instance do the federated employers propose conditions which are not at present being worked under by large numbers of the members of the Allied Trade Unions. The federated employers do not want to introduce any new or untried conditions of work, and they have no intention of reducing the rates of wages of skilled men. These conditions, with relative notes, are to be read and construed together.

The following is also to be read in to the terms, being part of letter handed to the delegates at the Hotel Metropole on January 21st:—

"The note appended to the recent explanations issued by the employers, disclaiming any intention of reducing the rates of wages of skilled men, applies to time wages and to piecework earnings. In the latter case there is no intention of interfering with the usual practice of making extra payment for extra effort."

The latest news to hand is that such ballots as have come in are in favour of a return to work on the above conditions.

Alternating Enclosed Arc Lamps.—The General Electric Company are, we understand, now in a position to supply a good enclosed arc lamp for alternating current circuits, taking 6 amperes.

Annual Dinners.—The annual dinner of Messrs. Rosling & Appleby, electrical engineers, of Bradford, took place at the County Restaurant on Friday evening, 21st inst., when about 100 sat down. A musical programme was afterwards executed.

The staff and long-service employés of the Electric Construction Company, Limited, sat down to the fourth annual dinner given by Sir Daniel Cooper, Bart., the chairman of the company, on 8th inst. There were 220 persons present.

Bankruptcy Proceedings.—At the London Bankruptcy Court last week William Alan Fraser, electrical engineer, Cecil Court, Charing Cross Road, applied for an order of discharge. According to the official receiver's report, the bankrupt failed last February with liabilities £904, and no realisable assets. He commenced business in partnership at 18, Cecil Court, in May, 1895, with a capital of £250, borrowed from his father. The trading resulting in a loss, the partner retired in the following August. The bankrupt opened a branch business at Guildford in November, 1895, but that proved unprofitable, and was discontinued in July, 1896. During the following month he abandoned the London business, which had been carried on at a loss throughout, sold off the stock, &c., for £60, and used the proceeds partly in paying debts and partly for personal expenses and subsistence. The offences reported were (1) insufficiency of assets to pay 10s. in the £ to the unsecured creditors, (2) imperfect books, and (3) trading with knowledge of insolvency. His Honour upheld the report, and imposed a suspension of two years.

The case of Messrs. Paterson & Cooper, electrical engineers, of the European Works, Pownal Road, Dalston, Princes Chambers, Victoria Street, Westminster, and Regent Street, Glasgow, came before Mr. Registrar Brougham last week at the London Bankruptcy Court. The failure occurred in August, 1896, the accounts showing total liabilities £19,514, and assets valued at sufficient to yield a surplus of over £7,000, after discharging all liabilities. An application for the discharge of the bankrupts has been lodged, and was in the list for hearing on the 21st inst. Mr. Muir Mackenzie, on behalf of the debtors, applied for a further adjournment, in order that the assets might be realised before the application was heard, as the decision of the Registrar would be affected by the result. By consent of the official receiver and all other parties interested, his Honour ordered the hearing to stand over until March 25th.

Business Announcement.—Mr. J. W. Westmoreland, F.I.C., who has been for the last five years an assistant analyst with Mr. Edward Riley, has opened a laboratory and assay office at 3, Love Lane, Eastcheap, E.C., and is prepared to undertake the sampling, assay, and analysis of ores, minerals, metals, and metallurgical products generally.

Catalogues.—The General Electric Company have issued the 12th edition of their electric bell catalogue, also the seventh edition of their telephone list. These two sections of the company's catalogue contain prices and particulars of all requisites for electric bells and telephones, and these editions are specially brought out to emphasise the fact that, as these are the two directions in which the hardware dealer or ironmonger usually starts when adding electrical work to his business, the company have kept the idea before them of making them as simple as possible, in order that a customer may find them sufficient to enable him to start in these lines. A full description is given of their new works at Manchester, where the supplies mentioned are made. In the electric bell catalogue many new developments are introduced. The bell and indicator pages have been very much enlarged, and many new patterns added. Batteries, bell pushes, wire, and all the various accessories are detailed. As in previous editions, a few notes are included on the application of electricity, instructions and diagrams, enabling customers to fit up any ordinary electric bell installation. At the company's Manchester works a very large extension has been made by the laying down of new and most efficient plant for the manufacture of telephone supplies, and it is considered that the telephone catalogue will show that in all branches of the telephone industry a very great advance has been made since the issue of the former edition. Special attention is directed to the general intercommunication telephone sets, and also to the fact that throughout the list the transmitter in use is the Hunningscone Deckert, which has done excellent service. Many new illustrations are in this section, showing the developments alluded to, and as in the case of the bell catalogue, the fitting of the various systems mentioned in the list is dealt with at the end by means of diagrams and descriptive letterpress.

Messrs. Cox-Walkers, of Darlington, send us a blotting square for the desk.

Ediswan's Employés.—The employés at the Ponder's End Works of the Edison and Swan United Electric Light Company, Limited, held their annual Christmas entertainment in the Queen's Hall, People's Palace, on Friday, January 21st. A special train was engaged, left in the afternoon carrying about 1,100 of the workpeople and their friends. The programme included dancing, Mr. Berry's Concert Party, and the Animated Photographs. The employés were admitted free to the East London Exhibition of Trades and Inventions, which adjoins the Queen's Hall.

Ediswan Lampholders.—The Ediswan Company are introducing the "Ediswan" enamelled liner, or "anti-shock" lampholder, which consists of the company's patent "S" insulator, the interior of which is surrounded by a patent enamelled liner, thus entirely preventing any possible contact with the outer case by means of stray ends of wire. The enamelled liner, as shown, is fitted inside the brass case in such a manner that it does not interfere with the present facility of wiring, &c., and the holder may be wired without removing the enamelled liner. The company's lampholder licenses expired yesterday, 27th inst., and the patent "S" holder can be manufactured only by this company, and supplied with or without the enamelled liner.

Experimental Research.—Messrs. F. Hutchins & Co., experimental engineers, 13, Victoria Street, Westminster, announce that they have lately taken new premises at Gray Street, Blackfriars, which are now fully equipped for carrying out experimental work. Besides workshops for the manufacture of technical apparatus and inventors' models of all kinds, they have private rooms which can be placed at the disposal of patentees and others, with engine power, use of tools and instruments, supply of electric current, &c. In connection with electro-chemical and other such work, when in the experimental stage, considerable expense has usually to be incurred in taking special premises and purchasing plant. We understand that special facilities are offered by Messrs. Hutchins & Co. for such work.

Granger's Steam Jet Blowers.—We have received from Mr. W. A. Granger, of Brooke Road, Stoke Newington, an illustrated list of his forced draught furnace, in which the advantages of forced draught are dilated upon, the Granger system described, its good points emphasised, and the saving effected by it mentioned. The statements are supported by results of tests made in every-day practice. A list is given of firms using the system. Another list issued by Mr. Granger gives particulars of his patent variable steam jet blowers. It is claimed that these can be very easily applied to Babcock boilers by placing them either through the back or sides of the ashpit, or under the floor level, so that the front of the boiler remains quite unaltered. We understand that the blowers are in use at large iron and steel works in the Glasgow, South Wales, and other districts, chiefly for blowing ingot furnaces and gas producers. They are also used at several electric light stations, including the Kensington and Knightsbridge works, where they are employed on the Babcock boilers at both Chapel Place and Kensington Court.

Liquidation Notices.—A petition by Henriette R. Gaulard, of 28, Canterbury Road, West Croydon, for the winding up of the National Company for the Distribution ot Electricity by Secondary Generators, Limited, is to be heard at the Law Courts before Mr. Justice Wright, on February 2nd.

A meeting of the Westralian Electric Lighting and Supply Company will be held at 54, Old Broad Street, London, on March 2nd, at 2 o'clock, for the purpose of hearing an account of the winding up from Mr. G. H. Homan, the liquidator.

Notching Armature Discs.—Messrs. Sponholz and Wrede, of Exercier Strasse, 6, Berlin, send us a list of their automatic machines for notching armature discs in dynamo machines and electro-motors.

Parliamentary Bills.—Among the Bills before the Examiners of Private Bills at the House of Commons on Monday that complied with the Standing Orders of Parliament were the Central Electric Supply Company (Powers and Works in Marylebone) and the General Power Distributing Company.

"Sell's Directory of Telegraphic Addresses."—Mr. Henry Sell has just published his well-known directory of telegraphic addresses, which is, as usual, compiled from official lists supplied by the Postmaster-General, and contains all the information received from the Post Office to January 1st, 1898. In addition to telegraphic addresses and telephone numbers, there is much useful data. Telephone and telegraph rates for all parts, both at home and abroad, are set out in handy tabular form. The details of charges for communication on the trunk lines constitute a good feature, and reductions in cable rates are also interesting. There are some general comments and statistics regarding British trade during the past year —a period of prosperity and conflict.

Standard Electric Company.—We are asked to state that on and after February 1st, 1898, the firm of Green & Treacher, established in 1888 for the supply of electrical sundries and as manufacturing electricians, will be conducted under the name of the Standard Electric Company, at 17, Garlick Hill and 191 & 192, Upper Thames Street, E.C.

Steam Mail Carts.—Messrs. Julius Harvey & Co., who have completed their first six weeks contract under the Postmaster-General for conveying mails by steam motor van from London to Redhill, have been asked by the authorities to make another contract for a further period, the trials having been very satisfactory.

"Stearn" Lamps.—The Zurich Incandescent Lamp Company, of Victoria Street, S.W., has issued a new list (January, 1898) of the "Stearn" high voltage lamps, which, we observe, are used by about a score of municipal and company electricity supply establishments in this country. The list is undoubtedly a work of art, the arrangements, illustrations, and printing being of the best. Many of the lamps are shown natural size, including the double carbon, double carbon with filaments in parallel planes, single filament, and high voltage types. Among others included in the list are fancy, changeable voltage, miniature, candle, and other lamps.

The National Company for the Distribution of Electricity by Secondary Generators v. Gibbs.—In the Chancery Division on Saturday, before Mr. Justice Stirling, the above action was mentioned upon a motion for judgment in default of defence. Mr. Gore Brown moved the motion on behalf of the company, and Mr. Rawdon, who had just been instructed on behalf of the representative of the defendant, urged that this matter should not be taken as a short cause, but should go into the general paper, and that he should have leave to defend. It was a case in which injustice would be done unless he had an opportunity of defending it. His client was a foreigner, and her only appearance had been under protest, and he (Mr. Rawdon) wished an opportunity to consider whether he should move to discharge the service of the writ. The lady was in Paris, and that day only had her solicitors here got the affidavit from her. Mr. Gore Brown said that the other side had already had plenty of time. This was a claim made by the company against two gentlemen who assigned certain patents, relating to electrical distribution, for £220,000, with a warranty that the patents were valid.

The price was to be £200,000 in shares, and £20,000 in cash, and the vendors undertook to establish their title to the patents, and transfer them to the company. But the patents had not been transferred, and had been found in great part to be invalid and void. The defendant, Ruell, was administratrix of one of the patentees, and a claim had been made for the assignment, and damages for breach of the agreement. The writ was issued on December 16th, 1896; leave to serve on Ruell was given on February 22nd, 1897, and she entered an appearance under protest on March 3rd. That was not a step in the action which would prevent anyone so appearing from moving within a reasonable time to have service of the writ set aside; but he submitted it must be done within a reasonable time, and here there had been 10 months delay. There had been litigation going on in France in connection with the same matter, and in 1894 the company obtained judgment entirely in their own favour, a decision which was affirmed on appeal, and there was really no ground for disputing the agreement. After some further argument, his lordship said that although there had been very great delay on the part of the defendant, still he thought it necessary, for her proper protection, to give her an opportunity further to consider her position. He accordingly directed that the motion should stand over until the first day on which he took non-witness actions.

The Ward Electrical Car Company, Limited.—Under the winding-up order recently made against this company, the statutory meetings of the creditors and shareholders were held on Wednesday, before Mr. Culley, Assistant Receiver, at the Board of Trade offices, Carey Street, Lincolns Inn Fields. The Chairman said the facts relating to the case were somewhat peculiar. The company was registered in October, 1888, with a capital of £300,000, and was apparently promoted by Mr. Ward, in conjunction with a Col. McMurdo, with a view to the acquisition of certain inventions relating to electricity and belonging to Mr. Ward, also to carrying on the business of electrical engineers. The whole of the capital—except the signatories shares—was issued to Mr. Ward on return for his inventions, and he was also to act as managing director at £1,000 a year, payable only out of profits, or until the formation of a subsidiary company. The whole of the shares having been issued to the vendor. The company had no working capital, but Mr. Ward entered into an agreement with Col. McMurdo for the sale to the latter of 22,500 shares for £10,000 payable as to £1,000 to Mr. Ward, and £9,000 to the company. Col. McMurdo died in May, 1889, having paid £4,362 on account. Mr. Ward then entered into an agreement with the Receiver of his estate, under which 20,000 shares were to be returned to him, and he was to provide the company with £5,000 for working capital. Mr. Ward further undertook to pay the company's liabilities until December, 1890. The money received by the company was used in developing the patents, but apparently without any definite results, and the only property acquired was stated to be a small amount of plant that had been seized by the landlord for rent, and an omnibus which had been seized under a judgment. The directors in April, 1896, authorised Mr. Ward to sell the whole undertaking to a new company for £35,000, payable as to £5,000 in cash, and the remainder in shares. That scheme was not carried through, but subsequently Mr. Ward, and a Mr. Marshall, floated the London Electrical Omnibus Company, Limited, to acquire other inventions belonging to the former gentleman. The purchase price was £20,000 cash, and £80,000 in shares, and was to be divided between the two promoters. Under the agreement with the first company, it was provided that all inventions and improvements thereon, sold to that company, should become its property. The inventions sold to the second company were stated to be improvements on the original inventions, so that a question of title would doubtless arise between the two companies. Mr. Ward had stated his intentions of handing over his shares in the new company for the benefit of the old company, and Mr. Marshall was now bankrupt in the London Court. The directors in August, 1892, resolved to issue debentures to a certain firm, and although there had been no actual issue, a claim to some of the company's property had been maintained with success. The original patents had apparently lapsed, with the result that the only asset belonging to this company was its interest in the London Electrical Omnibus Company, Limited. Accounts had been prepared showing unsecured debts, £863; fully-secured debts, £2,435; and assets, £1 9s. 1d. Mr. Ward intimated that he desired to present the shareholders with shares in the London Electrical Omnibus Company, Limited, which was now in a position to make a considerable profit by running electrical omnibuses. He had no doubt but that the old shareholders would consent to such an arrangement, as the shares would be of considerable value. The matter was left in the hands of the Official Receiver, to be dealt with in the usual manner.

The Year 1897.—Messrs. Drake & Gorham inform us that 1897 fully answered their expectations. The number of installations in country houses completed during the 12 months continues to increase, and twice during the year the firm has engaged new suites of offices. Amongst the country house installations may be mentioned the lighting of Rolleston Hall, for the Right Hon. Lord Churchill, with two large oil engines, and upwards of 300 lights; Brook House, for Mrs. Stephenson Clarke, with two steam engines and 420 lights; Tal-y-Garn, for Mr. Godfrey Clark, with two oil engines and 365 lights. The long list of installations also includes several hundred lights for the Marquis of Lansdowne; the lighting of Dr. Conan Doyle's house; also that of Mr. W. J. Crossley, of Crossley Bros.; Oulton Park for Sir Philip Egerton, &c. One of the largest isolated installations in the kingdom has been put down for the Prudential Assurance, and consists of a generating plant for 6,500 lamps of 16-C.P. An installation of 2,500 lamps, and a number of Jandus lamps, has just been completed for the Auxiliary Army and Navy Stores. The firm's Manchester branch have completed a number of installations in private houses, mills, and public buildings, amongst which may be mentioned the Linotype Company's new works, where 254 "Jandus" arc lamps, as well as 240 incandescent lamps, have been placed. The progress of the "Jandus" lamp, for which the firm are the sole selling agents, has been phenomenal, and a special department has been found necessary to cope with this rapidly extending business. The firm have developed a system of iron conduits, with a patented form of joint, which avoids all screwing, and consequently effects a considerable saving in labour.

ELECTRIC LIGHTING NOTES.

Aberdeen.—Councillor Johnson recently undertook to consult Prof. Kennedy on the question of utilising the dust of the city in producing electricity.

Bath.—Mr. G. F. Metzger has now been officially appointed by the urban sanitary authority as engineer and manager of the electric light works, to carry out the same duties as he has heretofore performed, at a fixed inclusive salary of £500 per annum, and two-thirds of apprentices' premiums.

Bristol.—The electrical engineer, Mr. Faraday Proctor, is to report on the cost of placing the electric light in a Cabot tower which is now being erected.

Bromley.—The Board of Trade have provisionally agreed to transfer the electric lighting order, but after a long discussion the District Council have postponed the question pending information as to the status of the company.

Cardiff.—The Electrical Engineer (Mr. Appelbee) reports that the total number of 8-C.P. lamps supplied on December 31st last was 15,431, compared with 14,136 in the corresponding period of 1896, an increase of 1,298. The lamps connected and applications received during December were 208, and the total number of lamps awaiting connection at the end of the month was 1,296. The number of units generated during December was 63,783, compared with 59,365 in the corresponding period of 1896, an increase of 4,418. The calculated revenue for last month was £78 from arc lamps, and £786 from private supply; total, £864. The revenue in December, 1896, was £819 19s. 1d. The lamp connections were less than could be wished, but the department was hampered for want of plant. The sale of current for the year 1896 was 308,430 units, compared with 342,461 units in 1897, an increase in the latter year of 34,031. The rates now charged were 6d. for the first two hours and 3½d. afterwards. He suggested that the rates should be 7d. for the first hour and 3½d. afterwards.

Chester.—A feeder is to be laid to increase the pressure for the light in Brook Street, Foregate Street, and other thoroughfares, at an estimated cost of £2,050. Councillor Roberts stated at the last Council meeting that the Electric Lighting Committee's expenses had been about £2,400, and their receipts had been close upon £5,000. The winter quarter ending December had realised close upon £1,800. They were told by Mr. Thursfield, who had had the management of the works as Messrs. Parker's representative, that they might look forward to a gross income next year of about £8,000. Notice has been given to Messrs. Parker that the Corporation intend to take over the works at the end of March. The sub-committee were going to recommend that the price during the current year should be 5d. instead of 6d. per unit. Two consumers of 2,000 units had received discount, enabling them to have the light at the net price of 4½d. per unit.

Dingwall.—The Town Council last week discussed the terms of a proposed agreement with the company which intends electrically lighting the district.

Douglas.—The Lighting Committee has considered tenders of the Douglas Gaslight Company and the Isle of Man Tramways and Electric Power Company to light the town respectively by gas and electricity, and has decided to recommend the acceptance of the Gaslight Company's tender, with power to terminate the agreement at any time so far as the sea front is concerned. The Gaslight Company offered to light the town with Welsbach burners at various prices per burner, while the Tramways Company offered to supply the current only for electric lighting at 3½d. per Board of Trade unit.

Dublin.—A member of the Dublin Mercantile Association complains that he has been waiting for a supply of current for about two years, and has not yet been supplied, although, he says, the mains come right up to his shop. He has been informed that the Corporation has not current to supply him with, and somehow or other from this he reasons out that the electric lighting powers should be handed over to the Electric Tramway Company, whose scheme is before the Corporation. The Dublin Mercantile Association consider that the rates now charged are excessive, and that if if the Corporation cannot improve the service, they should invite others to submit schemes.

Edinburgh.—The Lighting Committee recommends the lighting by electricity of various roads with 16, 13, 10, 16, 7, 12 and 16 lamps respectively. The proposal is that the lamps should be lighted at the rate of £15 per annum.

Elland.—The District Council has decided to ask the electrical engineer of Nelson to visit Elland, and make a report as to the character of the installation suitable for the needs of the town.

Finchley.—The Municipal Electric Supply Company has submitted terms of a proposal to light East Finchley with electricity. These have been sent to a committee for consideration.

Folkestone.—Plans of the electricity works have been prepared, and building operations are to be commenced at once.

Fort William.—The charges for current here to ordinary consumers are 9d. per unit from one hour before sunset till 9 p.m., and from 9 p.m., to one hour before sunset the following day 4½d. per unit. In the case of workmen's houses, there is a fixed rate of 10s. per 16-C.P. lamp per annum. The town is lit for the same price as was paid for gas, but instead of 58 gas jets there are six arc lights of 1,000-C.P. each, and 58 16-C.P. lamps. When the town was lit by gas there was the additional cost for lamp lighting, while this is now done from the central station. Three thousand lamps are now being supplied, but the plant has double that capacity.

Glasgow.—Mr. Chamen, the newly-appointed Corporation electrical engineer, will take up his duties from to-day. The Electricity Committee will now proceed with the arrangements necessary for the erection of the new works.

The Corporation has decided to supply the stanceholders in the Dead Meat and Fish Markets with the necessary current for lighting purposes.

Hampstead.—The Vestry has advanced Mr. Cottam's salary from £400 to £450 per annum. The chief assistant engineer has an increase from £200 to £225, and three assistant engineers are to advance from £117 to £130 each.

Hanley.—The Council's charge for electric current for motive power purposes is to be reduced from 3d. to 2½d.

Heavitree.—The Surveyor is shortly to report as to his inquiries *re* electric lighting.

Hornsey.—The Hornsey Gas Company and the Great Northern Railway Company threaten to oppose the municipal electric lighting scheme.

Horsham.—The District Council will spend £20 in obtaining information as to the cost of electric lighting for the district.

Huddersfield.—The borough electrical engineer, Mr. A. B. Mountain, has reported that the number of consumers is now 598, an increase of 30 over the number recorded in December. The lamps connected in the present month were 41,702, and in December 39,977—an increase of 1,725. The Empire Theatre, Huddersfield, is to be electrically lighted, and the management asked for the same rate of charges as were made for lighting the Theatre Royal. Tenders for the extension of the electric lighting station have been accepted. The extension is absolutely necessary in view of the increase of the business.

Islington.—The Vestry decided last week to lay a new cable and conduits from the works through Wellington Street to St. James's Road, and along one side of Liverpool Road to Upper Street, the total cost being estimated by the engineer at £3,164. The arc lighting is also to be extended through Liverpool Road, at a cost of £2,500, including about 40 arc lamps. Application is to be made to the London County Council for sanction to the borrowing of the necessary amounts.

Kingston.—Councillor Collings, chairman of the Lighting Committee, reports that for the past year the electric lighting revenue has been £3,889 17s. 6d., or £193 13s. 10d. less than they anticipated; whilst, on the other side, the cost of their works was £3,061 0s. 9d., or some £148 7s. 6d. below what they anticipated. They really anticipated a balance to the bad of £814 9s., and they found that the actual balance was £835 10s. 11d. The electric lighting undertaking had now reached another stage. Last year he reported that they were able to meet their works' cost, and he was able now to say that they could meet the interest on the principal.

Leicester.—The Gas and Electric Lighting Committee reports that the total output of current from the central station for the half-year ended December 31st last was 204,084 units. There were 350 consumers.

Liverpool.—The electrical engineer reports that up to December 31st the equivalent number of 16-C.P. lamps connected to the supply mains was, for private lighting, 60,690, and Corporation lighting 6,971, making a total of 67,661, being an increase of 2,706 for the month. The number of units supplied during December was, to private consumers, 300,658, and for the Corporation 64,455, making a total of 365,115, against 257,700 for the corresponding period of 1896.

Morecambe.—An arbitration took place on 24th inst. at Morecambe Council Office with respect to matters in dispute between the Council and the Old Electric Light and Power Company, Limited, on the former taking over the latter company's undertaking. The respective arbitrators were Mr. Thursfield, city electrical engineer, Chester, and Mr. Gibbings, city electrical engineer, Bradford. The principal point at issue was that the District Council agreed to give £3,897 for the Electric Light and Power Company's undertaking, and portion of plant, main cables and fittings, and a deed executed in February, 1896, contained a covenant stipulating that until the Local Government Board and the Board of Trade's sanction were obtained, and the undertaking formally taken over, the company were to keep the plant in the same state of repair as at the original valuation. The Council now alleged that the plant had deteriorated in value through being improperly stored, and the main cables not properly looked after, the latter being stated to be now useless for the Council's system, and worth £2,000 less than at the time of the valuation. In support of this contention, Mr. Parkinson, resident engineer, gave evidence as to recent tests, and was corroborated by Mr. Woodson, electrical engineer, Lancaster Waggon Works; Mr. Hedgecock, of the British Insulated Wire Company; and Mr. Burton, of Messrs. Callender & Co., London. The Chairman and Surveyor also spoke to the unsuitable place in which the stores were kept. On the other side it was contended that the mains were practically as good as when originally valued, except for 10 per cent. allowance for depreciation. On behalf of the company, Mr. Olirehugh, consulting engineer, Manchester, and Mr. Davidson, from Messrs. Glover & Co., Salford, who supplied the original cables, were called (says the *Leeds Mercury*) to show that the Council's tests were not taken under favourable circumstances, witnesses' tests giving 4,000 million ohms, as against 45,000 ohms by Mr. Parkinson. It was further contended that the cables could be put right for £50. The proceedings lasted several hours, and at the close the arbitrators intimated they would personally test the mains. At a recent Council meeting Mr. Parkinson, electrical engineer, submitted an amended plan, showing the positions of the arc lamps for public lighting. This was approved. It was resolved that, if possible, without interference with the terms of the present contract with Mr. Krauss, an arrangement be made with him and Messrs. Thomas Parker, Limited, with reference to laying arc light cables and erecting pillars on the promenade from East View to Bare.

Penarth.—The solicitors of the Electric Lighting Company have replied to the Cardiff Parliamentary Committee, stating that there is nothing substantial in the objections put forward to the electric lighting scheme.

Shanghai.—Arrangements were recently made for the electric lighting of Shanghai native city. Preliminary work was to commence in December.

Shoreditch.—The Vestry has been considering a scheme for heating the baths and wash-houses, so as to utilise in the most economical manner the steam supplied from the electric lighting and dust destructor engines. Messrs. Berry & Sons have quoted £4,695 as the cost of the necessary condensers and plant for the purpose. Mr. Henry Ward, C.E., has been appointed consulting engineer, at 5 per cent., to advise the Vestry in the matter, and to supervise the carrying out of the works.

Sittingbourne.—The new Sittingbourne waterworks have been lighted with electricity.

Southend-on-Sea.—Applications for the post of electrical engineer to prepare plans, &c., and supervise the construction of electricity works, have to be lodged with the Town Clerk by February 22nd.

Southport.—The electric lighting extensions have been completed, and the plant now installed has a capacity over five times as great as the original installation of 1893. The last addition includes an "ironclad" dynamo, driven by a 500 H.P. steam-engine, with a capacity of 10,000 lamps, bringing up the total capacity of the plant installed to 22,750 8-C.P. lamps.

St. Pancras.—At the Vestry meeting on 19th inst. Mr. Menzies, Chairman of the Electricity Committee, presented a report with plans and estimated cost of carrying out certain large extensions at the Stanhope Street, Regent's Park, generating station, in order to meet the continuously increasing demand for current. The scheme submitted provides for the erection of a new chimney shaft and buildings, including an additional boiler house, heightening and widening a portion of the engine room, so as to accommodate four 750-H.P. engines. It also provides for general stores, time, storekeeper's, and weigh-offices at the entrance to the yard, battery room over boiler house, condensing plant over engine room, with air pumps on engine room floor, boilers, lock-up coal bunkers under elevated roadway, ash elevator, and other minor accessories. It was unnecessary to instal the whole of the plant in the new buildings at the outset. A proportion only will be required, viz.:—Two 750-H.P. engines and dynamos, the bank of four boilers shown on plan, boiler feed pumps, feed-water heaters, a proportion of the condensing plant, switchboards, overhead travelling crane, ash elevator, lock-up coal bunkers, &c. The new chimney shaft would be some 200 feet high, 8 feet 6 inches internal diameter, and so designed as to accommodate all possible extensions on the present site. Mr. Sydney Baynes, chief electrical engineer, who had prepared the scheme, estimated that the capital expenditure on the portion of the building and plant, completed by the end of the present year, would be about £21,440. That sum included the cost of the chimney and flues, and represented the amount payable to the contractors, inclusive of £9,440, which would be due for the engines already ordered, and the whole completed scheme would involve a capital expenditure of £26,439, which the Vestry was now invited to sanction. Mr. Menzies, in moving that tenders be invited for carrying out the work, said they found as long ago as last March that all their plant and machinery was fully employed, and, therefore, they thought it was time to consider what they were going to do in 1898. They found from experience that it was necessary to order their machinery from 10 to 18 months ahead, and in order to cope with their enormously growing business they must get to work in time. A question to which the committee had given all the consideration in their power, was whether they could utilise the existing station in Stanhope Street for the proposed extensions, or whether they would erect a new and a third station. In the result they had decided on the former course on the ground of economy. Their business in 1897 had increased by 25 per cent. per annum, and at the present moment their plant was so heavily engaged, that it was doubtful the preceding night if they could spare sufficient machinery to try the new street lamps which had recently been erected; and further, it was now a question whether for some time they could accept any new customers. The Vestry had given them two dynamos, but they wanted boilers and housing for the dynamos, and when these were at work the capacity of the station would be doubled, and being capable of turning out 2,500,000 units of electricity a year, would be in a position superior to that of any London electrical station. There were indications that the time had arrived when they should provide for the future. If Mr. Maxim perfected his new incandescent lamp, it would mean that the people would have no more to pay for electricity than gas, and as through many channels they had enormous demand coming upon them, the committee, so as to be ready for any emergency, asked the Vestry to sanction this outlay, and thus be prepared for any demand which might arise during the next three or four years. Mr. Close seconded the motion, which was carried. Mr. Gardner did not object to the extension of the electric light, but he did not think it was a favourable time to ask for more money when the Electricity Committee owed its bankers £26,922 17s. 2d. for the Regent's Park station and £21,711 in connection with the King's Road station.

The L.C.C. Scheme.—The Highways Committee on Tuesday recommended the Council to invite, by public advertisement, tenders for the plant required for lighting the Embankment and Westminster Bridge by electricity. The scheme contemplates the provision of 144 arc lamps. It is suggested that they be distributed as follows:—28 along the kerb on the north side of the Embankment, 29 along the kerb on the river side, 64 along the parapet wall, five on the adjacent piers, eight in Northumberland Avenue approach, and 10 on Westminster Bridge and its approaches. Waterloo Bridge would be lighted free of charge by the Charing Cross and Strand Electricity Suppy Company, in consideration for permission to lay their mains across. The capital expenditure of the scheme is estimated at £25,300, and the annual maintenance cost at £3,509. The matter stands over until next week.

Torquay.—The opening of the electric lighting works has been postponed for another fortnight.

Treeton.—Subject to the approval of the Local Government Board, £140 is to be borrowed for completing the street lighting electric installation.

Turkey.—A Turkish paper just to hand announces that all the military barracks in Constantinople and the provinces are about to be fitted up for electric lighting, and that the necessary apparatus has been manufactured in the electrical department at the Admiralty in the Turkish capital.

Wallingford.—The electric light has been installed at the Wallingford Works of Messrs. Wilder Bros.

Weston-super-Mare.—In connection with the steps being taken by the District Council, for putting down a municipal electric lighting plant, the ratepayers have met together, and passed a resolution against the municipal proposal. They are in favour of a company taking the risk, and they recommend this course. A syndicate is at hand ready to pay all out-of-pocket expenses so far, if the Council will agree.

Wrexham.—The Local Government Board does not approve of the Council's proposal to purchase the Willow Brewery premises for £8,000, for the purpose of converting them into an electric light station, gymnasium, baths, &c. If the Corporation still desire to buy the property, the Public Works Loan Commissioners will be recommended to lend the necessary money.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

Belgium.—La Société des Tramway Electriques de Gand is the title of a company which has just been formed in Ghent to acquire the horse tramway in that town owned by the Société des Railways Economiques de Liége-Seraing and the Compagnie des Railways à Voie Etroite, and to convert the same into electric lines. The capital of the company is £140,000.

Birmingham.—According to a Birmingham paper it seems that the negotiations between the Tramway Company and the City Corporation, which were broken off about a year ago chiefly on account of the objection raised by the Corporation to the overhead trolley on the recommendation of its Continental deputation, are about to be resumed. Mr. Ross is shortly to return to Birmingham. The *Daily Argus* in a recent article on the position says that the lapse of time has not improved the position of the company or contributed to an amicable settlement. To begin with the holders of the present lines are one year nearer the termination of the lease. Consequently, whatever necessity existed 12 months ago for an extension of time to replace the capital outlay is more urgent now. "But, on the other hand, the feeling against the extension of the lease is stronger than at that time. Those most completely in touch with the Council, and particularly the department charged with the task of negotiating with the City Council, assure us that members who, 12 months ago, shrank from so serious an addition to municipal responsibilities as the control of a tramway now admit that this course appears to be the only way out of a difficult situation. The force of the company's contention that the 21 years' lease inevitably entails a loss upon those who lay down an underground conduit is generally recognised. But the determination to resist the overhead system is stronger than ever."

Bradford and Leeds.—The promoters of this Light Electric Railway (Power and Traction, Limited; W. N. Stewart and R. A. Smith, M.I.E.E., managing directors) have been circulating a pamphlet respecting the proposed line and its good effects upon the districts touched by it.

Brentford.—The District Council has been considering the proposed trolley electric tramway scheme, which would touch this district, and seems favourably disposed toward the undertaking.

Bristol.—The Bristol Tramway Company are promoting legislation for the use of electricity on all their lines, and for the construction of new lines in several parts of Bristol, and this matter having been referred to at a meeting of the Bristol Sanitary Authority, the Town Clerk stated that the question arose whether the company had complied with standing orders as to the deposit of plans, and he had therefore laid a memorial before the Examiner of Standing Orders, complaining of non-compliance. The Committee approved of this course. The matter came before the Examiner on Friday, when the Corporation of Bristol was represented by Messrs. Dyson & Co., Parliamentary agents, instructed by the Town Clerk. Mr. Warwick Webb, Parliamentary agent, instructed by Mr. H. G. Doggett (Bristol), represented the company, on behalf of whom Mr. Sam. White (secretary), and Mr. Edwards (resident engineer), was also present. On behalf of the Corporation it was alleged that there were defects in notices, bills and plans, but after hearing all the arguments the Examiner decided in favour of the Tramway Company on all points. One of the allegations made by the Corporation was that proper notice had not been given of the proposal of the company to make their horse tramway an electrical tramway. It was a work of so much importance that proper notice ought to have been given. It would necessitate the breaking up of 11½ miles of the city streets. Mr. Faraday Proctor, electrical engineer to the Corporation, was called and said that under the Bill it would be necessary to take up the whole of the road bed for the entire width of the road, and perhaps 18 inches or 2 feet on either side, and to a depth exceeding a foot, in order to put down a concrete bed. At present the rails were on chairs, and these chairs rested upon blocks of concrete, but the rails in the spaces between the chairs merely rested on the road. It was proposed in the Bill to make a continuous bed of concrete along the whole length of the line.

Charing Cross and Paddington Bill "dead."—The Bill for powers to construct, at a cost of £1,225,734, an electric underground railway connecting Charing Cross, *viâ* Knightsbridge, with Paddington terminus, was officially marked "dead" at the Houses of Parliament last Friday, there being no appearance of the promoters when the Bill was called by the Examiner on Standing Orders.

Electric Tramway to the Alexandra Palace.—Preparations at the Alexandra Palace are going on apace. Spaces for industrial exhibits are nearly all let. The necessary repairs are well ahead. Arrangements have been completed to run an electric tramway from the Wood Green entrance up to the top of the hill for the benefit of residents in the Wood Green locality.

Finchley.—The Hampstead Vestry will oppose the scheme as set out in the Finchley, Hendon, and District Light Railways (Electric) Bill. The Finchley District Council has submitted its list of objections to the scheme.

France.—The construction of the new electric tramways in the town of Elbeuf (Seine Inferièure) is approaching completion. The plant at the power station comprises three Garnier steam engines and three Postel-Vinay 100-kilowatt dynamos.

Glasgow.—The German firm is reported to have given up the contract for tramway rails. A sub-committee is now to accept the tender of a Leeds firm, subject to the adjustment of certain details. The amount of this estimate—the only British competitor for the contract—is said to be £1,700 in advance of the German offer.

Hanley.—The Council has resolved "That a conference be arranged with the local authorities in the Potteries and Newcastle with a view of considering the advisability of proceeding unitedly for the purpose of acquiring and working the tramways and extending the same, and that subject to certain specified restrictions, the consent of the Council should be given to the application of the North Staffordshire Tramways Company for a provisional order to lay down further lines within the borough."

Kidderminster-Stourport.—A provincial paper says that it is expected that this line will be completed by about the end of February.

Kirkcaldy.—Prof. Kennedy had a meeting last week with the Tramways and Town Council Committees with a view to reporting on the proposed combined electric lighting and traction scheme. Prof. Kennedy recommended the combined scheme, which had no engineering difficulties, and was being carried out in other towns, and he approved of the overhead electric system of traction.

(*Continued on page* 117.)

THE MANUFACTURE OF TUDOR ACCUMULATORS.

It is hardly necessary to say that the Tudor accumulator had established a splendid reputation on the Continent long before it was introduced into this country. In the most striking developments in electric traction—we refer to the combined trolley and accumulator systems—the Tudor accumulator has been intimately associated, and when we say that the Hanover tramway system and the Zurich tramway rely for their efficient working on this type of accumulator, we are merely stating in another way that it has achieved the distinction of showing that the storage battery is not an impossible factor in tramway traction.

The Tudor accumulator is by no means due to an inventor's lucky inspiration. It has been slowly evolved from the results of protracted experiments and ceaseless observations. Mr. Tudor, who curiously enough is an Englishman, has been for many years developing the type of accumulator that we now associate with his name, and how great a commercial feature the Tudor accumulator is on the Continent, may be gathered from the fact that at Hagen alone there are 800 workpeople engaged upon its manufacture.

Some three or four years ago the Tudor accumulator was brought to this country by Mr. A. B. Pescatore, and the manufacture of it was commenced at Dukinfield, near Manchester, some time afterwards.

We have recently, through the courtesy of Mr. Pescatore, had an opportunity of witnessing the various operations that are carried on in the works at Dukinfield, and by means of the illustrations and notes we trust to be able to reproduce some of the impressions we received.

It is generally well known that the positive plates of the Tudor cells, which are perhaps the most distinctive features of these accumulators, are lead plates of large surface, and are formed on the Planté method. The large surface is due to the peculiar form in which they are cast. The plates are formed by a process very similar to the one originally devised by M. Gaston Planté, modified only so far as to ensure greater adherence and homogeneity, and to obtain greater rapidity in formation, without the use of corrosive acids, such as were employed by M. Planté in his later processes.

The first striking feature in a survey of the Dukinfield Works is the casting shop, in which there are two large melting pots, each capable of holding about two tons of lead. The one pot contains pure lead, from which the positives and most of the negatives are made.

The second pot contains an alloy of lead with a small quantity of antimony, which is used for certain small accessories and for the large type of negatives such as those in the Glasgow batteries referred to later on.

Although the casting shop is a difficult one to show by photography, the illustration gives a fair idea of its arrangements. In the construction of the Tudor cells, the manufacturers attach considerable importance to what appears to us a vital point, namely, the purity of the lead used in the plates. Indeed, we believe the makers are modest enough to affirm that much of the success achieved by the accumulator is due to this fact. However that may be, they certainly insist upon obtaining the best brands which can be guaranteed to contain less than 0·1 per cent. of impurities.

Plumbers' Shop.

The moulds in which the plates are cast are in two halves, each corresponding to one side of the plate, and consisting of a rectangular cast-iron frame, in which are held a number of gun-metal racks, 15 mm. wide, cut with very fine teeth. A very slight space is left between each rack, corresponding to a horizontal rib on the plate; at intervals of about 120 mm., a tooth is cut away on each rack, so as to give an extra strong vertical rib at those points. These vertical and horizontal ribs and the strengthened edges, while giving greater rigidity to the plates, provide paths for the current, of which they thoroughly ensure the even distribution. Slots are cut in the cast-iron frame, so that the lugs and strengthening edges are cast in one piece with the rest of the plate.

The two halves of the mould are mounted in a vice, one side of which is fixed, the other being movable, first for an inch in a direction parallel to itself, and then about an axis, so as to entirely open the mould for the removal of the plate. In the positive plate, when the mould is closed, the apexes of the teeth do not touch, and a thin backing is formed; the pitch of the teeth being about 2½ mm. and their depth 6 mm. In the moulds for the negative plates, which consist of an open grid, the teeth on either side touch when the mould is closed, and the thickness of the teeth on the racks is much greater.

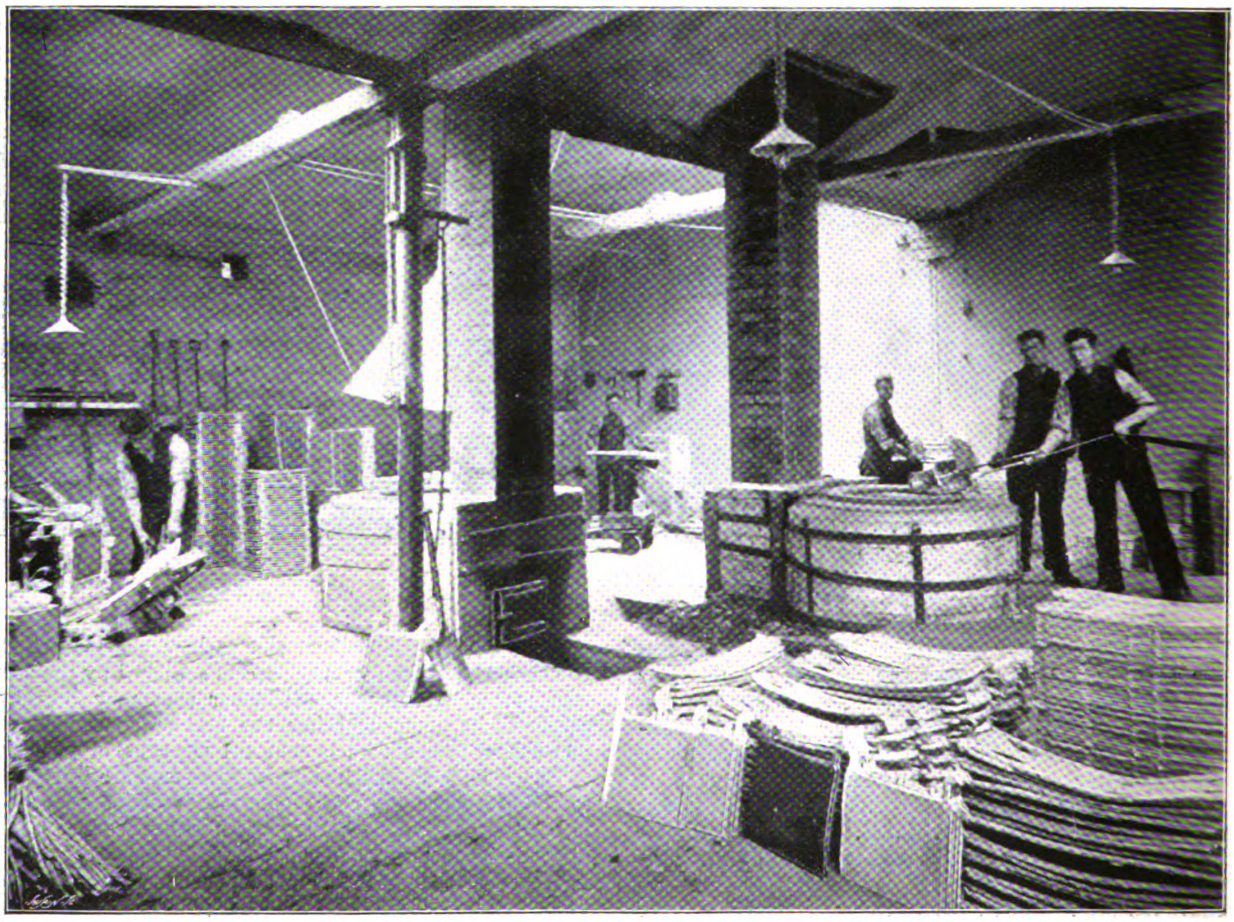
It is, of course, of the utmost importance that the teeth should be cut with great accuracy, and they are made as rectangular as possible, to avoid sharp edges on the surface of the plate, which would rapidly become worn out. Great care has therefore been bestowed upon the design and workmanship of the moulds, and the cost of them is very considerable.

For the purpose of forming the positive plates, they are brought into the formation rooms, a view of which is given, where they are mounted in lead-lined wooden boxes. The plates are hung from glass sheets, and are burnt to temporary lead connecting bars, in much the same way as they are usually mounted in Tudor cells. The plates, both positive and negative, are of the positive large surface type, the cells being filled with dilute sulphuric acid only. The peroxide of lead on the surface of the plates is produced first by alternately charging the cells and leaving them on open circuit, and afterwards by alternately charging and discharging them at frequent intervals throughout the day, the discharge becoming heavier as the formation advances. Finally the cells are charged and discharged under the ordinary conditions, until they attain very nearly the normal capacity, when the plates that have been used as positives in the formation are removed and dried.

Filling Paste in Negative Plates.

The formation period lasts about six weeks, and is carried out as continuously as possible, day and night. There are at present in use about 300 boxes, each containing 21 or 42 plates, according to the type.

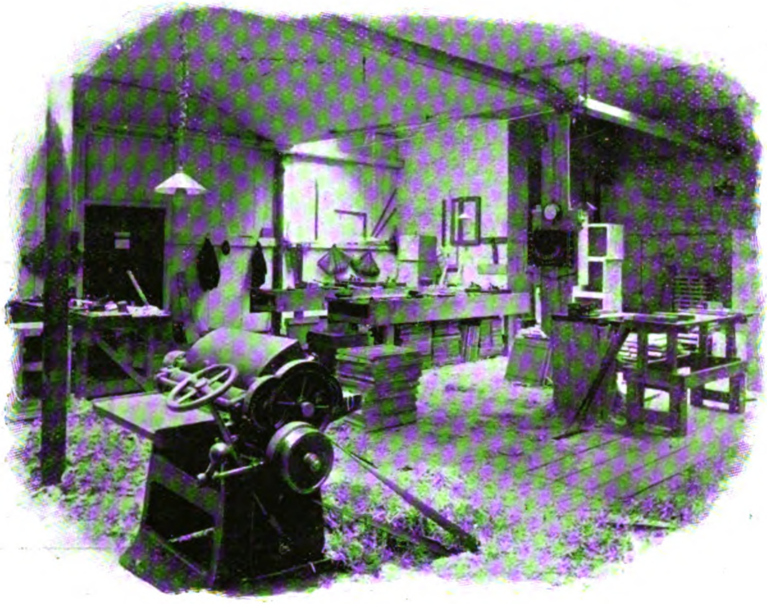
To prepare the negative plates, the grids are first "pickled" by charging them positive with a heavy current for a few seconds. They are then filled in the ordinary way with litharge, formed into a paste with sulphuric acid. The operation of filling in the litharge is shown in one of the illustrations. After being dried, the majority of negative plates are sent out without any further preparation. It has been found that the active material of the negative plates, which is lead in an extremely fine and divided state, oxidises and sulphates so readily, that the time required for reducing



Casting Shed.

them after erection is scarcely lessened by a previous reduction of the litharge at the works. On the other hand, negative plates previously reduced have always a tendency to scale and blister during the first charge, owing to the hard coating of sulphate of lead on their surface.

To simplify the manufacture as much as possible, only two types of plates, A and B, are now used in stationary Tudor cells. The A type has the dimensions 7 inches wide × 12 inches high, and the B type 14 inches wide × 12 inches high; for the purpose of renewals in existing batteries, a third type, D, is made, of which the dimensions are $9\frac{3}{4}$ inches wide × $9\frac{3}{4}$ inches high; but no new cells are supplied with these plates. The thickness of all types of plates is the same, the positive plates being ·5 inch and the negatives ·4 inch thick.

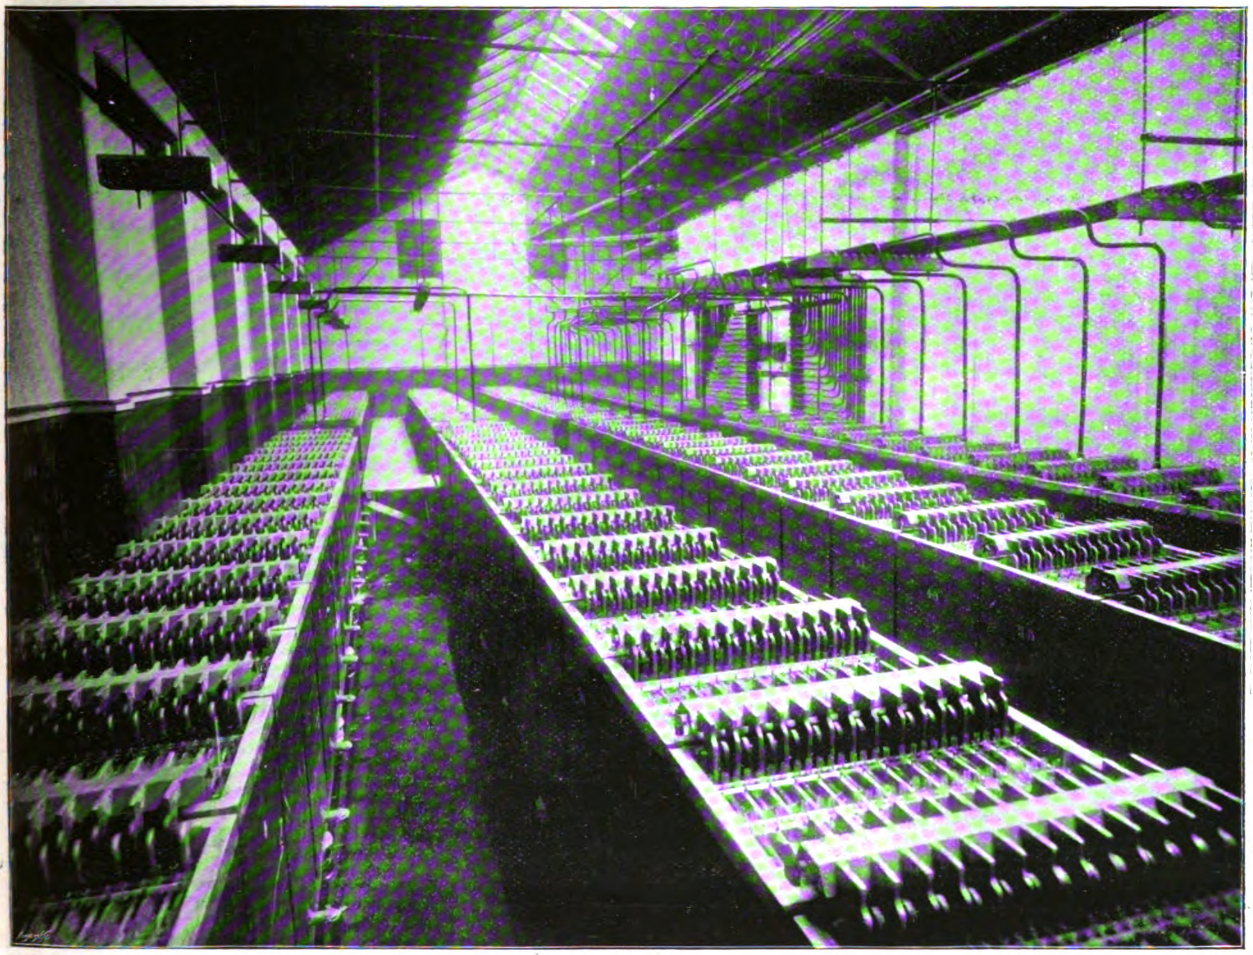


Joiners' Shop.

between the two plates so as to allow for their expansion in ordinary working. The size of the finished plate is about 16 inches wide × 25 inches high, and its appearance is shown in the accompanying sketch. The negative C plates are made of two negative B plates, the lower edge of one being solidly burnt to the upper edge of the other. To give greater rigidity to negative plates of this size, they are made of antimony lead alloy.

The plant at present in use at the Dukinfield works comprises a Marshalls 50 I.H.P. semi-portable compound engine, driving by belts two 20-kilowatt dynamos, and a similar 75 I.H.P. engine driving one 35 and one 20-kilowatt dynamo. Arrangements are already being made for putting down a third engine of 100 I.H.P. with corresponding dynamos.

The switchboard has all the necessary cut-outs, switches



Tudor Accumulators at Glasgow Central Station.

For the largest type of plate, known by the makers as the C type, the lugs are removed from two positive B type plates, which are solidly burnt at either side to two hard lead strips. These side strips are cast in one piece with the connecting and suspending lugs. A space of about half an inch is left

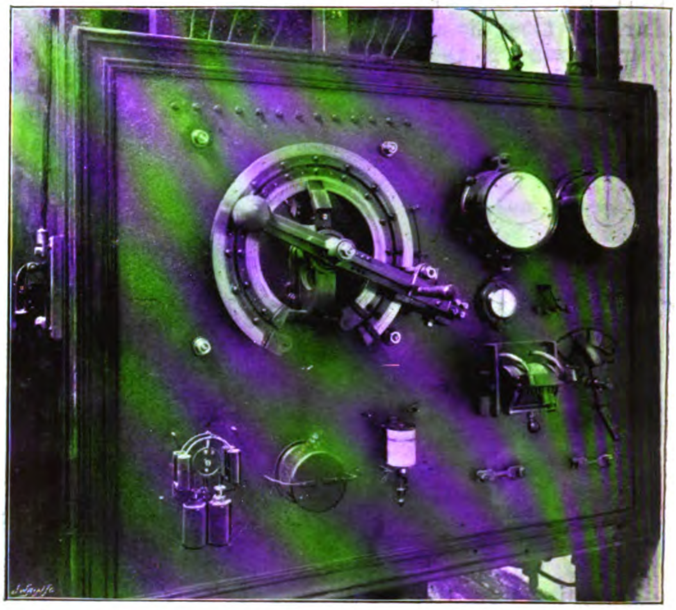
and instruments, and an automatic minimum cut-out on each dynamo. In the circuit of each dynamo is a multiple way switch allowing any dynamo to be put on any of the formation batteries, of which the voltage is so variable that it has been found impossible to group them in parallel. A special boiler for distilling water, is also placed in the engine-room. Distilled water is a feature of the Tudor accumulators, and large quantities are used in the works, both for working the batteries and in the formation cells.

The rest of the works are composed of the plumbers' shop, where the wood boxes are lined, C type plates are made, and all general plumbers' work with the hydrogen blow-pipe is carried out; the joiners' shop, where the boxes, stands, and packing cases are made, a few machine tools being used in this work; a small engineers' shop; the pasting shop, where the negatives are pasted as before described; and, lastly, the packing-shop and stores.

It may be mentioned that all the tools are driven by electric motors, of which there are about half a dozen; these take current from the lighting circuit of the works, which is entirely fed by a special battery, charged twice a day during the winter months. Owing to the sudden variations of output, due to the starting and stopping of the motors, the voltage would be very unsteady, were it not for the automatic regulating switch of the Trumpy pattern, which keeps the voltage perfectly constant. We have previously described the operation of this switch, and we now show an illustration of the one in use at Dukinfield.

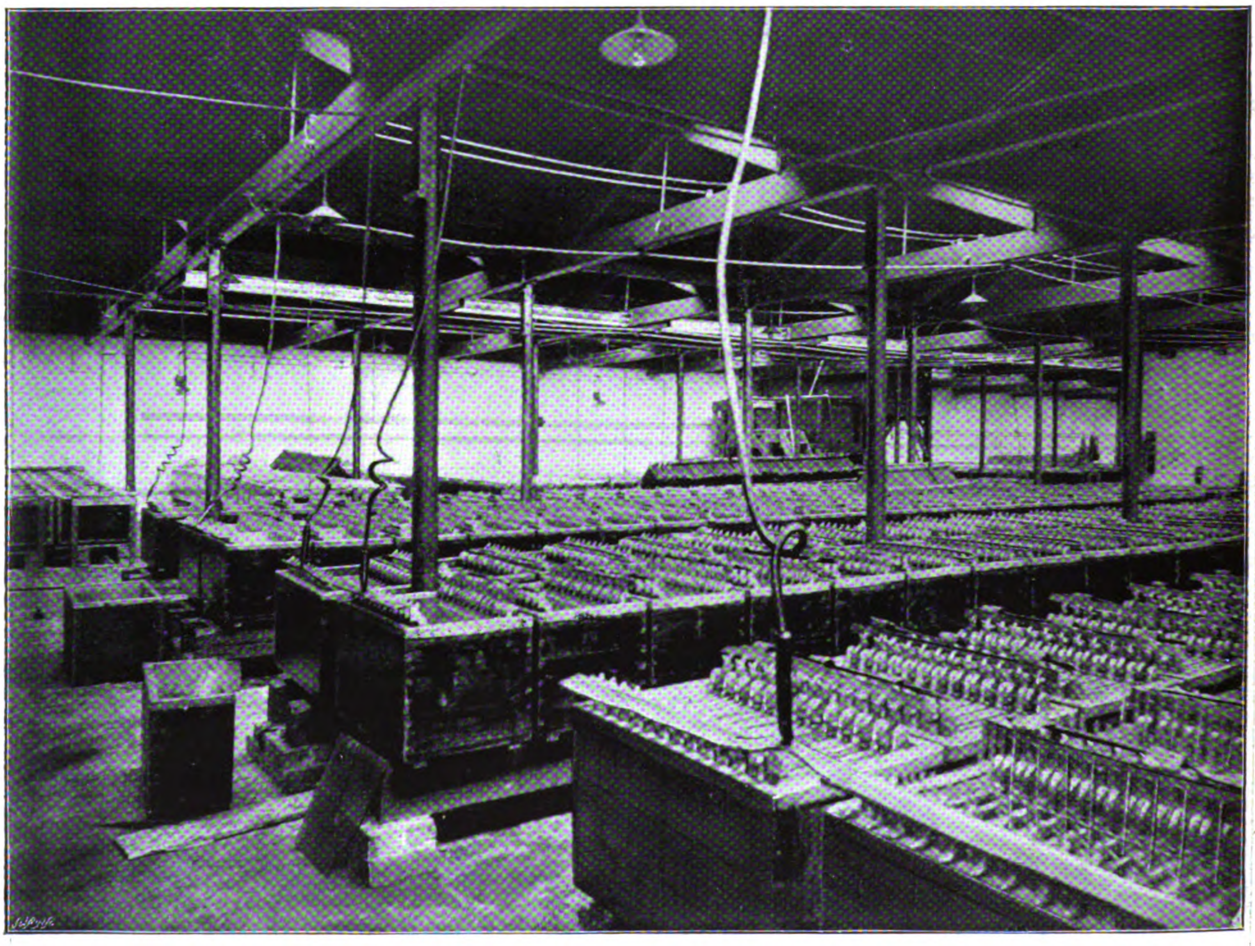
It may be interesting to close the account of the manufacture of Tudor cells with a short description of the two batteries recently put in at the Glasgow Corporation sub-stations.

The general view of one of these batteries, at Tontine Lane, Glasgow, is shown in the accompanying photograph. This battery is composed of 134 cells, type H.C. 27, each containing 27 plates of the C type. The output is 2,080 ampere-hours, or 1,040 amperes for two hours with a minimum voltage of 240 volts. The cells are capable of giving a maximum output of 1,820 amperes for one hour, and may be charged with a current of 780 amperes. The size of each box is 2 feet 9 inches × 1 foot 11 inches × 3 feet high, and the weight of each cell when filled with acid is 18 cwt., making a total weight of 120 tons for the whole battery.



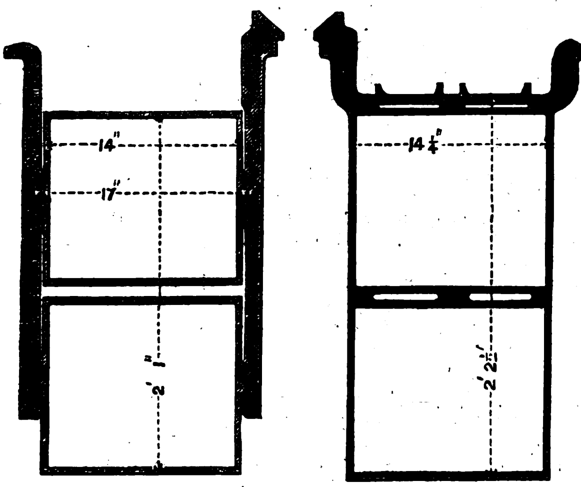
The Trumpy Automatic Switch.

The second battery at Claremont Street, Glasgow, is similar in every respect, but is slightly smaller. There are 126 cells, each containing 25 C plates, the output being 960 amperes for two hours. This battery weighs 110 tons.



Formation Room.

These batteries are interesting as being, we believe, composed of the largest size of cell at present in use in the kingdom; they are, at the same time, a good example of the way in which the floor space required by large batteries may be reduced, without arranging in two tiers, the upper of which is always neglected.



POSITIVE PLATE. NEGATIVE PLATE.

We are much indebted to Messrs. Pescatore for their courtesy in allowing us to inspect the process of making Tudor plates; also to Mr. Jacob for the information embodied in the foregoing description.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

(*Continued from page* 112.)

Laxey and Ramsey Electric Railway.—We are informed that the order for a battery of very considerable dimensions has been placed with the Chloride Electrical Storage Syndicate, Limited, which will be employed in connection with the extension of the Douglas and Laxey Railway, in the Isle of Man, to Ramsey. Their batteries are already installed on the Douglas and Laxey section and the Snaefell branch of the line.

Norwich.—The Town Council has approved of the application to be made to Parliament in the ensuing session by the Norwich Electric Tramways Company, for an Act to authorise that company, amongst other things, to make and maintain additional tramways.

Staffordshire.—At a recent inquiry at Kingswinford held by Colonel J. T. Marsh, R.E., it was stated that the scheme of the British Electric Traction Company involved about 50 miles of tramways, and the company were to have the tramways 24 years, when the local authorities could purchase.

The Power Distribution Scheme.—The members of the South Staffordshire Iron and Coal Masters' Association attended at the Queen's Hotel, Birmingham, last week, to consider the scheme brought forward by the Midland Electrical Corporation for Power Distribution, Limited. Sir Benjamin Hingley, who presided, pointed out that they now depended upon steam, but abroad electrical distribution by means of electric wire attached to machines and tools had been adopted with the greatest possible success and economy. Although changes were sometimes expensive and unpleasant, if South Staffordshire was to hold its ground with its competitors they must face those disadvantages. The local authorities could only distribute power at 3d. per unit, whereas it could be done by private enterprise on a great scale at one-half or one-third the cost. Colonel J. B. Cochrane, chairman of the South Staffordshire Coal Trade, stated that difficulties had been experienced for some time past with regard to dealing with storm water, and preventing their mines being drowned out. If they could get electric power supplied to the low-lying districts they could economically deal with storm and other water by making reservoirs, and so getting rid of the bulk of the storm water, which was so injurious to the mines. The Mines' Drainage Board had spent £30,000 or £40,000 in putting down heavy pumping engines to deal with that water which ought to be dealt with on the surface. Mr. J. F. Albright, on behalf of the Midland Electric Corporation, explained the objects of the undertaking. It was intended to supply the South Staffordshire district with electrical power, and when Parliamentary authority was obtained a large generating station would be erected in a central situation. From the switchboard seven or eight circuits would radiate to different parts of the districts, and the current would be available day and night, and on Sunday, for power and lighting at prices varying from 3d. to 1d. per unit. The Corporation proposed to rent motors to manufacturers, and to act as power bankers. The Chairman proposed a resolution affirming that the proposals were worthy of support, and should be encouraged instead of being opposed by local authorities, subject to fair conditions, so as to secure economical terms to consumers, a copy of the resolution to be sent to each local authority and the Board of Trade. Sir A. Hickman, in seconding, remarked that if the Corporation came to a vague proposal as to price of between 1d. and 3d., he did not think the ratepayers of Wolverhampton would be inclined to admit a competitive company, but if they were prepared to give power at 1d. per unit, all the Corporations would gladly welcome the company. As time went on coal would decrease, and any Corporation that ventured to oppose a scheme of this kind would be taking upon themselves very grave responsibilities. Mr. Hooper (Dudley) suggested that the local authorities should have the right of distributing power in their own areas, taking power from the Midland Electrical Company.—Mr. Albright said that the price would depend upon the nature of the demand. Broadly speaking, they were prepared to supply current at 1d. per unit to customers who would take it for the necessary number of hours. In the course of a discussion, Mr. W. Bassano informed the meeting that at his collieries electric haulage and pumping had been found most successful and economical. He also endorsed the remarks already made as to the advantage which the scheme would be to the work of the Mines' Drainage Commissioners.—Mr. Garcke (British Electric Traction Company) said that a large portion of the scheme for supplying electric traction to the district was lying dormant, because of the difficulty of getting power from the local authorities at anything like the price which the company would offer it.—Mr. A. Keen suggested that "worthy of support" in the resolution should be altered to "worthy of consideration." He contended that the proposal meant a monopoly. He was prepared to consider anything, but to support it was another matter.—The resolution was altered as suggested, and carried with one dissentient.

The Walsall District Council will support the application of the Midland Electric Construction Company for a provisional order for the supply of electricity to the district.

The "Underground."—In connection with the suggestions of the Departmental Committee appointed to go into the system of ventilation of the tunnels on the Metropolitan Railway lines, the directors in their report to the shareholders quote the recommendations to which we referred in the REVIEW some months back. They desire to express their sense of the value and importance of the inquiry, and they have embodied in the company's Bill, deposited for the next Session of Parliament, powers to enable the company to give practical effect to the committee's recommendation. The Bill deposited provides for powers to improve the ventilation of the railway; to authorise the working of the traffic of the railway by electricity; to alter the levels of the railway in the parish of Willesden, and for other purposes.

TELEGRAPH AND TELEPHONE NOTES.

French-American Cables.—A Washington despatch says that the Acting Attorney-General has decided that the President has power, in the absence of any legislation on the subject, to control the landing of a foreign submarine cable. The question was raised by the action of a French Company, which landed a cable at Cape Cod without the express permission either of Congress or the President.

Portsmouth Telephone Service.—The Council of the Local Chamber of Commerce in the report submitted to the annual meeting, states that, at the instance of the Chamber, the promised underground metallic circuit had recently been completed, and had remedied the disturbance to the telephonic system caused by the electric lighting of the town, which disturbance during its existence rendered the telephone practically useless. The Council were now in communication with the National Telephone Company on the subject of the high rentals charged, and the need for better instruments. They were also in correspondence with the Postmaster-General with the view of improving the use of the trunk system, which is at present hindered by all messages having to go through Southampton, and there being only one wire from that place to London. A second wire from Southampton to London is nearly completed, but the Council were of opinion that the only satisfactory remedy as regards Portsmouth is the construction of a trunk line direct to London, so preventing the present delays. It is also thought by the Council that to render the trunk system acceptable to the public, the tolls must be considerably reduced, the present charges being almost prohibitory.

Telegraph Monopoly in Mexico.—The Mexican Government has entered into a contract with the Western Union Telegraph Company and the Mexican Telegraph (Cable) Company, an American corporation, whereby the communications of Mexico by wire with foreign countries are to be concentrated in the federal telegraph system and the systems of the two corporations above mentioned. In other words, says the *Financial News*, the Government, the Western Union, and the Cable Company are to have the exclusive right—the monopoly—of the foreign or international telegraph business of Mexico, to the exclusion of the railway wires and those of any other corporation. This is stated explicitly in Article 26 of the contract. It is declared in Mexico that the deal raises "an important point which will probably become the subject of protracted litigation, until a test case is made of it by a final decision of the Supreme Court."

The Telephone Service.—The Beckenham District Council has unanimously passed a resolution requesting the Postmaster-General to grant licenses for telephone service, without inquiry as to the charges or efficiency of the present service, to any municipalities or companies complying with the requirements of the Treasury minute of May 23rd, 1892.

The *Daily Chronicle* says that, speaking at the annual meeting of the Halifax Chamber of Commerce on Tuesday, Sir James Fergusson, M.P., director of the National Telephone Company, said there were numerous complaints respecting the company's service. Many people expected impossibilities, but a new science which was being gradually developed must for a long time leave a good deal to be desired. The great difficulty was that, unlike the Post Office, the company had no power to place wires underground. But the authorities of every town in England, he believed, had now given the necessary consent, and all would soon be enjoying a vastly improved twin wire underground system.

At a meeting of the North Staffordshire Chamber of Commerce, at Hanley, on 19th inst., it was reported that the replies received to questions submitted by the secretary to the members of the Chamber and to the Town Clerks of about 60 places, with reference to the working of the telephone system, showed the general opinion to be that the present charge for the telephone was not a reasonable one; and that the telephone service at present obtainable was unsatisfactory for a variety of reasons.

The Glasgow Corporation has received no further information regarding Sheriff Jameson's report.

Mr. Morton, according to the *City Press*, has no intention of allowing the question of the telephone monopoly to drop out of sight. At the meeting of the Court, yesterday, he was to propose the convening of a conference at the Guildhall, with a view to the local authorities uniting in a demand for a Government inquiry to be held.

CONTRACTS OPEN AND CLOSED.

OPEN.

Ashton-under-Lyne.—February 2nd. The Baths Committee want tenders for the installation of the necessary wires and fittings for the electric lighting of the Corporation Baths. Consulting engineers, Messrs. Lacey, Clirehugh & Sillar. See our "Official Notices" January 14th for particulars.

Bilbao.—February 28th. The Secretary of State for Foreign Affairs has received a despatch from Her Majesty's Consul at Bilbao, reporting that the provisional board appointed in connection with the electric tramway which it is proposed to lay from Zumarraga to Zumaya, in the province of Guipuzcoa, invite plans and tenders, to be received by February 28th, for the construction and equipment of the line. Further particulars of the conditions of the tenders for the above-named tram line and branch, which together measure 30 miles, may be inspected at the Commercial Department of the Foreign Office any day between the hours of 11 and 6.

Belgium.—February 11th. The Provincial Government Authorities in Brussels are inviting tenders for an installation of electric lighting in the offices of the Governor of Brabant in the Rue de Chêne, Brussels. Tenders to be sent to the Gouvernement Provincial, Brussels.

Berlin.—March 15th. The Municipal Traffic Deputation of the Town Council have opened a competition for the construction of several new electric tramways in that city. Exhaustive details concerning this project are contained in the *Elektrotechnische Zeitschrift* of the 13th inst., which mentions that proposals will be received by the Stadtische Verkehrsdeputation Rathhaus III, Berlin, by March 15th.

Bradford.—February 1st. The Corporation is inviting tenders for the electrical equipment of about nine miles of street tramways. There are three contracts for the following sections:—(1) steel poles, bracket arms, &c.; (2) trolley wire, insulators and overhead equipment; (3) cars, trucks, motors and trolley poles. Particulars from the city surveyor or the city electrical engineer at the Town Hall.

Brighton.—January 31st. The Town Council want tenders for dynamos, motors, switchboards and wiring for the electric lighting of the Municipal School of Science and Technology. Specifications from the town clerk's office.

Edinburgh.—February 5th. The Corporation want tenders for the wiring of the Police Station, Abbeyhill. See our "Official Notices" for particulars.

France.—March 31st. Tenders are being invited by the Municipal Authorities of Saint Chamond (Loire) for the concession for the lighting of the public streets of the town, either by gas or electricity. Particulars from, and tenders to be sent to, La Mairie de Saint Chamond (Loire).

Harrogate.—January 31st. The Corporation wants tenders for the supply of hard steam nuts for six or twelve months' supply (minimum quantity 1,500 tons per year). Particulars from the electrical engineer, Mr. Geo. Wilkinson, Corporation Electricity Department.

Leicester.—January 31st. The Leicester Corporation invites designs and tender for motor vehicles for the collection of house refuse. Specifications and particulars, with drawings, to be sent to the Chairman of the Sanitary Committee, to the office of Mr. E. Geo. Mawbey, C.E., borough engineer, Town Hall, Leicester.

London, E.C.—February 2nd. The City of London Electric Lighting Company is inviting tenders for the purchase of various quantities of superior secondhand cables which has recently been in use on the company's continuous current series arc circuits, but has been found unsuitable for the high pressure (about 3,000 volts) required. It is stated to be adapted for house-wiring or for making connections to supply mains. See our "Official Notices" this week for fuller details.

Madrid.—February 22nd. The Secretary of State for Foreign Affairs has received a despatch from Her Majesty's Chargé d'Affaires at Madrid, enclosing copy of a Royal decree announcing that a public auction for the contract for repairing the national submarine telegraph cables during the next five years will be held at Madrid on February 22nd. Further particulars as to the cables in question may be inspected at the Commercial Department of the Foreign Office any time between the hours of 11 and 5.

Redditch.—February 14th. The District Council want tenders for the supply of buildings, gas producing plant, gas engines, alternators, cables, transformers, &c., for the electric lighting of the district. Consulting electrical engineer, Mr. J. A. McMullen. See our "Official Notices" this week.

Rochdale.—February 19th. The Corporation want tenders for steam dynamos, balancer, and boosters, &c. Engineers, Messrs. Lacey, Clirehugh & Sillar. See our "Official Notices" January 14th.

Roumania.—March 15th. Tenders are being invited by the General Direction of the Roumanian Post and Telegraphs in Bucharest for the supply of 56,000 metres of galvanised iron and steel wire.

Spain.—The municipality of Sophia is inviting tenders for the joint concession for (*a*) electric lighting of the town; (*b*) electric tramways in the town and suburbs. *Daily Tenders* for 26th inst. gives the conditions of tendering.

Spain.—February 1st. Tenders are being invited by the Municipal Authorities of Tarifa (Cadiz province) for the 20 years' concession for the lighting of the public streets of the town by electricity, acetylene or gas. Tenders to El Secretario del Ayuntamiento de Tarifa (Cadiz) from whom particulars may be obtained.

Spain.—February 8th. Tenders are being invited until February 8th by the Municipal Authorities of Tordesillas, a small town in the province of Valladolid, for the concession for the electric lighting of the public streets during a period of 20 years. Particulars may be obtained from, and tenders should be sent to, El Secretario del Ayuntamiento de Tordesillas (Valladolid).

Spain.—February 11th. Tenders are being invited by the Municipal Authorities of Valderas (Leon province) for the concession for the electric lighting of the public streets of the town during a period of 17 years. Particulars may be obtained from, and tenders to be sent to, El Secretario del Ayuntamiento de Valderas (Leon).

St. Helens.—February 21st. The Corporation want tenders for various plant and machinery, &c., in connection with the proposed electric tramways. See our "Official Notices" this week for particulars. Consulting engineer, Dr. J. Hopkinson.

Stockport.—February 3rd. The Corporation is wanting tenders for various plant and machinery for electricity supply works at Millgate, Stockport, including Lancashire boilers, steam dynamos, feed water heater, storage battery, electrical instruments, electrical connections, wiring, &c., at the generating stations, also underground cables. Electrical engineer, Mr. James N. Shoolbred, 47, Victoria Street, S.W. See our "Official Notices" January 14th, and supplementary notice this week.

Wimbledon.—February 2nd. The District Council wants tenders for the supply, delivery and erection of water tube boilers, condensing plant, overhead crane, high speed steam engine and alternator, switchboard, underground mains, conduits, &c. Consulting engineer, Mr. A. H. Preece. See our "Official Notices" January 14th for particulars.

CLOSED.

Barking.—The Council has accepted the tender of the Sunderland Forge Company for an overhead crane at £70. The order for 66 lamps with switches and fuses at 35s. each, also 300 lamps with switches but without fuses at 20s. each, has gone to the Reason Manufacturing Company, Limited. Mr. Sharpe's tender has been accepted for the erection of the electric light station and shaft at £2,666.

Canterbury.—The list of tenders recommended for acceptance in connection with Mr. Hammond's electric lighting scheme, which were noted in our issue of January 14th, came before the Town Council last Friday, and the tenders were accepted.

Hammersmith.—On Wednesday last week the Vestry gave out the contract for the supply of two alternators, exciter and spare parts, at £3,600, to the Electric Construction Company.

Melbourne.—Messrs. C. A. Parsons & Co., of Newcastle, have, according to a Sydney paper, received a contract from the Government Railways Department for four steam alternators, the amount being £7,604 odd.

Sydney.—For the feeder cables and junction boxes for the Sydney electric tramways (George Street and Harris Street) the tender of Messrs. Noyes Bros., of Sydney, has been accepted at schedule rates.

FORTHCOMING EVENTS.

1898.

Friday, January 28th, at 8 p.m.—The Institution of Civil engineers. Students' meeting. Paper to be read on "Condensing Apparatus," by H. Williams, Stud.Inst.C.E.

Saturday, January 29th.—Institution of Junior Engineers, Westminster Palace Hotel. Reception at 6.30 p.m. Dinner at 7 p.m.

Monday, January 31st.—Yorkshire College Engineering Society. Mr. J. A. McLaren on "Electrical Engineers' Specifications."

Latest date for tenders for electric lighting plant of the Municipal School of Science and Technology. Also Leicester tenders.

Tuesday, February 1st.—Latest date for Bradford electric tramway plant tenders.

Wednesday, February 2nd.—Institution of Electrical Engineers. Students' meeting. Paper to be read entitled "Comparison of Gas and Electricity as used in Tramway Work on the Continent," by O. M. C. Heyl, student.

At 8 p.m.—Society of Arts. "The Cinematograph," by Jules Fuerst. Captain W. de W. Abney, C.B., F.R.S., will preside.

Liverpool Engineering Society. Paper by Mr. W. H. Preece, C.B., F.R.S.

Latest date for Ashton-under-Lyne tenders.

Latest date for electric lighting plant tenders for Wimbledon.

Thursday, February 3rd, at 8 p.m.—Chemical Society. Papers to be read:—"On the Dissociation of Potassium Platini-Chloride in Dilute Solution, and the Production of Platinum Mono-chloride," by E. Sonstadt; "Effect of the Mono-, Di-, and Tri-chloracetyl Groups on the Rotatory Power of Methylic and Ethylic Glycerates and Tartrates," by Percy Frankland, F.R.S., and Thomas Stewart Patterson, Ph.D.; "The Rotation of Ethylic and Methylic Di-monochloracetyl-tartrates," by Percy Frankland, F.R.S., and Andrew Turnbull, Ph.D.; "The Volumetric Estimation of Sodium," by H. J. H. Fenton, M.A.

Meeting of the Chemical Society at Burlington House.

Friday, February 4th, at 8 p.m.—The Institution of Junior Engineers, at the Westminster Palace Hotel. Paper on "Electro-Magnetic Brakes, and their Capabilities," by Mr. Louis H. Walter, A.I.E.E., of Cambridge.

Royal Institution. Mr. A. A. Campbell Swinton on "Some New Studies in Cathode and Röntgen Radiations."

Saturday, February 5th.—Institution of Electrical Engineers. Student's visit to the works of Messrs. Siemens & Co., Woolwich. Train from Fenchurch Street, 10.5 a.m. Applications to join the party, to the Student's Hon. Sec. (Mr. S. Grant, 28, St. Mary Abbot's Terrace, W.)

Tuesday, February 8th.—Liverpool Overhead Railway Company. Meeting at Liverpool.

Thursday, February 10th, and Friday, February 11th.—The annual general meeting of the Institution of Mechanical Engineers, at 25, Great George Street. The discussion on Mr. Philip Dawson's paper on "Mechanical Features of Electric Traction," will be resumed. A paper will be read and discussed as follows: "First Report to the Gas Engine Research Committee; Description of Apparatus and Methods, and Preliminary Results," by Prof. Frederic W. Burstall.

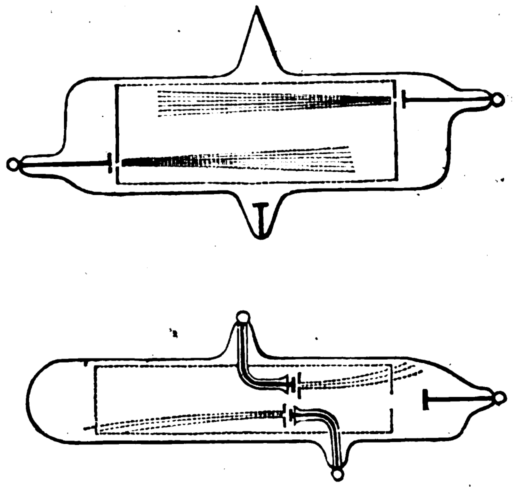
NOTES.

Electrolysis by Traction Currents.—Though there can be no doubt, from theoretical considerations, that the corrosion of underground pipes is accelerated by the leakage currents from electric railways, it has always been difficult, for obvious reasons, to obtain statistics of the exact amount of damage done. In the *Street Railway Review*, December 15th, 1897, an interesting fact is mentioned, which seems to show that traction leakage currents are not the only cause of electrolytic corrosion. "One of the best railway electricians in the country discovered what, to all appearances, is a most pronounced case of electrolysis in a gas pipe in this city, but which, at the time he made the excavation, was many miles removed from any electric line, and, indeed, was separated from the nearest line by a river. It is valuable evidence and convincing, that destruction of water pipes can and does occur without the presence of trolley lines, and the question naturally arises whether the electrolysis in the past, which has been discovered since the advent of electric lines, was due to them to any such extent as has been supposed. While there were in the early days unmistakable cases traced to these lines, it is not unlikely that natural earth currents and acids in the soil largely contributed to the results in many cases, which were discovered by reason of the construction of electric railway lines." In the same journal is given an account of several cases of corrosion due to traction currents that occurred in Salt Lake City and Chicago. In one of these cases, the corrosive action was strongest about a crack in the pipe, from which water had been slowly leaking into the ground. It was supposed that the superior conductivity of the wet ground had concentrated the current on this part of the pipe. The reports of the engineers of these lines shows that faith has not yet died out in such old-fashioned and exploded remedies as bonding the pipes to the rails, or bonding the rails to an uninsulated return conductor. In several cases an overhead return conductor connected to the rails at short intervals is recommended, though it is not explicitly stated whether this conductor is insulated or not.

Effect of Röntgen Rays on Plants.—An exhaustive series of experiments has recently been made by Prof. Atkinson, of Cornell University, to determine the action of the Röntgen rays on growing plants. (*Science*, January 7th, 1898). The results, unfortunately, are of a very negative character. He found that, though plant tissues absorb the Röntgen rays quite freely, there is no marked influence on the growing parts. There are no visible external injuries, even when the parts are exposed at close range a large part of the time during several days. This is the more remarkable, since the general impression is that the rays, even with comparatively short exposures, are injurious to the human tissues. The rays were found to have no toxic or turning influence on plants. No difference in growth was produced by exposure to the Röntgen rays; the rays neither inhibited or hastened growth. Bacilli were exposed for hours to the rays, but it was found that they had no influence on the distribution of the bacilli in the liquid, nor on their vitality for the length of time of the exposure.

Electrical Installation Rules.—The new edition for 1898 of the Electrical Installation Rules of the Liverpool and London and Globe Insurance Company, forms the third year's issue of the new copyright compilation, displacing their former rules dating from 1888 or earlier. The value of this periodical re-issue is shown in the present edition by the inclusion of several added rules this year. For instance, the growth of the adoption of "free wiring" in various districts has necessitated rules specially dealing with the lead-covered twin wires used in this class of work, and the extension of the use of electricity for tramway work has lead to the prohibition of the use of trolley wires or of dynamos feeding trolley wires as a direct source of current for lighting or power upon insured premises other than the power stations, sheds, &c., of the tramway people. Further slight additions deal with precautions desirable in specific risks, such as corn, oil, and textile mills.

Mutual Influence of Cathode Rays.—Some interesting experiments, accompanied by rather hesitating conclusions, are contributed by Julius Bernstein, in *Weid. Ann.*, on the subject of the apparent repulsion between two beams of cathode rays, first observed by Crookes, and interpreted by him on the supposition that cathode rays consist of projected particles, and are equivalent to elastic conductors carrying a current. As might have been expected from a German source, says the New York *Electrical Engineer*, Bernstein's results tell against this view, and in favour of some kind of wave hypothesis. In the first place he investigated the influence of the direction in which the rays travel. Mounting two cathodes, one at each end of the tube (see fig. 1) with a slit in front of each, he obtained two opposite beams running side by side, which did not affect each other



Figs. 1 and 2.

in any way. But when the cathodes were placed side by side (fig. 2), the beams were bent outward as long as the glass funnels protecting the wires left the cathode plates bare. When they projected beyond their surfaces, no effect was produced. The direction of the emerging rays is, therefore, of no account. Further experiments proved that the action is probably exerted by one cathode upon the beam from the other cathode at its origin. But to this action an electrostatic effect between the cathodes may be added.

Accumulator Boxes.—The high price of these "recipients"—as they are termed on the Continent to distinguish them from what is technically termed the "cell," and also from the outer boxes—has long been an inducement for the invention of a new material to be used in their construction. In a recent discussion at the Institution, Mr. Wallis Jones referred to the "breakages of ebonite cells, which, on the average, may be taken to cost 10s. a piece." Celluloid has been proposed and used to some extent; it is not liable to fracture, but its great combustibility constitutes so great a danger that its employment on a large scale is out of the question. We have seen some samples of a new material, invented by Mr. Desmond FitzGerald, and called by him "Acrematin," which seems well adapted for the manufacture of these receptacles, being acid-proof, strong and comparatively cheap. It would appear to be adapted also to many other purposes.

Vacuum Tube Lighting.—An American correspondent writes as follows:—"With reference to Tesla's vacuum tube light mentioned in the current electrical journals, D. McFarlan Moore, of Newark, N.J., who lit a room by vacuum tubes at the electrical exhibition in New York in May, 1896, has just made a statement, claiming Tesla's present system to be a copy of his. There is certainly a similarity. Moore interrupts a self-inductive circuit in a vacuum, and connects one terminal of the tube to be lighted to one side of the break, and the other terminal to the opposite side. Tesla interrupts a self-inductive circuit in the open air, and to light a tube, raises the potential of the induced current by a step-up transformer, the secondary of which is connected around the break, and has a condenser of suitable capacity in its circuit. This arrangement he calls an electrical oscillator."

Electric Cranes in Railroad Shops.—Electricity is very largely used for working the cranes at the Crewe shops of the London and North-Western Railway. The motors, says *Engineering*, have field-magnets of the Manchester type, and Paccinotti armatures. In starting a motor, a variable resistance is switched in to diminish the starting current, being cut out when the motor is fairly running. All the motors used are designed to run at 1,500 revolutions per minute, the speed being afterwards reduced by worm gearing. In the case of the 30-ton cranes used in the erecting shops for lifting locomotives, the load is lifted at a speed of 2 feet 6 inches per minute, at an expenditure of 70 amperes at 120 volts. The long travelling is performed at a speed of 100 feet per minute, with an expenditure of 60 amperes at 120 volts, and the cross traverse at a speed of 50 feet per minute, with an expenditure of 30 amperes at 120 volts. In the case of light weights the speed of lifting is 10 feet per minute. In the case of the 15-ton crane, which has been provided in connection with a boiler-riveting plant, the crane is 50 feet above the floor level, and all its movements are controlled by switches on the ground, a magnetic brake being provided on the armature shaft to arrest the motion as soon as a rivet-hole has been brought into place for the closing of the rivet. The cost of repairs has, Mr. Webb states, so far been very small; no renewal of commutators has been necessary, but they are lightly skimmed up in the lathe about once in 12 months. The carbon switches and brushes are renewed once in six months.

Cabby's Farewell to his Steed.—The *St. James's Gazette* recently had the following:—

So long, old 'oss; you're jest played out, you've taken your last fare,
Your quarters are the knacker's nah, and mine are Lord knows where;
There ain't no room in London nah for either you or me,
We're crahded aht by cabs as go by electricitee.

It warn't all beer and skittles, even in the palmy days,
What with the cove with principles, his legal fare as pays;
But when the "biz" was pretty brisk, and cabby got the pull,
I could plank dahn for the Derby for my fancy arf a bull.

It's nuts, it is, on some fine day, to pick up some young nob,
And drive 'im all the morning till the fare is nineteen bob;
And then he stops at Gresham 'Ouse, and shahting, "Cabby, wait,"
'E takes 'is 'ook the other end aht into Bishopsgate.

Or on a lovley autumn when the rain came dahn in sheets,
Or when a bloomin' blizzard set us skatin' in the streets,
And after you 'ad planked dahn to the yard each bob you 'ad,
And fahnd yerself to balance up a dollar to the bad.

Then to take yer to the stables at the other end of tahn,
And strip yer frozen 'arness off, and rub yer old 'ide dahn;
And yer got yer jolly skin full, and a decent place to doss,
Which was often more nor *I* got by a jolly site, old 'oss.

But nah—so long, my beauty; for this latest style I bar—
I ain't a going (what do *you* think) to run a motor-car;
While there's a crossing to be swept, a job to do—no fear—
I reckon I'm too old to turn a bloomning engineer.

American Electrical Apparatus for England.—With respect to Mr. Justus Eck's recent visit to the United States, the *Street Railway Journal* says that the purpose of this visit was to make arrangements with American houses to represent them in Great Britain, and in this he was highly successful. Mr. Justus Eck's company (Messrs. Laing, Wharton & Down) already represents the well-known Walker Company here, and among the new agencies secured is that of the Ward-Leonard Company, manufacturers of Carpenter enamel rheostats and other appliances; that of the Wagner Electric Manufacturing Company, of St. Louis, for its alternating current apparatus of all kinds; that of the Q. & C. Company for its rail-sawing apparatus, and that of the Pearson jack. The Buda track drill, for which the company has been for some time agent, has been quite largely sold in Great Britain through its efforts. Mr. Eck also made arrangements for establishing a permanent purchasing agency in New York for any supplies needed in this country for carrying out the extensive work which Laing, Wharton and Down are now organising to undertake in Great Britain and elsewhere.

The Royal Society.—Among the papers down for reading yesterday afternoon were the following:—E. Wilson: (1) "The Kelvin Quadrant Electrometer as a Wattmeter and Voltmeter." (2) "The Magnetic Properties of almost Pure Iron."

The City and Guilds of London Institute.—The Finance Committee of the City Corporation have recently reported on the application of the Council of the City and Guilds of London Institute, for a renewal of the grant from the Corporation to the funds of the Institute. They state from inquiry that the work of the Institute has been successfully and economically managed, and the results achieved are fully commensurate with the expenditure involved. Although in the past season there was a decrease in the total number of students in regular attendance, the work of the Institute was, on the whole, well maintained. At the Central Technical College, 214 students were attending special courses, and an average of 170 were under instruction in each of the four departments which constituted the regular curriculum of the Institute. The technological examinations attracted 29,494 students, as against 27,583 in the previous year. At the Technical College, Finsbury, there were 184 day and 900 evening students—a slight decrease in both categories. Since it opened in 1884, nearly 1,200 day students had entered. The development of the chemical department was remarkable, and the high quality of the work done by the students fully maintained. The income of the Central Institute, including school fees, was £33,079, and the cost of the several branches £28,578. The gross cost per student was £54. The Corporation of London has, in consequence of this report, voted £400 in respect of last year towards the funds of the Institute, to be devoted to the Finsbury Technical College. This will make upwards of £16,000 contributed in all by the Corporation towards the Institute.

Testing Extraordinary.—Mr. S. L. Corson, writing to the *American Electrician*, says:—"That there are 'tricks in all trades but ours,' is a foregone conclusion among the members of the various crafts, and the thought and ingenuity expended upon some of the tricks and dodges would, if expended in true work, increase the salary and standing of the trickster to a notable degree. A case in point:—The engineer of a small isolated lighting plant, not 1,000 miles from New York City, was informed that a test of his plant would be run to determine the cost of lighting the building, after which, current from Edison street mains would be turned on, and the cost of thus lighting for a similar period be ascertained. The engineer knew that if the Edison service cost less than it did to make the current by the plant that he was in charge of, his occupation would be forfeited. Therefore, when the trial run was made, never was boiler, engine or dynamo in better condition than his, and the coal burned was very small. When the Edison trial was made, he had figured out the cost of everything, and knew to a dot what current could be received, and still retain his place. A cunningly concealed water rheostat in the adjoining building was connected by concealed wiring, and the economy of the Edison current received so severe a set-back during the test run, that the engineer is sure of his job for some time to come, unless he gets found out. While not speaking well for the trustworthiness of the engineer, it speaks still worse for the skill of the Edison 'expert' who conducted the test for his company. He should have detected the fraud immediately."

The Extraction of Metals and Metallic Alloys by Means of Electrical Heat.—A new process, which is being exploited at Cassel, in Germany, by H. Aschermann, consists in the extraction of metallic alloys and pure metals by electric heat from a mixture of the oxide, of a metal and the sulphide of another metal or of a metalloid, or of the oxide of a metalloid and the sulphide of a metal, the object being to accelerate the reduction, and eliminate the carbon and other impurities. The metal is obtained in the form of an alloy, from which the more fusible metal can be separated by distillation if desired. Sulphide of antimony is preferably employed as the flux; for instance, in the preparation of chromium, 10 parts of chromium oxide are mixed with 23 parts of sulphide of antimony, and placed as cathode in an electric fusion furnace, and treated by a current of 20 to 25 amperes, and the antimony is driven from the resulting alloy by reheating. Similarly, aluminium may be obtained from a mixture of 10 parts of its oxide with 37 parts of sulphide of antimony, and directions are also given for the preparation of ferrochromium, ferromanganese, and ferrocerium.

The Victory of the Storage Battery.—One of the most encouraging features in modern central station operation, whether light or power, is the attention which is being paid to the running economies. It would be unfair, says the New York *Electrical Engineer*, to say that no attention had ever been paid to getting the last bit of energy out of the coal burnt under the boiler by some of our large operating companies; but it is certain that nine-tenths of the stations existing five years ago paid little attention to those so-called refinements which, as events frequently prove, make the difference between a dividend and a deficit. But these are the days of small things, and with them central station managers have come to understand that they can improve their balance sheet by other means than mere improvements in steam apparatus. They are gradually, but surely, coming around to the practice, long since in vogue in Germany, particularly, of operating their steam plants in connection with storage batteries. It would be a work of supererogation to rehearse at this late day all the advantages which the storage battery offers to the central station; the proof of the pudding is in the eating thereof. To carry out the metaphor, those who have tasted a good one want more, as shown by the fact that scarcely a single station has put in the battery that has not followed it up by one or more additional equipments. We are well aware that even some of the most progressive and intelligently managed companies in the country have held aloof from the storage battery, notwithstanding that New York, Boston, Brooklyn, Philadelphia, and other cities had put them to good use. Among these was the Chicago Edison Company, but we are now informed that this company has also fallen into line and, if we may judge by the size of its plant just ordered, is making up for lost time with a vengeance. This contract was referred to in the ELECTRICAL REVIEW, page 931 of our last volume. In this connection we note also the intention of the Buffalo Railway Company to instal accumulators to be charged from power obtained over the high tension lines from Niagara. As their load is a fluctuating one, and is particularly low during the night the battery will be able to absorb all the surplus energy available and thus permit the company to utilise fully the power for which they are paying. This battery, we understand, will also be the largest ever installed for railway purposes. The *Electrical Engineer* says it is gratifying to be able to note the growing popularity of this valuable station auxiliary.

The Central London Locomotives.—Once again information regarding the electrical equipment of the Central London Railway comes direct from America. The New York representatives of the daily papers telegraphed at the end of last week that the General Electric Company, of Schenectady, New York, have just received a large order for 32 electric locomotives for the Central London Underground Railroad. Owing to the size of the tunnel through which the underground trains will pass, these locomotives will be of a small pattern. They will have a capacity of 800 horsepower, and will weigh 45 tons, and will be able to draw a train of five cars weighing 150 tons at the rate of 15 miles per hour. Work on this order is to be begun at once.

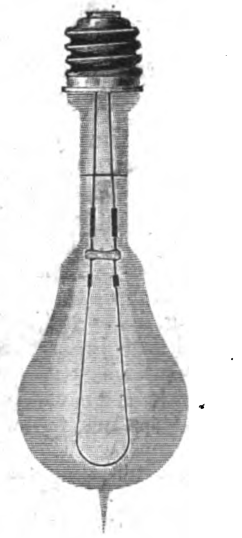
Lectures.—Mr. Wm. Lynd lectured on 20th inst. at the Grosvenor Hall, Belfast, his subject being "Wireless Telegraphy."

At the St. Michael's Working Men's Institute, Pelsall, on 15th inst., Messrs. S. Thacker and Bishop, of Walsall, lectured on "Experimental Electricity."

"Electricity a Transmitter of Power; its Application to Mining," was the title of a paper read by Mr. F. H. Headley, at Camborne, on 19th inst., to a meeting held under the auspices of the Mining Association and Institute of Cornwall.

Useful Reference Book.—"Clubs," a list of over 2,500 clubs frequented by the English in all parts of the world, for 1898, has just been published by Messrs. Spottiswoode and Co. The book is printed in tabular form, and gives much more information than in previous years; for instance, it notes the names of secretaries, dates of establishment, entrance fees and subscriptions, and has, in some cases, remarks on the qualifications for membership, &c.

A Renewable Incandescent Lamp.—Since no substance will probably ever be discovered which will stand a higher temperature than carbon, no improvement in the efficiency of the glow lamp is to be looked for by substituting other materials for the carbon filament. There is room, however, for a considerable reduction in the cost of renewals. The life of a glow lamp is limited, and usually before the filament is burnt out it becomes so wasteful of energy that it pays to replace it by a new lamp. At present the whole lamp is rejected when the filament only has been worn out. Herr Ch. Howard has designed a lamp on a more rational principle, in which the worn-out filament can be replaced, while the remaining parts of the lamp are still utilised. From the description of this lamp (*Zeit f. Elektro Heft* 23, 1897) it appears that the ordinary pear-shaped bulb has a tubular extension, to the end of which the socket is attached. (See fig.) The ends of the carbon filament are connected to two short lengths of nickel wire, which are held together by a glass crosspiece. The ends of these wires are pushed into two sockets fixed on the ends of another pair of nickel wires connected to the platinum terminals of the lamp. When it is desired to renew the carbon filament, the glass neck of the bulb is cut at the line shown in the fig., and the carbon filament is removed by pulling its nickel terminal wires out of the sockets. A new carbon filament is then inserted, and the parts of the glass bulb are placed in position and fused together. The bulb is then exhausted of of air in the usual way. This lamp has been patented, and is said to have already been proved to be a practical success.



The Alleged Failure in the Madrid Supply.—As we go to press, the following comes to hand from the secretary (Mr. Chas. Hill) of the Electricity Supply Company for Spain:—"In your issue of 21st inst. you publish a note from a Madrid correspondent, stating that at about the beginning of the present month the greater part of the district supplied by this company was without light for 48 hours. I shall be greatly obliged if you will kindly correct this statement, which is very much exaggerated. The breakdown in question, caused by an accident to the cables, affected only a comparatively small area, and the lighting was resumed the same evening, after only a few hours' interruption."

The Purchase of the Fowler-Waring Cables Company.—As we announced in our issue of January 7th, the Western Electric Company, Limited, have concluded arrangements with the Fowler-Waring Cables Company, Limited, of 110, Fenchurch Street, E.C., and North Woolwich, to take over their business as from January 1st, 1898. The notice is also confirmed by the Fowler-Waring Cables Company, who state that all debts due to them in respect of the business up to January 1st should be sent to the secretary, at 110, Fenchurch Street, and all debts and liabilities in connection with the said business incurred, accrued, or owing at the close of December 31st, 1897, fall to be discharged by this company.

The Electric Cab Mishap.—The daily press would seem to be short of matter just now, judging by the amount of attention given to the mishap with an electric cab in Fleet Street. It is not altogether the right thing to prejudice the general public against these vehicles before they have had a fair trial, but this seems a very likely result of some of the high-falutin and imaginative accounts which have been printed regarding, what is officially termed, the skidding of the hind wheels. The only damage to the vehicle seems to be the straining of one of these wheels, and the following day the cab was working as usual. The daily sensationalist made it appear that the cab was smashed to pieces, and half of Fleet Street ploughed up.

The Memorial to Ferraris.—We hear that the proposed memorial to the late Prof. Ferraris is receiving considerable pecuniary support from America, France, and Germany, but, though we say it with feelings of keenest regret, not one penny has been received from this country. It is to be earnestly hoped, for the honour of English science, that the occasion will not be allowed to pass without some appreciation being shown to the services which Ferraris had rendered to science.

New Paper.—On Tuesday next Messrs. Cordingley and Co. will bring out the first number of a new penny daily, called the *Daily Contract Recorder*.

Appointment Open.—The St. Helens Corporation want a resident electrical engineer for electric lighting and traction plant, at £200 per annum. See our "Official Notices" for particulars.

Improved Electric Glow Lamp Company v. Edison and Swan United Electric Light Company, Limited.—Yesterday in the Queen's Bench Division, before Mr. Justice Mathew, this case came on for hearing. It was an action to recover damages for breach of contract. The case for the plaintiffs was that by an agreement in writing in a letter from plaintiffs to defendants, of November 3rd, 1896, and in a letter from the defendants to the plaintiffs of November 9th, 1896, the defendants agreed to manufacture for plaintiffs 100,000 electric incandescent lamps of their own make, one-third to be round lamps, and two-thirds to be conical shaped. The defendants agreed to deliver a minimum weekly quantity of 2,000 lamps, delivery to commence within five weeks from the date of the acceptance of the contract. Plaintiffs alleged that defendants had failed to deliver the minimum quantity, by reason of which the plaintiffs, who were unable to purchase the lamps elsewhere, had been unable to carry on their business, and had lost the large profits they would have made out of the sale of the lamps, and had been greatly injured in their business. The defendants, in their defence, did not admit the contract, and alternatively they pleaded that if they did do so, they were prevented by the acts of the plaintiffs from delivering the lamps on the agreed dates. They had otherwise delivered all the lamps contracted for, and they denied that the plaintiffs had suffered any damage.—Mr. Bousfield, Q.C., M.P., Mr. Wallace, Q.C., and Mr. A. J. Walter, were counsel for the plaintiffs, while Mr. Fletcher Moulton, Q.C., and Mr. J. C. Graham represented the defendants. In the course of the case the defendants admitted that there had been delay in the delivery, and after consultation between the parties a verdict was, by agreement, entered for the plaintiffs for £750 and costs.

Dr. Cornelius Herz.—Dr. Cornelius Herz went out for a short drive on Saturday last, this being the first time he has left the Tankerville, Boscombe, for six years.

Personal.—Mr. Thomas H. Blakesley has resigned his seat at the Council board of the Physical Society. He is, therefore, no longer honorary secretary of that Society.

Lecture.—On 17th inst. a lecture on "Electric Currents, their Ways and Adaptation," was delivered in the Marine Engineers' Institute, King Street, South Shields, by Mr. G. Smith, of H.M. Customs.

New York Electrical Society.—Mr. S. Dana Greene read a paper before the above society, at New York, on the 10th inst., his subject being "The Relations Between the Customer, the Consulting Engineer and the Electric Manufacturer."

Storage Batteries for Buffalo.—An American Exchange says that in December the announcement was made that the Buffalo Railway Company would instal at once a set of storage batteries at its Niagara Street power station to act as a station auxiliary. There will be about 290 cells, which will be contained in a fireproof structure built especially for the purpose. The building will measure 40 feet × 70 feet, and the Buffalo Railway Company expects to have the installation in operation early in March.

The L.C.C. and Lantern Projection.—In some regulations which have just been issued by the L.C.C. respecting the uses of limelight in premises licensed by that body, we observe that the employment of ether and other inflammable liquids is forbidden, and it is suggested that in all cases where possible, the electric arc light shall be used as an illuminant instead of limelight.

Webb Testimonial.—The presentation dinner to Mr. and Mrs. Webb has been postponed to Monday, February 21st, owing to the rooms of the Hotel Metropole being required on the 14th (the date originally fixed) for a dinner at which the Prince of Wales is to be present. Early application for tickets should be made to Mr. H. Edmunds.

Fatality.—An inquest was held on Friday last at the St. Bartholomew's Hospital on the body of Herbert Mewcross, aged 25, a labourer, who was crushed to death by a crane at the Electric Railway Works, in Moorgate Street, on the 13th inst. The jury returned a verdict of "Accidental Death."

Electric Mail Carts.—It is stated that the Post Office on Monday last started a service of electric delivery vans between St. Martin's-le-Grand and Paddington Station.

James Watt Anniversary Dinner.—The 11th James Watt anniversary dinner, in connection with the Institute of Engineers and Shipbuilders in Scotland, took place at Glasgow last Saturday evening. Lord Kelvin was present, and in proposing "the memory of James Watt," made a very interesting speech.

Appointment.—Mr. Frank Clowes, on taking the position of chief chemist to the London County Council, has been elected Emeritus Professor of Chemistry of the University College, Nottingham.

Explosion at an Oldham Electrical Supply Station.—We take the following paragraph from yesterday's *Liverpool Mercury*. We have, however, been unable to verify this extraordinary statement:—"An alarming explosion occurred on Tuesday evening at the Oldham Corporation Electrical Supply Station, Rhodes Bank, and effected damage to the extent of between £200 and £300. At six o'clock a loud report was heard and the place was enveloped in steam. It was found that the cylinder ends of two engines, connected with dynamos, had been blown out. These lay smashed a few yards away, and one, weighing two tons, came very near striking Mr. Newington, electrical superintendent."

Sludge and Dust Destructors.—Yesterday a large number of professional gentlemen were invited to visit the Leyton Sewage Works for the purpose of inspecting the "Beaman & Deas" destructors, and to meet Sir Douglas Galton, K.C.B., D.C.L., &c., Chairman of the Council of the Sanitary Institute. A luncheon in the Town Hall followed, at which Sir Douglas spoke at great length on the subject of refuse destruction and the methods in use, but we must defer a detailed description of the Leyton plant till next week, when we hope to deal very fully with the matter. Sir Douglas Fox and Mr. Francis Fox, as engineers, with the assistance of Messrs. Stanger and Blount, consulting chemists and analysts, have given a most favourable report upon the apparatus as a most efficient and economical refuse destructor without injury to the neighbourhood.

NEW COMPANY REGISTERED.

Moutrie & Co., Limited (55,696).—Registered January 18th with capital £5,000 in £1 shares to acquire the business of Moutrie & Co., of 17, Berners Street, W., and to carry on the business of electrical and mechanical engineers, machinists, fitters, gas engineers, founders, wood and metal workers, electro-platers, &c. Registered without articles of association. Registered office, 17, Berners Street, W.

OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

Salisbury Electric Light and Supply Company, Limited (41,414).—This company's annual return was filed on January 8th, when 1,307 shares were taken up out of a capital of £20,000 in £1 shares. £1,013 15s. has been paid, and £293 5s. is in arrears.

CITY NOTES.

Bedford Lighting Accounts.

THE result of the year's working at Bedford discloses a loss of £1,200, which is a considerable increase upon that of last year, when the figure was £914. The net revenue shows a considerable increase, being, in fact, nearly £700 more, but if we take the whole of the figures on the debit side, the interest on mortgage debt accrued to date (£1,157), and the instalments of principal of money borrowed (£1,560), the undertaking will have to call upon the rates to the extent of £1,200. With a considerably increased output the cost of production shows only a small reduction. Probably the works are not yet obtaining the full benefits from the extensions of plant that have been made during the past 12 months.

The following table gives the cost per unit:—

	1897.	1896.
Total capital expended	£46,890	£38,670
Number of units sold	255,990	158,238
Number of lamps connected	—	—
Revenue from sale of current	£4,606	2,939
Net revenue	£1,593	£842
Average price obtained per unit	4·30d.	4·47d.

Cost of production.	£		Per unit.	1896.
Coal	1,322		1·24d.	1·35d.
Oil, waste, water and engine room stores	135		·13d.	·16d.
Salaries and wages at generating station	771		·72d.	·93d.
Repairs and maintenance of buildings, engines, boilers, dynamos, &c.	320	Works' cost 2·39d.	·30d.	·12d.
Rent, Rates and taxes	142		·13d.	·18d.
Management expenses, directors' remuneration, salaries of managing engineer, secretary, clerks, &c., stationery and printing, general establishment charges, auditors, law charges, and insurance	349		·33d.	·40d.
Depreciation of buildings and plant account	—		—	—
Renewal fund account	—		—	—
Total	£3,039		2·85d.	3·14d.

Revenue.	£	s.	d.	Average price obtained per unit.
By sale of current	4,606	0	0	4·30d.
Meter rents, &c.	—			—
Total	£4,606	0	0	4·30d.

Total cost per unit (exclusive of depreciation and renewal accounts), 2·85d.; works' cost, 2·39d.

Total loss on year's working, £1,200.

Direct United States Cable Company, Limited.

The forty-first ordinary general meeting was held on Tuesday at Winchester House, when Mr. E. M. Underdown, Q.C., presided. He stated that the revenue for the six months ended the 31st ult., after deducting outpayments, amounted in round figures to £50,098, while the working and other expenses, including income-tax, but exclusive of the cost of cable repairs, absorbed £19,723, leaving a balance of £30,375 as the net profit of the half-year, making, with the amount brought forward, £34,303, out of which two interim dividends of 3s. per share each for the quarters ended September 30th last and the 31st ult. had been declared, and £12,000 had been transferred to reserve fund account, leaving £4,090 to be carried forward. The revenue had continued to increase during the half-year, and was still improving. The increase in the past six months had been £2,497, or about 5½ per cent., as compared with the earnings in the corresponding period of 1896. The expenses in London remained practically the same, while those at the stations had been only slightly higher, consequent on the additional work done owing to the increased traffic. The remaining expenditure was more or less fixed, but, generally, it showed a small reduction as compared with that of the same period of 1896. The cable renewals in the past half-year had cost £8,325, which, with the amount written off the Ballinskelligs buildings account, £2,000, had been debited to the reserve fund account. On the other hand this account had been credited with £5,604 for interest on the investments and the £12,000 set aside, as he had already mentioned, out of revenue, leaving the balance of the reserve fund standing at the increased figure of £345,767. Many of their investments had recently increased in value, and during the past half-year they had been added to by £12,220, bringing the total up to £330,786 at cost. The present market value of the investments was about £385,800, showing a profit on their cost price of about £55,000. Their relations were most cordial with the allied companies, the Anglo-American and the Western Union Companies, and every kind of mutual accommodation was afforded between them. This company's share in the pool was very satisfactory, but he found that the advantages to the public from their combination were not generally understood. The public thus had the advantage of seven cables; and when traffic accumulated it must be manifest how well it could be dealt with, with this number of cables, owing to the arrangement between the companies. Moreover, when interruptions to the cables occurred, as must happen, the traffic was practically never suspended or interrupted. At the same time the independence of the companies was maintained—that was to say, any member of the public who chose to forward his message by the Anglo-American, the Direct, or the Western Union companies could do so, and this was done from time to time. It was true that the proceeds were shared among the different companies, but many people preferred one route to another. The short cable, as it was called, had been interrupted, and two repairs were made to it during the half-year. It had been thought advisable to put a considerable piece of new cable, 57 miles, into that part of the line which was in comparatively shallow water, and to move the cable into deeper water, where it was practically safe from damage from ships' anchors. He concluded by moving the adoption of the report and accounts. Sir James Pender, M.P., seconded the motion, which was carried unanimously; and at the instance of Captain Goodsall and Mr. John Newton, a suggestion was unanimously approved recommending the board to distribute an amount equal to 5 per cent. on the salaries of the staff as a bonus in celebration of the Diamond Jubilee year.

London Electrical Cab Company.

The directors of this company are offering for subscription an issue of 86,388 £1 ordinary shares, completing the issue of the £150,000 authorised nominal capital. The shares are offered at 2s. 6d. premium. The proceeds of two-thirds of the shares already issued were, by arrangement with the vendors, retained for working capital, and the balance of one-third only was paid to the vendors on account of the agreed purchase price (£50,000). The proceeds of the present issue will be similarly dealt with, so that the working capital will continue to be two-thirds of the total share capital issued.

Although the outlay up to date includes the cost of altering and adapting the extensive buildings in Juxon Street, Lambeth; also fitting up the same with electrical plant, machinery, &c; also all preliminary expenses and the cost of the cabs now on the streets, and parts of further cabs, the company still have at their bankers nearly half the working capital received.

A much larger number of cabs might have been placed upon the streets within the same period, but in the interests of the company it was decided to first practically test a smaller number.

Immediately the directors were satisfied as to these, contracts were placed for further cabs, which will have several very important improvements, and which, when completed, will absorb nearly the whole of the working capital at their disposal. These vehicles will be delivered as quickly as possible, and there will then be three times the number of electric cabs than there are now on the streets.

It is with the object of still further increasing the number of the company's vehicles that this issue is made.

With the prospectus is given a copy of a report by Messrs. Kincaid, Waller & Manville, dated January 17th, 1898, on the prospects of the company. The list closes to-morrow (Saturday).

House-to-House Electric Light Supply Company.

According to the *London Gazette*, the petition presented on January 13th, 1898, for confirming the following special resolution, will be heard on February 5th before Mr. Justice Romer in the Chancery Division:—"That the agreement dated November 29th, 1897, and made between the company of the one part, and the several persons, corporations and firms executing the same in the Schedule thereunder written (thereinafter called 'the holders of the founders' share') of the other part, be approved and confirmed, and that having regard to the terms thereof, the capital of the company be reduced from £200,000 divided into 40,000 shares of £5 each, of which 27,900 are ordinary shares, 12,000 are preference shares, and 100 are founders' shares, to £199,500 divided into 39,900 shares of £5 each, of which 27,900 are ordinary shares and 12,000 are preference shares; and that such reduction be effected by cancelling the whole of the said founders' shares; that is to say, the shares in the company numbered 1 to 100, both inclusive."

Gutta Percha Corporation.

The statutory meeting of this Corporation was held at Winchester House on Wednesday. Sir Edward Thornton, the chairman of the Corporation, after referring to the composition of the Board, pointed out that while the patent was lying idle in inexperienced hands, it had been worked by others in France where they had been producing as much as 140 lbs. per day. Of course they were not going to have their patents infringed in that manner, consequently they sent their manager to France, who inspected the works, and as a result of negotiations the French Company had agreed to hand over the factories on satisfactory terms. Pending the time, therefore, it would necessarily take to erect a factory in London, they would be in possession of a factory which was earning money. There would be no difficulty in obtaining leaves, their agents being prepared to supply thousands of tons per annum. After extracting the gutta from the leaves, they could be sold for paper pulp at a price which would cover cost of freight.

After the usual vote of thanks the meeting then terminated.

Central London Railway Company.

The report of the directors of the Central London Railway Company for the half-year ended December 31st last, to be submitted to the general meeting to be held in London on February 2nd, states that the expenditure during that period amounted to £460,728, which, added to the amount previously expended, makes a total outlay to date of £1,606,948. The sum of £228,448, which appears in the accounts as owing to the contractors, is due to them for work done as certified by the company's engineers. The latter report that satisfactory progress has been made with the works during the half-year, and that at the present time three-fourths of the main line tunnels, one-half of the station tunnels, and nearly the whole of the lift and staircase shafts have been constructed. At the Bank Station, the very difficult work in connection with the subway for pipes is complete, and the public subways are in an advanced stage.

Anglo-American Telegraph Company, Limited.—The directors, after placing the sum of £12,000 to the credit of the renewal fund for the half-year, have resolved to recommend at the meeting on February 4th next, the declaration of the following dividends:—(1) A balance dividend of 19s. 6d. per cent. upon the ordinary consolidated stock for the year ending December 31st, 1897; (2) a balance dividend of £1 19s. per cent. upon the preferred stock for the year ending December 31st, 1897, both payable on February 5th next, less income tax, to the stockholders registered on the books of the company on the 21st inst. After paying the foregoing dividends, there will be a balance of about £200. The above dividends, together with those already paid, will amount to £3 per cent. on the ordinary consolidated stock and £6 per cent. on the preferred stock for the year 1897. The register of transfers will be closed from January 22nd to February 4th, both days inclusive.

Stock Exchange Settlements.—The Stock Exchange Committee has appointed Wednesday, February 2nd, a special settling day in Edison & Swan United Electric Light Company, Limited—£194,023 4 per cent. debenture stock, and has ordered the undermentioned securities to be quoted in the Official List:—Commercial Cable Company—Further issue of £264,711 sterling 4 per cent. 500-year debenture stock. Edison & Swan United Electric Light Company, Limited—£194,023 (part of £200,000) 4 per cent. debenture stock.

Applications have also been made to appoint a special settling day in, and to grant a quotation to:—City of London Electric Lighting Company, Limited—Further issue of 10,000 ordinary shares. Electric Construction Company, Limited—4 per cent. perpetual first mortgage debenture stock, and a further issue of 8,657 7 per cent. cumulative preference shares, and to allow to be quoted in the Official List:—City and South London Railway Company—Further issue of 832 5 per cent. perpetual preference shares, Nos. 8,420 to 9,251.

The Electro-Chemical Company, Limited.—An issue of £30,000 5 per cent. first mortgage debentures of £100 each is announced. The debentures are secured by a first charge on the freehold property and British patent rights of the company, the value of the property alone, exclusive of goodwill or patent rights, being estimated at £73,100. The debentures are redeemable on July 1st, 1910, at par, or they may be redeemed, on six months' notice, at £105.

Venezuela Telephone and Electrical Appliances Company.—Coupon No. 15 of the 5 per cent. mortgage debentures, due on 31st. inst., will be paid from that date at the Capital and Counties Bank, Limited, 39, Threadneedle Street, E.C., and at Messrs. Westendorp & Co.'s Bank, Amsterdam.

TRAFFIC RECEIPTS.

The City and South London Railway Company. The receipts for the week ending January 23rd, 1898, were £1,075; week ending January 24th, 1897, £1,114; decrease £39; total receipts for half-year, 1898, £4,384; corresponding period, 1897, £4,387; decrease, £53.

The Cuba Submarine Telegraph Company. The receipts for the month of October were £2,885, as compared with £4,314 in the corresponding month of last year.

The Liverpool Overhead Railway Company. The receipts for the week ending January 23rd, 1898, amounted to £1,354; corresponding week last year, £1,217; increase, £137.

The Western and Brazilian Telegraph Company, Limited. The receipts for the week ending January 21st, 1898, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,011.

WHAT IS THE FATAL E.M.F.?

By W. S. HEDLEY, M.D.

Four recent cases of death from accidental contact with electric lighting wires carry the mind back to the Board of Trade Inquiry which resulted in raising the limit of low pressure supply. It may be remembered that one gentleman present at that inquiry asserted that he had felt no ill effects from a 600-volt shock. The present writer commented on that statement in the following words*:—"Did he touch one pole only of a 600-volt circuit? If so, what was the earth insulation of the other pole? Was his body in contact with the earth, or, presuming that he simultaneously placed one hand on each pole of the 600-volt circuit, what was the surface area of skin contact and what was the condition of the skin? In the absence of information in these points the statement referred to cannot be considered to have any real value."

The four fatal cases above referred to are reported in the *Elektrotechnische Zeitschrift*, December 30th, and occurred in a chemical factory, the name of which is withheld. The first case was that of a man whose business it was to raise and lower an arc lamp by means of a wire rope, windlass and iron crank. He had instructions never to attend to the lamp excepting when standing insulated on a wooden stool. Instead of this he stood with bare feet upon the ground. Having accidentally forced up the lamp too high its support was bent and touched an upper pulley, in consequence of which a current at 115 volts was communicated to the cable, the windlass and the crank, and proved fatal to the man. In the second instance a labourer, contrary to instructions, seized an alternating current conductor which was outside a window. In the third case two insulated wires were enclosed in an iron tube, and it happened either that one of the joints of the tube getting loose, cut the insulation of the wire, and so the wire and tube were brought into contact, or that a wire having become unscrewed its end came into contact with the unearthed pipe, and the fatal shock was received from the latter. In the fourth instance a faulty flexible conductor or lamp fitting seems to have been the cause of the accident. In at least three of these cases a good contact and considerable contact area had evidently been obtained by firmly gripping the conductor—the contact was probably of some duration—a most important factor in producing fatal results, the skin resistance of the hands had probably been much reduced by handling chemicals, by the dampness of the place, or by processes carried on in the factory; and when to these circumstances it is added that the labourers not being provided with dry boots were in the habit of going about on a damp floor with wooden slippers or with bare feet, it is evident that every condition had been secured to enable the available electromotive force to pass a large current through the body.

What is the minimum fatal electromotive force? This has yet to be defined, and with the definition must come also a statement of the necessary conditions. Nature, area and duration of contact, condition of skin, maximum electromotive force, periodicity. The question is complex, but in the opinion of the present writer everything seems to point to the fact that all commercial forms of electric lighting currents, varying as they do from 80 volts upwards, are dangerous to human life under certain conditions. Fortunately the required conditions do not often occur in actual practice, and when they do occur they admit of remedy.

* "Current from the Main." Lewis & Co., London.

Such cases as the above would be met by a concentric system of wiring with the outer conductor earthed and with switches, &c., on the inner.

WINDINGS OF POLYPHASE ARMATURES.*

By J. P. STONE.

(*Concluded from page* 70.)

Regarding choice of winding, in some cases, undoubtedly, one is preferred to the other. In such cases as with

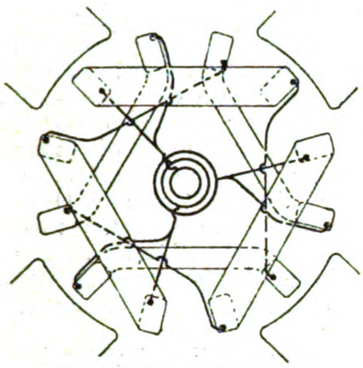

Fig. 9.—Delta Winding.

alternators where rectified current is used for compounding, the Y-connection adapts itself more readily, as the commutator can be connected in the common junction of the three phases. The delta winding, however, is essential in generators which shall combine direct-current output or input, with alternating current output or input, such as a rotary converter, where, on account of the direct-current feature, the winding must be of the delta form; that is, must be continuous, as shown in fig. 5, which represents a continuous winding tapped off at three points 120° apart. Furthermore, by the choice of one or the other it is often possible to make a decidedly better motor, both mechanically and electrically.

An armature designed for a given working voltage measured between the lines, would, if planned for Y-connection, have fewer turns of larger wire than if intended for delta connection. This is sometimes convenient, and is use-

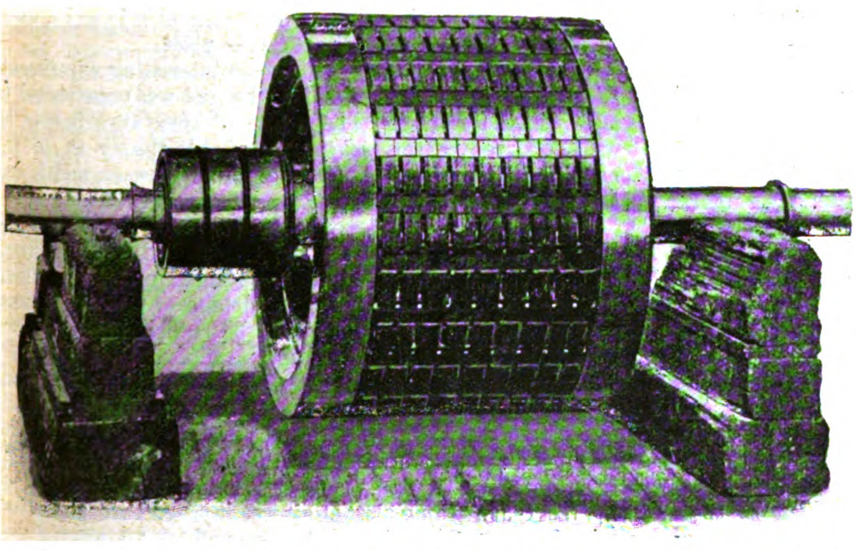

Fig. 10.—Polyphase Armature.

ful in keeping the voltage between coils low. The delta connection, on the other hand, has more turns of smaller wire, as the current is diminished while the E.M.F. in each coil is the full E.M.F. between the lines. This property is useful under certain conditions, as it makes the E.M.F. between any two lines somewhat less; for instance, in a machine with very large currents, the delta winding would be preferable, since in that winding the current in each wire is smaller than the line current (the line current being supplied from two phases as illustrated in fig. 5). The contrary

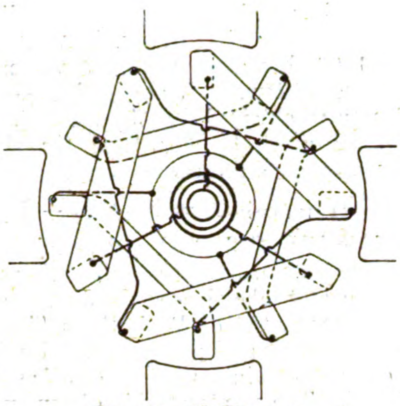

Fig. 11.—Y Winding.

is the case in a machine for very high potential; it is often possible to get a simple winding by a Y-connection, since then the number of turns necessary to give the requisite voltage are less than those in a delta-connected winding.

The same winding can, of course, be connected Y or delta according to the dictates of convenience, as in figs. 9 and 11, which show the same armature connected delta and Y respectively. Thus it will be seen that the manner of connecting the windings of a multiphase armature is largely a matter of convenience, and thus does not influence the working of the machine.

A completed armature for a polyphase generator is shown in fig. 10, the winding and connection of which are covered by a shield at each end to protect them from injury.

* *American Electrician.*

THE JACQUES CARBON CELL.

The Jacques carbon cell, which was some time ago described in the Electrical Review,* has recently given rise to interminable discussion in the American technical journals. It may be necessary to remind our readers that this cell consists of an iron pot, containing caustic soda or potash, which is kept in a fused condition by the application of external heat. A rod of carbon is immersed in the fused alkali, and a current of air is forced into it in such a way as to come in contact with the surfaces of the electrodes.

The original theory of the inventor appears to have been that the air forced into the electrolyte combined with the carbon, in such a way that the energy of combustion was transformed into electric energy, that the carbonic acid gas produced by the combustion escaped in bubbles, and the electrolyte remained practically unchanged. Taking into account only the carbon consumed inside the cell, Jacques calculated that the efficiency of his generator was 82 per cent. A subsequent calculation, in which the carbon consumed in heating the pot was taken into account, reduced the first sanguine estimate to 32 per cent.† A letter by Mr. C. J. Reed in the *American Electrician* for this month, shows that the efficiency of the Jacques "generator"

* Vol. 38, p. 826.
† Electrical Review, Vol. 39, p. 802.

must undergo a still further reduction; that, in fact, the raw material or fuel consumed by the Jacques cell will cost at least 34 times as much as that required by a steam engine doing the same amount of work.

The serious blunder made by Jacques and his supporters lay in the assumption that carbonic acid gas arising from the combustion was given off in the gaseous condition, and did not combine with the caustic alkali. The correct theory (as far as it went) of the reactions in the Jacques cell was given by Mr. Fitzgerald in the ELECTRICAL REVIEW, Vol. 39, p. 10, July 3rd, 1896, but at that time it was neglected by the American investigators, as it appeared to contradict the experimental results obtained by Jacques. The electro-chemical equation given by Fitzgerald for the Jacques arrangement "so far as it constitutes a voltaic cell," was

$$2\,(Na\,HO) + C + O_2 = Na_2\,CO_3 + H_2\,O. \quad (1)$$

Prof. Ostwald and Mr. C. J. Reed, with certain reservations, agree in accepting this equation as representing the electro-chemical reactions that take place in the Jacques cell.* It is now stated, on the authority of Prof. Elihu Thomson, that the whole of the carbonic acid gas produced by the combustion of the carbon combines with the caustic soda to form carbonate of soda. The result of this discovery is that the Jacques cell is as much a means of getting electricity direct from potash or soda as "direct from carbon."

Taking into consideration the whole of the materials consumed in the production of electric energy, Mr. Reed makes the following rough estimate of the comparative cost of energy produced by the Jacques cell and a steam engine.

"Leaving now the question of efficiency for the more important question of commercial economy, we find that if the carbonate is formed, instead of the carbon dioxide, the battery ceases to have any possibilities. Its use would mean the displacement of a steam engine, using for each H.P.-hour $1\frac{1}{2}$ lbs. of coal, worth \$3 per ton, by an apparatus using $2\frac{1}{2}$ lbs. of caustic soda, worth \$60 per ton, in addition to ·36 lb. of coal, worth \$3 per ton, and ·24 lb. of carbon in sticks, worth at least \$20 per ton. The comparison is, for raw material alone, or fuel,

Steam engine ...	...	...	... \$·00225 per H.P.-hour.
Jacques battery:—			
Caustic soda ...	... \$0·075		
Coal ...	...	·00054	
Carbon	...	·0024 ...	·07794 " "

"The raw material for the Jacques battery will cost at least 34 times that for a good steam engine, and about 75 times that necessary for a gas engine. The weight of raw material to be handled for the Jacques battery is more than twice that used in the steam boiler, and the residue or 'ash' from the battery would weigh 10 or 12 times as much as that from the boiler. The figures are based on using 60 per cent. caustic soda, which would probably be the cheapest material that could be used."

Mr. Reed considers that the net efficiency of Jacques cell must be put at 8 per cent., when allowance is made for the power required to drive the air pump.

Though Prof. Ostwald and Mr. Reed agree as to the nature of the electro-chemical reactions which take place in the the Jacques cell, they differ *in toto* as to the source of the E.M.F. which propels the current through the battery circuit. Prof. Ostwald considers that the operation of the Jacques element is exactly analagous to that of the Lalande element, which consists of copper oxide and zinc, immersed in sodium hydrate. This cell has an E.M.F. of 0·8 volt, and under the action of the current, the zinc dissolves, forming sodium zincate, while the oxide of copper is reduced to copper. The cell becomes exhausted as soon as any one of the three substances, zinc, copper, and sodium hydrate is used up. In case all the oxide of copper is reduced to copper, the cell can be restored to action by exposing the plate to air so as to re-oxidise the porous copper.

In the Jacques cell, the *rôle* of the zinc is played by the carbon; the *rôle* of the oxide of copper by ferric oxide or sodium ferrate. "The cell," says Ostwald, "will work until one of the three necessary constituents is exhausted. Since in the Jacques arrangement ferric oxide is the constituent present in smallest quantity, the activity of the cell depends entirely upon the renewal of the exhausted ferric oxide; *i.e.*, upon the amount of air or oxygen conveyed to the iron cathode."

Ostwald points out that the energy set free by the combination of the oxygen with the iron in the Jacques cell, is lost as far as the electric process is concerned. There is practically no way known, as yet, for preventing this loss.

The analogy between the reactions in the Lalande cell and the Jacques cell suggested by Prof. Ostwald is fully admitted by Mr. Reed, and from this analogy he deduces the full and complete equation of the Jacques cell, which, as we shall see, was only partially represented by the Fitzgerald equation given above. The reaction in the Lalande battery is

$$Zn + 2\,Na\,OH + CuO = Na_2\,ZnO_2 + H_2O + Cu \quad (2)$$

and that of the Jacques battery

$$3C + 6\,Na\,OH + 2\,Fe_2\,O_3 = 3\,Na_2\,CO_3 + 3\,H_2O + 4Fe \quad (3)$$

This latter equation shows clearly that the oxygen which passes through the electrolyte and oxidises the carbon, is derived from the oxide of iron and not directly from the oxygen which is blown into the fused alkali. The Fitzgerald equation does not make this quite clear, since taken without qualification, it means that the oxygen of the air is directly used for combustion of the carbon.

Notwithstanding the fact that Prof. Ostwald understood and stated clearly this important point, he uses the Fitzgerald equation to calculate the E.M.F. of the Jacques cell, from the heats of combination of the compounds represented by the equation. He obtains by this calculation a positive E.M.F. of 2·66 volts.

Mr. Reed calculates the E.M.F. of the Jacques cell from equation (3), and finds that the sum of the formation-heats of the reagents in the left-hand side of the equation exceeds the sum of the formation-heats of the products in the right-hand side of the equation. This means that the reactions in the Jacques cell will not generate an electric current, but that they will require an electric current generated by an external electric force to bring them about.

Mr. Reed's theory is that this external electromotive force is thermo-electric,* and, in short, he considers that the Jacques cell is a thermo-electric battery, not a voltaic battery. Ostwald asserts that it has been shown by Bouty and others that the thermo-electric forces between metals and electrolytes are very small, and that therefore there is not the slightest ground at present for the assumption made by Mr. Reed of the existence of large unknown thermo-electric forces between metals and electrolytes. But Mr. Reed has certainly scored a point by showing Ostwald that out of his own mouth he has condemned himself; and Mr. Reed may well ask where the E.M.F. comes from, if it is not thermo-electric. Reed's well-known experiments, in which he obtained a higher E.M.F. by substituting iron for carbon in the Jacques cell, appear to indicate the existence of considerable E.M.Fs. where no electro-chemical reactions can take place.

Mr. Reed has recently made some interesting experiments with a Jacques cell, in which the pot was constructed of silver instead of iron. The results of these experiments, he considers, proves the correctness of his theory as to the existence of large thermo-electric forces between metals and electrolytes. Describing these experiments Mr. Reed says†:—

"I have also found experimental proof of the correctness of this theory in a Jacques cell constructed of pure silver, instead of iron. The results were entirely different from those obtained with iron. The details of this experiment will be published later. It will be sufficient to say here that with the silver apparatus and pure caustic soda, metallic sodium was given off from the walls of the crucible and burned with explosive reports in 12 minutes after the circuit was closed, and the crucible had become alloyed with metallic sodium. The liberation of metallic sodium increased from that time until the end of the experiment, notwithstanding the fact that a strong blast of air was injected through a silver tube into the electrolyte. At the end of 20 minutes the potential of the cell had fallen to zero and reversed. In 30 minutes after the closing of the circuit, the explosions from the combustion of metallic sodium became so violent that the operation had to be stopped, and the room (a large one) was filled with a white cloud of dust of sodium oxide. The crucible was $1\frac{1}{2}$ inches in diameter and 3 inches deep. The

* *American Electrician*, January, 1898.

* ELECTRICAL REVIEW, Vol. 39, p. 350.

† *American Electrician*, January, 1898, p. 20.

carbon rod was ½ inch in diameter. The lower part of the crucible was found to be so thoroughly impregnated with metallic sodium, that it became spongy on washing with water. Water, which was afterwards allowed to stand in it, soaked through it in 24 hours, as it would through porous earthenware. On slight pressure the bottom of the crucible crumbled to powder, resembling a brittle amalgam of zinc.

"The reduction of sodium requires a much greater absorption of energy than that of iron, and its reduction cannot be explained on any theory except that of absorption of heat and the agency of a powerful thermo-electric current."

Whatever may ultimately turn out to be the correct theory of the Jacques element, it has now undoubtedly been shown to be commercially worthless.

ELECTRIC MOTORS ON THE NEW YORK ELEVATED RAILWAY.

According to the *New York Sun*, of January 11th, 1898, Mr. George Gould has authorised the publication of the following statement:—

"We have decided to introduce electricity on the elevated system, and we will now proceed to effect a general installation with as little delay as possible. I wish it understood that we purpose to work energetically along the lines indicated in Mayor Van Wyck's message, and leave nothing undone to adapt our accommodations in the fullest possible degree to the requirements and comfort of the public."

The full meaning of this announcement from the President of the Manhattan Railway Company may, perhaps, be gathered best from that part of Mayor Van Wyck's message to which Mr. Gould refers. Mayor Van Wyck, in speaking of the rapid transit problem and its solution, said:—

"You should demand and insist upon the substitution, in the place of the present motive power, of electricity, which can now be safely utilised in the operation of these roads, affording a more cleanly and less noisy service, and that, too, with an improvement in speed; and, again, the number of through express trains should be considerably increased, their running time improved, and their use continued throughout the day and night, and not, as now, restricted to a few hours in the morning and evening.

"The trunk elevated lines should be so extended as to furnish more convenient communication with the ferries, and, most important of all, these lines should not be confined through the greed or indifference of the corporations operating them to the thickly populated and therefore profitable residence and business districts. The corporations should be compelled to continue the present routes to the more sparsely settled and more distant localities, even if for a time some loss is entailed by so doing.

"It is essential to the prompt relief sought by the people that the time allowed for the completion of the improvements here suggested should neither be unreasonable nor unlimited. A definite period should be fixed, within a fair and sufficient limit, compelling promptness in the beginning and vigorous prosecution to the end of the work; and a bond of full proportions should be exacted to guarantee that the time limit would not be exceeded."

Mr. Gould's announcement indicates that no action on the part of the Municipal Assembly is needed to give New York its much needed facilities for travel through the only practicable means—the extension and improvement of the service of the elevated roads. The change in motive power which Mr. Gould promises will require the approval of only the State Railroad Commission, and there can be no doubt but that this can be secured. It is within the power of the managers of the system to provide for running faster trains and more express trains, and the increased speed is one of the earliest benefits which will arise from the use of electricity instead of steam motors. So long as the Rapid Transit Railroad Commission exists, it may put barriers in the way of additions and extensions of the elevated railroad lines. Such extensions and improvements require the approval of this Commission, and its approval has been withheld heretofore from such changes as the road has applied for permission to make, except upon terms which were not satisfactory.

People who travel across the Brooklyn Bridge know what a success the electric motor cars have been there, and how much they have added to the comfort and efficiency of the bridge car service. The substitution of electricity for steam has freed the bridge stations from the noise, steam, smoke and gases of the steam locomotives formerly employed. When the steam motors disappear from the elevated railroads, these annoyances will go with them. With the steam motor there will also disappear a considerable part of the noise which the running of trains now makes. Electric motors run with a true rotary motion, and produce no vibrations either in the car or upon the rail structure. For this reason higher speeds can be attained than are safe with the steam motor and its engines. Electric cars have been run at speeds between 80 and 100 miles an hour. At such speeds an ordinary locomotive would be apt to jump itself off the track. Every vibration saved in the engine means just so much less transmitted to the track, and turned into noise by the shaken structure.

It is going to be a great piece of work to instal electricity as the motive power for the elevated railroad system. There is no road in the world which is called upon to do such an amount of work, to carry so many passengers, to run so many cars and trains, and to make such a train and car mileage as the elevated system. In a single year the cars on the four elevated roads and the suburban line run 44,000,000 miles. In every day of 24 hours there are 3,500 trains despatched upon those lines, and 330 locomotives are kept in service for the work. Each of these locomotives is capable of exerting from 200 to 250 horse-power, and a fair estimate of the total average power needed to operate the road, according to General Manager W. J. Fransioli, is about 75,000 horse-power.

The installation of a plant or plants to supply this power will be the biggest enterprise of the kind that has ever been undertaken. Whether the whole amount of the power will be produced at one station or whether a number of stations will be built at convenient points along the lines, has yet to be determined, for this will depend upon a comparison of the cost of the enormous copper conductors which would be required to distribute the great currents to be employed and the cost of separate power plants. It is probable that several plants will be built at points convenient for receiving the great quantities of coal needed. At the present time the road burns in its locomotives 200,000 tons of coal a year. There will probably be a saving of one-half of this fuel at once by the more economical production of power in great stationary boilers and engines.

There is little doubt that the system adopted for supplying the electric current to the motors of the trains will be the third-rail method. For supplying the heavy currents required the overhead trolley is not suited, and the third rail system, as it is used on the Brooklyn Bridge and on the Chicago elevated roads, is a success. The next question which the engineers will have to settle is whether the trains shall be drawn by separate electric locomotives, like those used in the Baltimore tunnel and the one just put into service on the Hoboken Junction road, or by motor cars, such as are used on the Brooklyn Bridge. There is a third method of applying electric power to railroad trains, which is in use upon a road in Chicago. This is the Sprague unit system, under which each car on the road is provided with motors and controllers. Each car can be run separately, like a trolley car, or, by means of a system of wiring, the cars can be hitched together in any numbers, and the whole train operated from any car. Where the traffic varies very much in different parts of the day, and is subject to large fluctuations from day to day, this method has decided advantages, but on the elevated roads here, the general manager says, the traffic is very steady. The system, therefore, will probably not be adopted, and there are good reasons for believing that separate electric locomotives will not be used. It is probable that in place of the 330 steam motors, an equal number of motor cars will be used. Motor cars, like those now in use on the bridge, but with the motors wound to produce much higher speed, would be powerful enough to draw the trains on the elevated roads. Each of the bridge motor cars has four motors, each of 62½ horse-power, or 250 horse-power altogether.

To people living away uptown the most important improvement that will come with the introduction of the electric motors will be the saving in time which can be made. This will come from the ability of the electric motor to get up speed faster than the steam engine. In experiments made recently upon the two-mile experimental track of the General Electric Company at Schenectady it was found possible to attain a speed with the electric motors of more than 40 miles an hour within 20 seconds. In the same time one of the steam motors of the elevated roads would not have attained one-half that speed. It takes 40 minutes to go from the Battery to 129th Street by either the Second or the Third Avenue Road, making 25 intermediary stops, and 42 minutes and 49 minutes respectively to go from the Battery to 155th Street by the Ninth and the Sixth Avenue Road. The electrical experts say that one-third of this time could be saved by using electric motors, and a conservative estimate is that ten minutes could be saved on each trip without reducing the time now spent in taking on and letting off passengers. With a like saving of time on the suburban road, on which it now takes 17 minutes to run from 129th Street and Third Avenue to 177th Street, the entire trip might be made in about 43 minutes instead of 57.

Another advantage which would probably come from the change of motive power would be the running of two-car or three-car trains at night, at short intervals, instead of the regular four or five-car trains at intervals of 10, 15, or 20 minutes. This could be done with economy to the company and to the great advantage of the passengers.

The change of motive power will cost millions of dollars. Estimates which have been made have varied from $7,000,000 to $10,000,000. One considerable item of loss will be the putting out of service of the present motors. Each of these cost about $5,000, or $1,650,000 in all, and could not be replaced to-day for less than $1,000,000; yet it is likely that they will prove so unsaleable as to be almost a total loss. The elevated railroads of Chicago now have a large number of steam locomotives for sale and customers for them are few. To offset this loss, however, is the economy of maintaining an electric plant. It costs about 2 cents for repairs for each mile that a locomotive runs on the elevated roads, or $200,000 a year for 10,000,000 miles covered by the locomotives. Probably one-half of this sum would suffice to keep the necessary electric plant in order.

ELECTRIC TRAMWAYS IN GERMANY.

The *Elektrotechnische Zeitschrift* of January 6th, publishes several pages of tabular matter relating to existing electric tramways in Germany, and to those lines either in course of construction or which have been definitely decided to be carried out. In a summary of these tables reference is made to the towns equipped with electric tramways during the present decade, the figures given in the following representing the number of towns so situated at the close of the years mentioned.

Year.	Towns.
1891	3
1892	5
1893	11
1894	20
1895	32
1896	44
1897 (September)	56

In addition to the 56 instances cited for September of last year, there were 34 other towns at the beginning of that month where electric tramways were either in progress or finally decided upon, whilst in 30 other towns extensions of existing lines were either being carried out or were projected. At the close of 1897 eight of the lines promoted in the 34 towns in question had been completed, so that on January 1st, 1898, no less than 64 towns were in possession of electric tramways.

The following figures indicate the general position on September 1st, 1897:—

Length of lines, in miles, whether single or double track	593
Mileage of track	840
Number of motor cars	2,255
„ trailers	1,601

The total output of the electrical plant (except accumulators) required for the operation of the tramways amounted, as far as given by the tables printed by our contemporary, to 21,465 kilowatts. If, however, we assume an average of 21·7 kilowatts per kilometre of track for those lines where no information was forthcoming as to the machinery power—this average being based upon that of the following table—the total performance of the plant is increased to 24,920 kilowatts.

The table gives the name of the town, the maximum gradient in percentages, the kilowatts required per kilometre of track, and the number of kilowatts per motor car:—

	Maximum gradient in percentages.	Kilowatts per kilometre of track.	Kilowatts per motor car.

Türkheim-Wörishofen	4	11·7	35·0
Wiesbaden	5	63·1	28·6
Average	—	21·7	14·6

Our contemporary, in discussing these statistics editorially, states that they have been drawn from official sources, and mentions incidentally that many months, and at times even years, elapse between the promotion of a tramway scheme and the inauguration of the line, owing to the tardy manner in which it is possible to conclude negotiations with municipal and the State authorities.

It is specially noteworthy that during the past year some of the largest towns in Germany, namely, Berlin, Frankfort-on-the-Maine, Cologne, Konigsberg in Prussia, and Munich, have resolved to completely abolish the use of horses for tramway purposes, and have authorised the substitution of electric traction on all the tram lines in those towns. In addition to these, various important industrial districts are more and more endeavouring to connect up the localities by means of electric tramways, both for passenger and goods traffic. Among these may be mentioned the districts of Aix-la-Chapelle, Dusseldorf-Vohwinkel, Elberfeld-Barmen, Bochum-Gelsenkirchen, Gladbach-Reydt, Werne, Essen-on-the-Ruhr, the Saar locality, and the mining districts around Beuthen and Kattowitz in Upper Silesia.

Referring to the above table of powers required per kilometre of track and per motor car, our contemporary points out that both averages indicate in general a better utilisation of the generating plant. Thus, for instance, the average of 21·7 kilowatts per kilometre of track compares with 25·6 kilowatts in the previous year, this difference being mainly due to extensions of existing lines. The kilowattage per motor car of 14·6 is almost the same as in the previous year, when the average per car worked out at 15 kilowatts.

The overhead wire method on different systems is almost exclusively used on the German tramways, and only short lengths of line in Berlin and Dresden are worked with power supplied from underground conductors. Accumulator cars are used on the following lines: Charlottenburg-Berlin, Eckesey-Hagen in Westphalia, Frankfort-on-the-Maine, Gallluswarte railway station, Hagen-Kückelhausen-Haspe, Ludwigshaven-on-the-Rhine, Untertürkheim-Kornwestheim, and partly in Hanover. Mixed systems of working with overhead wire and accumulators, the latter being charged from the trolley wire during the journey over the trolley section, are used largely in Hanover, and to a small extent in Dresden. It is, however, proposed to introduce this method of working on the lines of the Grand Berlin Tramway Company in Berlin, and those of the Halle Tramway Company.

SOME AMERICAN METHODS.

Seeing that English employers are likely soon to be in a position to put into practice the advice of Mr. John Burns to follow American methods, which same advice seems to have been given in complete ignorance that it was in doing this that all the trouble of the strike arose, a few notes from *Machinery* on the way work is done in Cincinnati may be of interest. Cincinnati is supposed by a stretch of courtesy to be somewhat western, but we in England are apt to look further west than Cincinnati for our ideas of the west. The correspondent of *Machinery* has been calling on some of the works, and has made notes on some of the things he has seen.

At the Cincinnati Milling Machine Company's works, a three-floor building of nearly 30,000 square feet of floor space—a building, say, 200 feet × 50 feet—nothing is made but milling machines and cutter grinders, and 140 men are employed. The system is to have a casting storage room, and here all castings are received and kept in suitable bins. The paint shop is 70 feet × 20 feet, and here five men do the painting for the establishment, the room having steam coil and hot air pipes for use in the different weathers, variously to warm or cool the room and to dry paint. Another room is the stock storage room, which contains a centering and countersinking machine to prepare pieces for the shops.

The shop is replete with special devices for economical manufacture. The machine for cutting the dials of the milling machines takes in from 2 to 14 inches diameter, and finishes in three minutes a dial with 300 divisions. Every movement seems provided for, and bevil-faced dials are as easily cut as plain ones. At 100 strokes per minute, of any length, the graduations can be anything from 1 to 360. Then there is a special device for turning up the ⊥ slots in the cross slides of the machines, both in and outsides on both undercuts being done at one operation.

The holes in the bases of this company's machines are tapped. This is for moving purposes. Carrier trucks are in the form of a U, and have four suspension screws, which enter the tapped holes. The machine is thus lifted and wheeled off in a moment.

In the Egan Machine Tool Company's shop the floor space is 130,000 feet. On the unfinished parts of castings awaiting machining, are to be noticed small labels, thus—

Charge all time on this job to		
2,834	Screw machine Rot.	37

a device very much simplifying the entering up of time, which seems to be so great a difficulty in many shops.

A multiple planer tool is used for roughing off the sides of planer tables. It has six cutters, and finishes a side when it has been fed simply the distance of the cutter centres. Lathe V's are finished by a large V-tool at one full width cut. It leaves the surface nearly equal to a scraped surface, all jigs and fixtures are kept in proper places in cupboards. When the door is opened the electric light is turned on to permit correct and rapid finding of the tool. Forming tools are tested for form, before being hardened, upon a bar of Babbitt metal, when any inaccuracy can be corrected. Samples of all work done are kept in the grinding room to show the men what class of work is expected from them, each sample with its own particular place in the automatically lighted cupboard with a pair of buckskin gloves to be used in handling. We wonder if Mr. John Burns knows of this when he calls for American methods, and if he is disposed to still recommend them, and to advise the members of the A.S.E. to give their aid in advancing such a system if asked to do so. We propose to return to this subject.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

ABSTRACT OF INAUGURAL ADDRESS.

By J. W. Swan, F.R.S., President.

Sixteen years ago, I had the honour of bringing under the notice of the Society of Telegraph Engineers the question of a new mode of electric illumination by means of incandescent lamps. When the gas was lowered, and the current was turned on, there was an audible expression of surprise as the lamps lighted up; and when, after a breathing space, it was realised that the room was for the first time entirely lighted by incandescent lamps, the manifestation of satisfaction was, I remember, very strongly pronounced.

That occasion marked, in an emphatic manner, the beginning, or almost the beginning, of a movement that has gone on with increasing activity, until now it may be truly said that a great revolution in the means of producing artificial light for common use has been accomplished, a new and profitable industry has been created, and, incidentally, an impulse and inducement given to the larger and more general utilisation of electricity. I am looking back, and are such universally familiar objects now. Sixteen years is not a long time in the history of industrial evolution, and yet what changes have occurred in the last 16 years! The entire space is crowded with electrical invention and electrical work, not confined to electric lighting, but extending over the wide and varied fields of electrical power transmission, electric traction, and electro-chemistry. The successful introduction of electric lighting, and the great incidental improvements made in the machinery for transforming dynamic energy into electric energy, gave the impulse required to produce the immense activity that we witness to-day.

The domain of electrical engineering has broadened. When this Institution was founded, telegraph engineering was its principal feature; later, there grew up the new branches of electric lighting, electric traction, and the electrical transmission of power. These have so flourished that, if they have not overshadowed the older branch, they have at least sheltered and supported it; and there is another branch vigorously growing and giving promise of immense enlargement—that of electro-chemistry.

This brings me to a subject of great interest to the electrical engineer, and especially to the young electrical engineer—"the world is all before him, where to choose;" and, in my belief, a moderate proportion of those who are aspiring to make their mark as electrical engineers would choose wisely in making a very special study of that portion of the field within which lies the application of electricity to chemical manufactures.

The field is a wide one, and so far only a small corner of it has been cultivated, but that portion is already yielding rich harvests. There are now three or four flourishing electro-chemical industries of capital importance—the electrolytic refining of copper, the electrolytic extraction of aluminium, the electrolytic recovery of gold, and the electrolytic production of chlorine and of soda. Besides these, there are *other* successful chemical manufactures which rest on an electrical basis. Their importance is great even now, and is increasing. They afford opportunities for the advantageous exercise of special knowledge and skill on the part of the electrical engineer, who may be called upon to design suitable apparatus for carrying out known processes, or to invent new or improved means of effecting some unattainable but desirable end.

Considering the importance of this branch of electrical engineering, it seems to me—and I hope you may take the same view—that the time custom places at my disposal to-night will not be ill spent in a general review of *the rise and progress of electro-chemical industries.*

Early Work in Electro-Chemistry.

Two years hence there should be celebrated, in the city of Como, the centenary of Volta's great discovery, to which we owe the origin of electro-chemistry. Electrical phenomena had been diligently studied long before his time. But if we except the action of the electric spark, utilised by Cavendish to induce the combination of gases having an affinity for each other, no marked electro-chemical effect had been observed up to Volta's time. There was in fact no knowledge of phenomena due to the sustained operation of an *electric current*, as distinct from those due to *intermittent discharges.*

Closely following upon the announcement of the discovery of the voltaic pile, its analytical power was made known through the electrolysis of water by Carlisle and Nicholson. But it was Davy who first fully realised and demonstrated the transcendent power of the voltaic current to effect chemical decomposition. Davy made for ever memorable the year 1806, by the electrolytic extraction of potassium from potash. Distinctly prophetic as this was of other far-reaching kindred discoveries, I suppose that not even the imaginative mind of Davy ever entertained the idea that out of this embryo would grow any of these great manufacturing processes that are to-day shaking the foundations of some of the oldest and most important of our chemical industries.

Davy, fortunate in almost everything, was supremely fortunate in his *assistant, Faraday*. Never, surely, in the history of experimental science did the mantle of genius fall on worthier shoulders than when Faraday became the successor of Davy, and the inheritor of his methods and of his work. Great, immensely great, as is the debt owed by electrolytic chemistry to Davy, the debt is doubly great to Faraday. To Faraday we owe the discovery of the law of electrolytic conduction, without which knowledge industrial progress in the field of electro-chemistry would have been impossible; and, above all, it is to Faraday that we owe the first principles of the dynamo—principles applied to practical electrolytic work much earlier than is commonly supposed.

Even as early as 1842 there were at work in Birmingham, for the electrolytic deposition of silver and gold, power-driven electric current generators, based on the dynamo-magneto-electric principle discovered by Faraday. One of these machines I saw not long ago, still doing duty at Messrs. Elkington's factory.

During the 30 years following Faraday's discovery of magneto-electric currents, and its primitive application to electro-plating, I cannot recall in this connection any of those striking events which make a moment memorable, but the tools were being fashioned wherewith the way was to be cleared and the work of progress carried on.

Towards the end of that quiescent period, Wilde was building powerful machines for the electro-deposition of copper; and those great incentives to electrical engineering enterprise and progress, the telegraph and electric lighting, were already beginning to quicken the pace along the collateral lines of scientific and industrial advancement. To speak only of electric lighting, it should be noted that in the fifties Holmes and De Meritens had designed efficient, if costly, magneto-electric apparatus for lighthouse illumination.

The principle of magnetic self-excitation in an electro-magnetic generator was made known in 1867, and four years later the first really practical continuous-current machine was constructed by Gramme.

The two succeeding decades saw the evolution of the modern dynamo; and at the end of this period the critical point was reached when there was demonstrated, with sufficient clearness to captivate the commercial mind, the fact that for *lighting*, for *transmission of power*, and for effecting several important chemical operations, *electricity*, as produced through the dynamo, by the steam engine or by water power, was a thing of *utility*, and could be turned in all these ways to commercial advantage.

These great uses of electricity have been for several years established on the secure basis of commercial success. This result has been reached through the co-operation of many minds, and especially by the union of the *skill* of the *mechanical engineer* with the *specialised knowledge* of the *electrician* and the *chemist.*

Copper Refining.

At the outset, 60 years ago, the only electrolytic industry then in existence was comprised in that small and closely related group, electro-plating, electro-gilding, and electrotyping. Since then, and comparatively in recent years, the principle of electrotyping has been applied to copper refining. This has developed to such an extent, that now one-third of all the refined copper required in the world is produced electrolytically. In 1896 the production was 137,000 tons. The product of one works alone—the Anaconda Works—was over 30,000 tons. One great advantage of electrolytic copper refining over the old method is the saving of the gold and silver from the unrefined copper. But there is a further advantage, and one that electrical engineers especially appreciate, viz., the *higher conductivity* of electrolytic copper.

The process of electrolytic copper refining is, as you know simply electrotyping on a grand scale. An impure copper anode is dissolved, and pure copper is deposited upon a cathode in an electrolytic bath of acid sulphate of copper solution.

In this connection, I may mention experiments I made to ascertain how far it is possible to go in the direction of increase of current density without detriment to the physical properties of the metal deposited.

I found that under proper conditions it was possible to obtain tough copper with a current-density ranging from 1 ampere to 1,000 amperes per square foot of cathode surface. The conditions necessary to be observed were, to adapt the strength of the solution to the strength of the current, using, of course, the strongest solution with the largest current; and, when the current-density was high, to take suitable means to obtain extremely rapid circulation of the electrolyte. I found that regularity and smoothness of deposit were almost entirely dependent on the absence of solid particles held in suspension in the electrolyte, and that excrescences could be entirely avoided by taking care that the electrolyte was free from solid floating particles. I found also that an exceedingly rapid flow of the electrolyte over the cathode surface tended to the suppression of a crystalline condition of the deposit. This effect was most strikingly shown when the electrolyte was projected against the cathode surface with considerable force from a submerged jet. In the *Philosophical Magazine*, 1881, Vol. xii., p. 300, Tribe published an exceedingly interesting series of observations on the distribution of the lines of conduction in a liquid undergoing electrolysis; these showed me the causes of the wasteful growths round the edges of electrotypes. By applying remedies suggested by Tribe's results, I was able almost wholly to prevent this waste, to obtain nearly complete uniformity in the thickness of deposits, and entirely to prevent excrescent marginal growths. The general principle followed was the restriction of the sectional area of the electrolytic bath to, as nearly as possible, that of the plate intersecting it, so as to prevent curvature of the lines of flow.

In considering this branch of the subject, the question occurs whether it is economically possible to take advantage of the greater purity and higher conductivity of electrolytic copper that has not undergone fusion after electro-deposition. The common practice is to fuse electrolytic copper and cast it into ingots, and then proceed to roll and draw the ingots into the various sizes of bars and wire required in electrical work. This treatment results in a slight loss of conductivity. Some years ago I worked out a process in which a copper wire stretched in an electrolytic bath was, whilst receiving a deposit of copper, continually subjected to the action of wire draw-plates. This resulted in unlimited extension of the wire without increase of its thickness: all the deposit went to increase the length; and this might go on to an indefinite extent. The original wire formed a core, which, as the process proceeded, dwindled towards nothing. There are on the table some pieces of wire made in this way, in the different stages of its growth. I ascertained the possibility of producing wire in this manner; but even with a rapid rate of deposit, such as I was able to use, I found the apparatus would be excessively costly, relatively to the output; and, being allowed, by the kindness of Messrs. Bolton, to witness the method of wire-drawing employed at their works, I was so impressed by the rapidity and simplicity of their process as to feel that, looking at the matter from a non-scientific point of view, unless there was something much more to be gained than 1 or 2 per cent. extra conductivity, the play was not worth the candle. I do not know whether, by the method proposed by Mr. Elmore of cutting a spiral from an electrolytically deposited cylinder, a sufficient degree of economy of production can be obtained; but, so far, the ordinary process has not been interfered with by direct electrolytic methods of producing wire. Nevertheless, the greater purity and slightly higher conductivity of electrolytic copper that has not been subjected to the fusion treatment common in commercial practice, give to those attempts to produce wire from electrolytic copper that has not undergone fusion, at least a scientific interest and value.

A characteristic feature of electrolytic *copper refining* is that the *anode* is formed of the *same kind of metal* as that *deposited*, and *dissolves* to keep up the supply of metal in the electrolyte. There is an equal and opposite action going on at the cathode and anode. But there is another class of electrolytic operations of perhaps even greater interest to the electrical engineer, and certainly of great economic importance, namely, that class in which the *ore*, and not the already reduced *metal*, furnishes the metallic supply to the electrolyte. This opens a very large subject, since there is included in it not only the extraction of copper, nickel, zinc, gold, aluminium, and sodium, but also the great question of the electrolytic production of caustic soda and chlorine, and other substances hitherto produced by purely chemical operations.

There have been many attempts to utilise the fact that copper matte or sulphide can be *cast* in the form of *plates* or *slabs*, and that such plates have a sufficient degree of conductivity to allow of their being used as anodes in an electrolytic bath. These attempts have not always been successful, but there is an interesting exception in the case of the copper-nickel mattes worked by the Canadian Copper Company, who refine copper and nickel electrolytically, and use the matte as anodes. The mattes contain about 40 per cent. each of copper and nickel, and 14 per cent. of sulphur, together with small quantities of silver, gold, and platinum. The power used in the production of 1 lb. of nickel is nearly 1 electrical horse-power-hour.

NEW PATENTS AND ABSTRACTS OF PUBLISHED SPECIFICATIONS.

NEW PATENTS.—1898.

[*Compiled expressly for this journal by* W. P. Thompson & Co., *Electrical Patent Agents*, 322, *High Holborn, London, W.C., to whom all inquiries should be addressed.*]

632. "Improvements connected with electric lamps and switches." W. M. Walters. Dated January 10th.

665. "Improvements in electric switches." J. L. Hinds and H. H. B. Crouse. Dated January 10th. (*Complete.*)

678. "Method of diminishing the affinity of electrolytically produced chlorine." C. A. Jensen. (A. Linding-Larsen, Norway.) Dated January 10th.

698. "Improvements in or relating to the electric illumination of railway trains." B. de Szwantowski. Dated January 10th.

729. "Electric rotary cutters." F. Gardner and D. J. Smith. Dated January 11th. (*Complete.*)

735. "Improvements in switches for use in electric light installations." H. Taffs and J. Hill. Dated January 11th.

756. "An improved electrical apparatus for railway signalling during fogs." R. W. Gay. Dated January 11th.

783. "Improvements in portable electric alarms and bell sets." J. Davidson. Dated January 11th.

809. "Improvements in automatic calling devices for telephone exchanges." W. P. Thompson. (The Strowger Automatic Telephone Exchange, United States.) Dated January 11th.

812. "Improvements in or relating to dynamo-electric machinery." P. R. Jackson & Co., Ltd., and J. S. Lewis. Dated January 11th.

814. "Improvements in the means for controlling the lighting and extinguishing of electrically illuminated signs and other advertising and show tablets." J. T. Gent. Dated January 11th.

817. "Improvements in electric railway conduit systems." R. F. Thompson and E. J. Sullivan. Dated January 11th. (*Complete.*)

831. "A system of conducting electricity for propelling, heating, lighting, and telephoning from railway vehicles." H. W. Libbey. Dated January 11th.

834. "Improvements in single-phase induction motors." L. B. Atkinson. Dated January 11th.

835. "Improvements in single-phase and multiphase alternate current motors." L. B. Atkinson. Dated January 11th.

848. "An improved galvanic battery." J. von der Poppenburg. Dated January 11th.

885. "Apparatus for electro-plating articles in bulk and in large quantities." G. Langbein. Dated January 12th. (*Complete.*)

913. "An improved electropathic sock for boots and shoes." A. F. McGaw and W. A. Woodford. Dated January 12th.

932. "Improvements in the manufacture or production of electrodes for secondary batteries. C. Pollak. Dated January 12th.

933. "Improvements in electrolytical condensers and electric current directing devices." C. Pollak. Dated January 12th.

935. "Improvements in, or connected with, pole-pieces of dynamo-electric machines." C. W. Dawson. Dated January 12th.

953. "An improved telephone line switch." G. Lay. Dated January 13th.

1,002. "Improvements in electric measuring instruments." A. A. Voysey and R. L. Wilson. Dated January 13th.

1,011. "Improvements in electric incandescent lamp sockets or holders." R. J. Bott. Dated January 13th.

1,017. "Improved method of, and apparatus for, signalling or advertising by electricity." A. Ginisty. Dated January 13th. (*Complete.*)

1,021. "Improvements in the manufacture of filaments for incandescence electric lamps." C. H. Stearn. Dated January 13th.

1,046. "An improved method and electro-magnetic cut-out for automatically disconnecting charged conductors in the event of breakage or short circuit, applicable to overhead systems of electric traction and the like." R. C. Quin. Dated January 14th.

1,073. "Improvements relating to graphic or writing telegraphy." R. Hurley. Dated January 14th.

1,114. "Improvements in telephone exchanges." J. O. O'Brien, of the firm of W. P. Thompson & Co. (G. Ritter, Germany.) Dated January 14th.

1,127. "Improvements in electrical safety devices." H. M. Salmony. Dated January 14th.

1,140. "Improvements in electro-magnets for electric traction." H. H. Leigh. [The Gesellschaft zur Verwerthung elektrischer and magnetischer Stromkaft (System Schiemann and Kleinschmidt) Ad., Wilde & Co., Germany.] Dated January 14th.

1,145. "Improvements in electric cables." G. C. Allingham and W. Fennell. Dated January 15th.

1,194. "Improvements in secondary batteries." G. Philippart. Dated January 15th. (*Complete.*)

1,213. "Improved apparatus for the electro-decomposition of water." Sir C. S. Forbes, Bart. Dated January 15th.

1,216. "Method and means or apparatus for facilitating the erection of overhead telephone, telegraph, and like wires or conductors." J. Hallet. Dated January 15th.

ABSTRACTS OF PUBLISHED SPECIFICATIONS.

Copies of any of these Specifications may be obtained of Messrs. W. P. Thompson & Co., 322, High Holborn, W.C., *price, post free,* 9d. (*in stamps*).]

1896.

19,469. "A means of surrounding electric or other lights with a vessel or lining of glass or other material containing liquids." E. J. Macready. Dated September 3rd, 1896. Globes, lenses:—Oil, gas, electric or other lights are placed in or near glass, porcelain or other vessels containing coloured or other liquids between the walls. The vessels may be ornamented and divided to contain several liquids.

19,501. "Improvements in electric light conduits." B. M. Drake and J. M. Gorham. Dated September 3rd, 1896. Tubes or conduits are joined together or to junction boxes by means of slightly coned ferrules. The ends of the tubes may be slightly tapered and may be cemented in.

19,650 "Improvements in insulators." T. Blenkinsop and J. W. Brown. Dated September 5th, 1896. Insulators for electric incandescent lamps are formed of glass and have a metal core passing through the screw and shoulder. A cutting edge under the shoulder seals the screw opening. The head of the insulator is formed with a nut, a wire groove and a shed.

SUBSCRIPTION RATES.—In *Great Britain*, Post Free per Year, 19s. 6d. To all other countries, per Year, £1 4s.

BINDING.—Subscribers' numbers bound, including case, for 4s. each volume.

CASES.—Cloth Cases for Binding can be had, price 2s. 6d. each.

READING CASES, to hold from One to Twenty-six Numbers until the Volume is complete for Binding, can now be had from the Publishers, Price 6s. or Free by Post (in Great Britain), 6s. 6d.

FOREIGN AGENTS.—*New York:* D. VAN NOSTRAND, 23, Murray Street. *Paris:* VEUVE J. BOYVEAU, 22, Rue de la Banque. *Berlin:* ASHER & Co., 5, Unter den Linden.

Cheques and Postal Orders (on Chief Office, London) to be made payable to Mr. H. ALABASTER, 4 Ludgate Hill E.C.

THE BURNING QUESTION.

No branch of business connected directly or remotely with the electrical industry is at present showing more activity than that concerned with the much-debated dust destructor. We were witnesses of and participators in an enterprising event on the 27th inst., when some 200 engineers, surveyors, chairman of committees, and other influential gentlemen, from all parts of England, inspected the dust destructor at Leyton. The guests came by invitation of the Urban District Council, but the syndicate that built the destructor was very much in evidence. "The voice was the voice of Jacob, but the hands were the hands of Esau."

That veteran sanitarian and eminent engineer, Captain Sir Douglas Galton, R.E., was the "lion" of the occasion, just as Lord Kelvin was the "lion" of a similar function held at Shoreditch some time ago. Each guest was provided with a neat little brochure having a picture of the works as a frontispiece. The brochure first describes briefly the problem and afterwards the solution. In our opinion the problem is insufficiently set forth, and the statement of the solution gives as a sole result the total amount of refuse and sewage sludge burnt in tons during the year 1897, and as a deduction therefrom the amount burnt per cell per 24 hours.

The destructor is next described and the two 96-horse-power water-tube boilers in connection therewith. It is stated that the temperature of the combustion chamber frequently reaches 2,500° Fahr. Favourable opinions of Sir Douglas Fox, C.E., and Mr. Francis Fox, C.E., are next given, and also an extract from the report of Mr. William Dawson, C.E., engineer and surveyor of the Urban District Council. Finally, the Council state that their reason for putting these facts before their visitors is their desire to share with other municipal authorities any ideas that may prove of assistance and value to them. The facts referred to should also prove of considerable assistance and value to the enterprising makers of the destructor, the Beaman & Deas Syndicate; and we may say that we welcome this attitude of a local authority in assisting a firm that has, in their opinion, served them well, by joining with them in such a function as that of last Thursday. Too often local authorities discourage any attempts at legitimate advertising undertaken by the firms whom they employ.

But when we come to criticism from an engineering point of view, we must confess that we think far more is embodied in the problem than the mere destruction of the refuse and sludge, and as regards its solution, it will be necessary fo us to know what is the cost per ton burnt—for labour, repairs, interest on first cost, and so forth, before we can arrive at a fair judgment. As we have stated before in these columns, we regard the problem as not admitting of a single solution, but it requires first that the apparatus shall work without nuisance, either from smoke or dust; second, that the refuse, or refuse and sludge, shall be completely burnt; third, that the temperatures shall be high enough to ensure complete combustion with maximum steam raising capacity; and, finally, and most emphatically, that the cost of labour per ton burnt should be as low as possible consistent with fair wages and fair hours of labour to the workmen employed. The brochure is unfortunately quite silent on every one of these points, except as to the temperatures, and deals only with the amount burnt per cell, which we regard as quite a minor consideration. The amount burnt per cell is high, but that is not a special feature of any destructor, as it is simply a question of the strength of blast and the number of men employed. Given a strong enough blast, and a sufficient number of men, a very large amount of refuse can be burnt per square foot of grate per hour, and an instance is on record in which in a destructor of another type, 26·75 tons were burnt in a cell in 24 hours. This was at Leeds, and the figures were published by the Medical Officer of Health, Dr. Spottiswoode Cameron. As regards steam raising, we noticed that the boilers were blowing off at 105 lbs. on the occasion of the "Public Inspection," and 95 I.H.P. was stated to be about the amount of the power daily used. This is approximately about what might be expected, and it may be considered a good result in view of the wet nature of 30 per cent. of the material being burnt. It is, no doubt, somewhat of a feat to burn sewage sludge successfully, while at the same time raising a fair amount of steam; but it is a curious fact that sludge is not difficult to deal with in a destructor, as is proved by the fact that Mr. Jones, C.E., the well-known surveyor of Ealing, has successfully burnt it in a natural-draught low-temperature destructor for many years past, in proportions just about the same as those adopted at Leyton, namely, one-third sludge, and two-thirds refuse. This seems to have escaped the notice of the directors of the Beaman and Deas Syndicate, who state that no destructor has hitherto been capable of destroying wet sewage sludge, but a perusal of the letter from the Ealing surveyor, which will be found in our "Correspondence" columns, may serve to point a moral, if it does not adorn the tale of the "remarkable new departure" at Leyton. The temperature stated in the brochure as attained in the furnace, namely, 2,500° Fahr., is a somewhat fanciful figure. We venture to surmise that no such temperature has ever been accurately measured; but probably somebody has judged it "by eye." It might as well be estimated by "rule of thumb." So far as we know, such a temperature as that has not hitherto been reached in burning ordinary house refuse, much less in burning such wet stuff as sewage sludge. The electric light plant is employed in lighting the works only, and the current is generated by a 3-kilowatt machine. There is, therefore, no fitting opportunity for a further outburst of correspondence in our columns, similar to that which has recently raged around the Shoreditch plant.

While at Leyton we were also presented with the report referred to in the brochure of Sir Douglas and Mr. Francis Fox. This interesting report supplies, to some extent, the information omitted from the brochure. The results given are based upon a 12 hours' trial and must be judged accordingly. The sludge was found to average nearly 65 per cent. of water. We may note that the term "pressed sludge" is used, but it is very questionable whether the expression can be legitimately applied to sludge which contains so large a percentage of water, and, further, it may be pointed out here that this water requires only to be warmed to a temperature of 212° in order to send it up the chimney, leaving a comparatively small amount of dry material to be dealt with.

In spite of this the residuum from the refuse and sewage sludge, taken together, is 29·4 per cent., which we regard as somewhat high, considering the nature of one-third of the material. The weight of water evaporated per lb. of material is given as 0·426 lb., or 0·507 lb., from and at 212°. The pressure of air in the ashpits, namely, 2 inches of water, is excessive, as might be expected from the amount burned per cell. The temperature of the combustion chamber is given as 1,562° F., which we may point out is a very different figure from the 2,500° F. of the brochure. The very hot appearance of the combustion chambers seemed to us to be partly due to the red hot particles of dust blown up from the surface of the fire by the excessively strong draught.

Sir Douglas Fox's Report also omits all mention of the fact which we consider of most importance, namely, the cost of labour per ton burnt, in relation to the wages paid, and the number of hours worked by the men. Until these figures are forthcoming, it is impossible to judge between the Leyton plant and destructors of other types.

The City Electric Lighting Service.

The high rates per unit charged by the City of London Electric Lighting Company are naturally, and, we think, very properly, creating a great deal of dissatisfaction among consumers. The City authorities have over and over again expressed regret that the company's powers run over so long a period, and they have brought weight to bear upon the company to secure a reduction in the charges. The company, however, not having inclined its ear unto these words of advice, may have to grapple with the bug-bear of competition, if the propositions now receiving attention by the Court of Common Council come to anything. Whether the Court has or has not the necessary power to compete with the company to which it has granted certain clearly defined concessions, is a matter which will arise in connection with the Court's deliberations directly; but we think the City company would be acting under good advice if it lowered its rates as other companies have done which touch the borders of its own area, without inviting competition in any shape or form. That in the long run a competitive supply would be beneficial to the general City public, and detrimental to the interests of the present company, there is hardly room for doubt. From all accounts, the City Company is doing remarkably well and can easily afford to consider the interests of its consumers in this way. It will perhaps be said that if the rates are reduced there will be a much greater demand for light beyond the company's present or immediately prospective capacity, but that, we venture to think is a matter that can be easily arranged. Of all things the company should avoid a short-sighted policy.

Electric Motors on Hire.

Mr. Alfred H. Gibbings, the Bradford Corporation electrical engineer, who is showing so much enterprise in popularising electricity supply in his city, has sent us a copy of a circular which his Corporation has issued, giving the conditions, charges, and so forth, as to the hire of electric motors. This is mainly for the benefit of small power users in the district to whom a heavy outlay on motors and equipment would be prohibitive. The motors on hire range from ½ to 6 H.P., the rates exclusive of fixing, being from 10s. to 30s. per annum. These low rates bring the advantages of electric power within easy reach of the power consumer, and we should think some good work will thus be done at Bradford and the other towns where the hire of motors is proposed. The gas companies find their best customers among those who consume gas for driving gas engines, and for heating and cooking, and there is every reason to believe, now that the use of small electric motors is becoming more general, that electrical engineers will do much by this means to improve the electricity works' day load.

HIGH ELECTROMOTIVE FORCE.*

By Prof. JOHN TROWBRIDGE.

I have lately perfected a large plant for the study of the discharges of electricity through gases which I believe is more extended, and on a larger scale, than any at present in existence; and I have obtained some results with it, especially in the subject of high electromotive force, which throw light upon many mooted points. The source of electricity which produces the electrical discharges is obtained from 10,000 storage cells. From these cells I obtain very approximately 20,000 volts, and by means of a peculiar

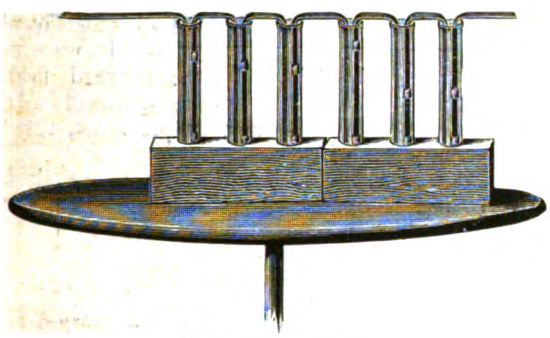

Fig. 1.—The Cells.

apparatus called Planté's rheostatic machine, I am enabled to obtain over 1,000,000 volts—which enables me to experiment with powerful discharges in air, more than 4 feet in length.

By the employment of storage cells in the subject of the discharges of electricity through gases, one can form a fair estimate of the amount of energy that is employed to

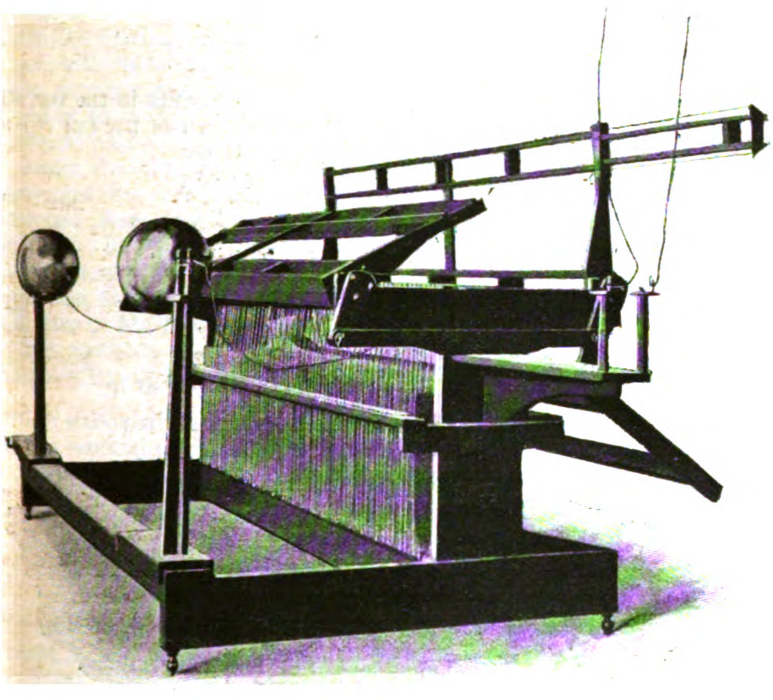

Fig. 2.—Plante Rheostatic Machine.

produce the desired effects—for instance, the X rays; while with the use of electrical machines or induction coils and transformers it is extremely difficult, if not impossible, to form an accurate estimate. Fig. 1 is an illustration of the type of cells of which the battery consists. Each cell is composed of a test tube $5\frac{1}{2}$ inches long and $\frac{3}{4}$ of an inch internal diameter containing two strips of lead which are separated from each other by rubber bands and are immersed in dilute sulphuric acid. The surfaces of the lead strips are roughened by a mechanical device, and the cells are charged in multiple circuit by means of a dynamo machine. When the cells are properly formed, each one gives two volts and has an internal resistance of one-quarter of an ohm. The problem of insulating these cells was a serious one; but it was practically solved by mounting the cells in sets of threes, in holes bored in a block of wood which had been carefully boiled in paraffin. The mechanician of the laboratory, Mr. George Thompson, devised a simple switchboard which enables me to throw the cells into multiple or into series—to use the entire 10,000, or suitable portions of this number. The battery gives 8 amperes of current with 20,000 volts, and this amount of energy is amply sufficient to kill a man. By accident an operator received the shock from only 1,000 of the cells and was badly shocked and burned. It is prudent therefore in experimenting with this battery to use rubber gloves, even in throwing the switches, and it is recommended to employ only one hand covered with a rubber glove and to keep the other hand in a pocket.

I had at first intended to use this large battery in the study of electrical discharges through Crookes tubes, but I speedily found that X rays could not be excited by a difference of potential represented by 20,000 volts. I found that at least 100,000 volts were necessary to produce them strongly, and I, therefore, resolved to construct a Planté rheostatic machine. This machine is simply an apparatus by means of which Leyden jars are first charged in parallel and are then discharged in series or by cascade. That is, all the inside coatings of the jars are connected to the negative terminal of the 10,000 cells, and all the outside coatings are connected to the positive terminal of the cells. When the cells are charged, the inside of one Leyden jar is connected to the outside of the next, and so on. In this way a very high electromotive force can be obtained. I use 60 Leyden jars in the form of plates of glass 15 × 18 inches coated on both sides with tinfoil. Starting with 20,000 volts, I can exalt this to 1,200,000 volts. The accompanying illustration (fig. 2) shows the Planté machine. The mechanician of the laboratory has introduced a notable improvement in the apparatus of Planté. Instead of a revolving commutator such as was used by the latter, Mr. Thompson employed lever arms, by means of which the jars were first charged in parallel and then discharged in series. It was found that the apparatus designed by Planté could not be used for higher voltages than one or two thousand without serious error and loss. By means of this apparatus I can study electrical discharges at least 4 feet in length—of great body—which are produced by an electromotive force of 1,200,000 volts. This apparatus possesses the great advantage that it enables one to obtain a fairly exact measure of such high voltage. When we reflect that the trolley car employs only 500 volts, and in the system of transmission of power from Niagara Falls it is proposed to use only 10,000 volts, it is evident that the effects produced by voltages of over a million must be of great scientific interest.

The study of such high electromotive forces immediately showed that previous estimates of the electromotive force necessary to produce a spark of a certain length were highly erroneous. For instance, Heydeweiler, a German investigator, believes that Prof. Elihu Thomson's statement, that a spark of 5 feet in length which he produced required a voltage of 500,000, is very wide of the mark, and Heydeweiler maintains that 100,000 would be nearer the truth. I find that even Prof. Thomson's estimate must be more than doubled. Experiments with my apparatus show conclusively that the length of the electric spark between points

* *Scientific American.*

separated by more than 1 inch varies directly with the electromotive force. A spark 48 to 50 inches in length requires an electromotive force of 1,200,000 volts, and a discharge of lightning one mile long would therefore require the enormous number of over 100,000,000 volts. In reflecting upon the development of such enormous energy in the air, we can understand why telephone bells ring during a thunderstorm; why subsidiary sparks occur in networks of wires; and why telegraphic messages are interrupted. The world beneath the thunderstorm throbs and pulsates with the oscillatory discharges of lightning.

One of the most interesting results of my study of powerful disruptive discharges is the discovery that such discharges will pass through glass tubes which are exhausted to such a high degree that they are said to contain a vacuum; for the 8-inch spark of a Ruhmkorff coil prefers to jump around the tube to passing through the extremely rarefied space in the interior of the tube. Such tubes, however, are brilliantly lighted by a difference of potential of 1,000,000 volts and readily show the X rays, and exhibit the skeleton of the hand in a fluoroscope. The so-called brush discharge from the positive terminal of the Planté machine extends visibly to a distance of over a foot. If the hand is exposed to this brush, it produces the well known X ray burn, such as various investigators have received in taking photographs of the skeletons of their hands, or in testing the condition of Crookes tubes by exposing their hands before a fluoroscope. The skin of the hand becomes irritable and turns a bright red colour, especially after exposure to cold winds.

This result interested me greatly; for it proved that the so-called X ray burn could be produced by the brush discharge of very high electromotive force. The extent of the influence of this powerful brush discharge is very great. For instance, photographic plates in a plate-holder carefully insulated from the ground and covered with a plate of glass half an inch in thickness show the inductive action of the brush discharge from the positive terminal, which is distant at least a foot. These inductive effects are manifested by star-shaped figures on a photographic plate. They are surrounded by dark clouds. When the burn on the back of one's hand produced by such brush discharges is examined by a microscope, similar centres of disturbance (in this case points of inflammation) are seen. Although the Leyden jars of my machine are carefully insulated on supports of vulcanite which are mounted on dry wood, which in turn is supported on rubber, I can obtain a discharge of more than 2 feet in length when I bring a point connected to the steam pipes to the neighbourhood of one terminal of the machine. The other terminal of the machine is carefully insulated. This experiment shows conclusively that it is of no use to insulate lightning rods. My experiments thus far show that no vacuum which I can produce can resist the discharges which are caused by 1,000,000 volts. It now becomes an interesting question whether there exists mechanical or chemical means by which a so-called vacuum can be produced which will resist such discharges.

SOME NOTES ON SINGLE-PHASE MOTORS.

By A. C. EBORALL.

(*Continued from page 68.*)

The following conclusions may be arrived at, considering the oscillating field of a single-phaser to be of the nature indicated above:—

1. At starting, two equal and opposite torques are exerted on the rotor by two equal fields rotating with equal velocities in opposite directions. Hence there can be no initial torque.

2. As the rotor slowly increases from zero up to a speed near synchronism, the backward rotating field becomes weaker and weaker, and since the backward and forward fields have together to produce a definite back E M.F. in the stator windings, the forward rotating field must increase in strength, and consequently the resultant torque on the rotor rapidly increase.

3. When the rotor is nearly synchronous, the backward rotating field is reduced to a very small amount. Hence it may be said that on starting, the resultant field is purely oscillating, but when running, the effect of the rotor currents is to produce a nearly pure rotating field. In the rotor bars a complicated current exists, it being the sum of two currents of different frequency, they being of approximately equal strength. The one is due to the very small backward rotating field, and is of high frequency, the other to the main forward rotating field, and is of low frequency. The $C^2 R$ losses in the rotor must, therefore, be nearly double of those in a multiphase rotary field motor. In other words, nearly half the $C^2 R$ losses in the rotor of a single-phaser are due to the backward torque × speed of rotor, this amount of power being simply wasted in heating the rotor conductors. The iron losses will also be greater than in a multiphase motor, owing to the effect of the backward high frequency field.

4. There is a limit of speed before synchronism at which the torque on the rotor again falls to zero. If we consider the rotor running synchronously, the forward field can evidently produce no torque, whereas the backward field gives rise to a negative torque. The zero torque must, therefore, be before synchronism is reached.

5. The effect of leakage or self-induction is entirely detrimental. It has two effects: (1) it diminishes the main torque due to the forward rotating field, and (2) it likewise causes the backward field to be larger in proportion to the forward field. This can be seen from the following:—Let ϕ be the lag of the current behind E.M.F. in one rotor bar. Then the diagram of E.M.F. for this bar is that shown in

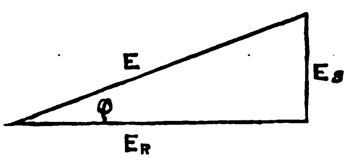

Fig. 5.—Diagram of Rotor E.M.F.

fig. 5, E being the resultant of E_s, the E.M F. of self-induction, and of E_r, the E.M.F. for the ohmic resistance. From this

$$\sin \phi = \frac{E_s}{E}.$$

Now $E_s = 2 \pi n L C$, where C is the current in the bar, and n the slip. Also the E.M.F. induced in one bar (E) $= \pi n N$ where N is the strength of field. Hence

$$2 \pi n L C = E \sin \phi$$

$$\text{or } C = \frac{\pi n N \sin \phi}{2 \pi n L} = \frac{N \sin \phi}{2 L}.$$

$$\text{But } \sin \phi = \frac{2 \pi n L}{\sqrt{R^2 + 4 \pi^2 n^2 L^2}} \qquad \text{(Fig. 6).}$$

$$\text{Therefore } C = \frac{N \pi n}{\sqrt{R^2 + 4 \pi^2 n^2 L^2}}.$$

From this it is clear that when the self-induction is already the main term in the impedance factor, an increase of L produces a proportionate decrease of C. Where, however, the

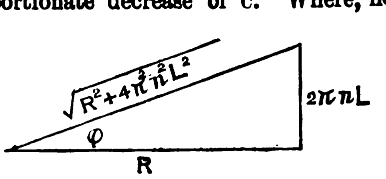

Fig. 6.—Diagram of Rotor Impedances.

self-induction term is but small, the decrease in C is small for a given change in L. The result of this is that the backward field produces a smaller value of backward high frequency rotor current, and consequently where the two currents are equal to one another, the backward field is larger in proportion to the forward field for an increase in L.*

* It is a common error to suppose that self-induction in the motor is absolutely necessary in a successful single-phase motor. It has arisen by not considering that the backward rotating field tends to disappear for the small slips that are met with in practice. The best induction motor of any kind is the one with the least leakage, that is, self-induction.

The construction of single-phase induction motors can now be gone into. Briefly, it may be said that they are constructed in exactly the same way as multiphasers, but with slight modifications, caused by the fact that they are not self-starting, and that the considerations mentioned above have to be borne in mind. The methods used by different designers, in order to get over the starting difficulty, will be described later; generally speaking, these methods take the form of splitting up the single-phase current at starting into two currents differing less than 90° in phase, one of these currents being sent round the working winding of the motor, the other going round a starting winding, the coils of which are wound in between those of the main winding. Hence an irregular two-phase rotating field is produced, which causes the rotor to run up to a speed somewhat short of synchronism, and this being attained, the starting winding is cut out, the working winding put direct on the supply mains, and the load transferred from the loose pulley or other device to the motor pulley. The starting torque depends on the efficiency of the phase-splitter, on the current taken, and on the design of the motor, and is, generally speaking, not very great.

Before considering the construction of these motors in detail, it will be as well to briefly enumerate the general points that must be followed in regard to their electrical and magnetic design.

Firstly, a very essential point is, that both stator and rotor should be quite smooth all round—large polar projections on either must be avoided. If this is not attended to, there is (especially at starting) a tendency for the stator and rotor fields to cog into one another, and as a consequence the effective starting of the motor is rendered impossible.

Secondly, the air-gap must be only just large enough to permit the rotor to run freely without danger of touching. As the no load current and power factor at all loads depend mainly on the size of the air-gap, it is clear that it must be as small as possible. Further, the larger the air-gap, the greater the leakage, and hence the motor will not start so well, and will have a greater slip when running, and diminished power factor.

Thirdly, if the induced rotor currents are not confined to proper paths, so that they may be always properly contributing to the driving forces, there will be false rotor currents which will waste power by heating, and which may even under certain circumstances exert a torque in the opposite direction to that of the forward stator field, and help the backward field.

Lastly, the arrangement of the stator winding and iron parts must be such that the leakage field is a minimum, otherwise there may be eddy currents in the motor frame, and even in the stator conductors themselves, causing loss of energy; furthermore, if there is much leakage from any cause, the bad effects before mentioned will be present to a greater or less extent.

The methods adopted in practice to satisfy these conditions will now be considered.

(*To be continued.*)

SMALL LIGHTING PLANTS.

An article headed "Small Lighting Plants," by Mr. Fred. C. Reeve, in the *Electrical World*, deals with three important questions, namely:—

1. Can the lighting companies materially lower the present rates if brought into competition with the "isolated plant?"

2. Are very small plants, varying in size from 25 to 300 lights, practical?

3. Under what conditions can they be made a success financially?

The basis of his calculations are taken on the average prices charged in America for the four most popular illuminants, and are as follows:—

(*a*) Ordinary gas light, costing ·875 cents per 16-C.P. hour.

(*b*) Incandescent gas light, costing ·65 cents per 16-C.P. hour.

(*c*) Incandescent electric light, costing ·90 cents per 16-C.P. hour.

(*d*) Enclosed arc light, costing 6 cents per 1,500-C.P. hour.

In cases where the demand for current is spread over a large number of hours, such as large factories and workshops, where the items of interest and depreciation would therefore be spread over a large number of units, it is shown by a table of costs of operating plants that electricity can be generated privately at a less cost than the average price generally charged.

Persons will gladly pay for the convenience afforded by the central station supply in their houses, but in the store, factory, or workshop where economy has to be practised, the matter is treated differently, and these considerations account for the large number of isolated plants in America, and no doubt also at home in England.

The rapid spread of electricity within the last few years, and the publicity given to the details of cost in generation, management, &c., have set probable large consumers thinking, and their education has in many cases led to the loss of good customers, for knowing that dynamos can be relied upon to work practically without attention, and with little fear of breakdown, the additional responsibility of an extra machine in a large works spreads itself over the whole just as the items of interest and depreciation spread themselves over a larger number of units generated, and logically speaking, the larger the works the less the additional responsibility is felt.

The isolated plant of to-day is quite different from that of a few years ago. Before the introduction of central station supply, we were indebted for a good deal of our early knowledge to isolated plants. Just as doctors must learn their profession and patients must be practised upon, so had the electrical engineer to learn his profession, and the isolated plant owner was often the patient sufferer, the martyr to science. The disappointments and failures of the days referred to were often due to the scant knowledge then possessed by the engineer, and these failures have led to such improvements, that it is difficult to see where further improvements can take place.

The lessons taught were not long in being acted upon, and central stations began to make their appearance at different places some ten years ago, and have gone on increasing year by year, each succeeding year bringing more and more. The primary lesson learned was, that electricity generated in sufficiently large quantities could be generated cheaply and made a commercial commodity. The owners of large works, shops, stores, &c., have also learned this, and following in the footsteps of their former tormentors, are putting down their own plants, some of which rival in capacity many central stations.

Although isolated plants are not adapted for domestic light, except for country residences where current cannot otherwise be obtained, it is obvious from the silent evidence of the increase of isolated plant in business premises, that when a sufficient number of lamps are installed, and when they burn for a considerable time each day, the current can be very cheaply generated.

It points to the fact that sooner or later electricity will have to be supplied at a very much cheaper rate than at present, or the steady commercial lighting will be operated by the isolated plant, and the only customers retained will be the domestic and intermittent commercial work.

The systems of charging for current must be considerably modified to enable the business man to cheaply light his factory if current is to be bought, and he must pay a higher rate for current used for domestic purposes.

COMPARATIVE COST OF STEAM AND ELECTRIC POWER.

I.

Electrical power transmission being as yet in the aggressive stage of development, and called upon to show cause why it should be adopted, it is natural, that from time to time, should appear comparisons of costs with steam power. One of these appear in the *Electrical Engineer* (New York), by Mr. Irving A. Taylor. So far as regards steam power costs in America and here, the probability is that comparisons made in one country will stand good for the other. Mr. Taylor attributes the small attention given to power economy to the idea that power is only thought to be a small item in total costs of manufacturing, and also to the fact that power distributing is a special subject not understood much by manufacturers. There is nothing easier than power distribution, and anyone can get out a plan for doing it, but it is all done by guess work, and the result is often an expensive tangle of belts entirely preventing the use of overhead travellers, as well as being enormous power absorbers. It is not simply the sheer cost of power that is to be counted, often enough it is the incidentals, and this is specially the case where small steam engines are employed.

So much depends on arrangement, and the author cites the case of a shop remodelled to give a four-fold output, which produced as much as seventeen-fold with ease. In this case, arrangement combined with electrical transmission and compressed air for certain duties has been the cause of improvement. Now, air power is costly, but it is extremely useful in the right place, and though giving only 15 per cent. efficiency, being used cold, it saves in labour and increases output. The question is asked, what is the best way to lay out a power plant? The answer is, that where large amounts of machinery are to be driven, certain power centres may be found to which, while power is being used, power may be supplied at a fairly constant rate, and with a high load factor. Such centres may supply simply one machine, or a group of machines, a whole floor or section of a shop, but no large power must be sent far along a line of shafting or a number of belts. There is a tendency to medium sizes of motors, 3 to 15 H.P. They ought to be fairly well loaded, and their efficiency must not be obscured by complicated belt systems. When the load on a machine or a group is nearly constant, the group or unit is to be as directly connected as possible to the motor. Machines absorbing a small but variable power require grouping in considerable numbers on one motor, so as to obtain an even average. Where possible, variable and steady demands should be separated. Thus we want to run a 5-horse blower all day, and a couple of machines consuming from 0 to 10 H.P., and averaging about 2 H.P. The costly part of this load will be the blower. If we use a 15-H.P. motor, the costly load will be run usually on a half loaded motor, through belts and shafts, and will cost double what it would if it were run with a 5-H.P. motor on the blower shaft direct. The group would thus require two motors. But if the maximum load of 10 H.P. on the other machines had never fallen below an average of 7 to 8 H.P., possibly one motor would best have served the group. The author is very severe on a crossed belt. With its two rubbing sides exerting a backward pull of $7\frac{1}{2}$ lbs. at 2,200 feet per minute, the cost of this 1 H.P. of friction will be £20 to £60 a year, a rather expensive price for a crossed belt!! There is no excuse for a crossed main belt, and only necessity should permit any crossed belt to be run. The author saved 50 per cent. of power by uncrossing a main belt. It took half an hour to arrange this. Belts are often the best transmitters for short spans. For spans of 100 feet, a wire rope will be satisfactory where loads do not vary suddenly; but in America wire rope transmission has not been a success—it demands too many conditions; is too curbing. The same applies to compressed air. It is used in Paris, with reheating to 300° or 400°—an essential to economy for large air power. But who wants a fire to make up? People who buy power want it ready cooked, not raw, like compressed air. Electricity has the maximum of convenience and the minimum of waste over any distance, and is bound to win on the score of convenience, if for no other reason. The trouble with electricity is, so far, with those who sell rather than with those who buy. There is so much hesitation in replying to an intended user's questions. It looks as though there were doubts as to success, and so on, and this is not encouraging to users. In Mr. Taylor's further discussion of the question he gives figures to show the advantages of electricity which we propose to reproduce.

AN ELECTRICAL HYPOTHESIS FOR THE SOLAR AND PLANETARY SYSTEMS, AND SOME OF THEIR ASSOCIATED PHENOMENA.

By DELTA.

(*Continued from page* 74.)

II.

Since the first article was published in the Electrical Review, the solar eclipse of 1898 has been carefully observed, and under favourable conditions, and according to cable information the general shape of the solar corona was generally like that seen in the eclipses of 1867, 1888 and 1896, so that it may be assumed that there is little variation, if any, in

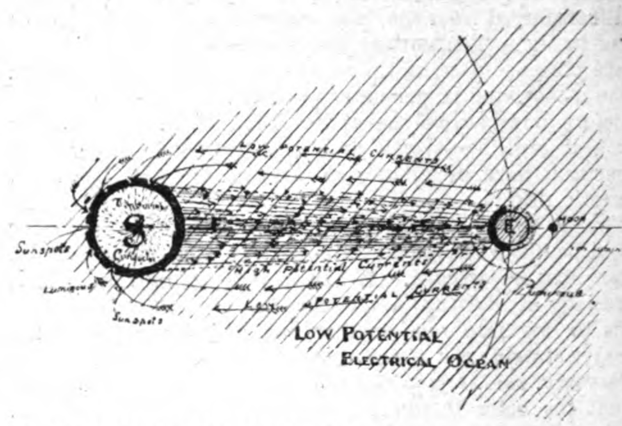

Fig. 1.—Graphic Diagram showing the Cycle of the Conservation of Energy forming the Basis of the Solar Electrical Hypothesis.

the sun's great electrical potential. The varying luminous intensity of the solar triple and concentric envelopes is merely due to the varying degrees of resistance offered to the outward passage of the high intensity electrical energy. The photosphere is probably composed of gas of such high tenuity, as to offer no resistance whatsoever.

The diagram, fig. 1, is intended to graphically explain the author's electrical hypothesis. Fig. 2 gives a rough idea of

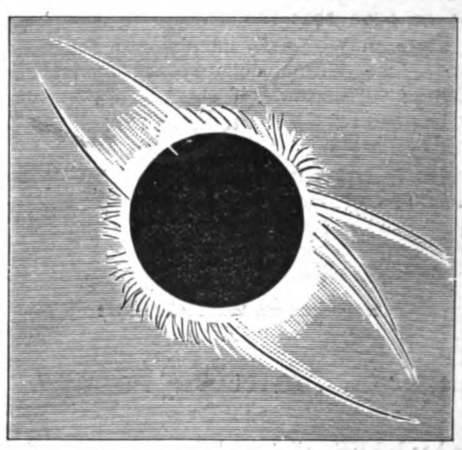

Fig. 2.—Total Solar Eclipse, July 29th, 1878, showing Electrical Streamers.

the appearance of the solar corona. Before proceeding to extend the application of the electrical hypothesis to explain stellar and other phenomena, it may now be an advantage to examine its value, as an explanation of common atmospheric effects.

Cloud Effects.

Aqueous vapour, in the form of clouds (by the well-known attractive influence that water has for electricity), may be said to constitute suspended electrical conductors, that become electrically charged to saturation.* The discharge of these

* An electrically charged cloud induces electricity of an opposite kind to its own.

cloud forms of electrical conductors may be induced by the earth itself, or by a highly electrified wind current, and also by the influence of solar electrical currents that produce the ultra-violet rays.

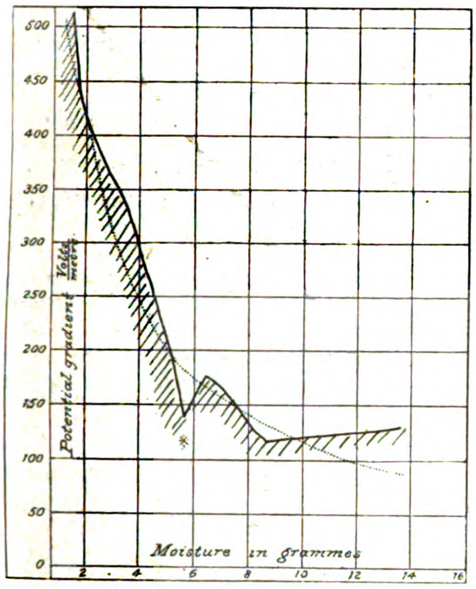
The discharge of the clouds will be induced by contact with any strongly electrical energy absorbing surface.

The strange phenomenon of the water spout, the aqueous column uniting the clouds and the sea, is an example of the powerful and irresistible attractive influence of masses of water, that culminates in the rapid discharge of the clouds' electrical accumulation.*

There are always stronger indications of electrical energy on hills than in valleys.

The Influence of Aqueous Vapour on the Electrical Condition of the Atmosphere.

The influence of the proportion of aqueous vapour in the atmosphere in its effect on the degree of resistance offered to the flow of electric energy is well known.



——— Actual curve. .... Estimated curve.

Taken from Elster & Geitel, *Fitz K. Akad der Wiss, Wien.*

Fig. 3.

The discharge of a rain cloud rapidly clears the atmosphere from an excess of electrical energy. The influence of a highly aqueous vapour condition in altering the electrical potential of the atmosphere is shown by diagram, fig. 3. This diagram 3 is constructed from tabulated results of observations made at Hofner Sonnblick at an elevation of 10,168 feet above sea level, and also at the low level station of Kohn Saiguon. It will be noticed, on referring to the graphic diagram, fig. 3, that the curve of electrical potential runs in a line inversely to that of aqueous vapour pressure.

A casual test made at Massachusetts, by means of a kite connected by wire with a quadrant electrometer, was raised and maintained at some elevation above the summit of Blue Hill, at such a position as to intercept an approaching thunderstorm.

At 7.40 a.m. this thunderstorm, which for some 20 minutes had been approaching from the west, was near enough to cause an incessant stream-like flow of sparks from the kite-string.

If a ground wire was held within a fraction of an inch from the kite string, a spark discharge followed.

After the rainfall, no sparks or any electrical indication could be drawn from the kite-wire.

Cloud disruptive discharges occur when the electrical tension in the atmosphere between the clouds and the surface of the earth exceeds a certain critical value not yet determined.

It would appear that as the voltage increases with the height of elevation from the earth's surface that clouds at various heights will have distinctive electrical characteristics; therefore we should expect that cloudland will be essentially of a stratified character.*

The variation of electrical potential from the inception to the termination of a thunder storm is a striking proof of the masterly factor that electrical energy occupies in terrestrial processes, and is itself evidence of no inconsiderable value in supporting the author's new hypothesis.

Thunder, Hail, and Snow Storms.

Diagram fig. 4 shows the striking variations of electrical potential during thunder storms, at both an upper and a lower placed station.

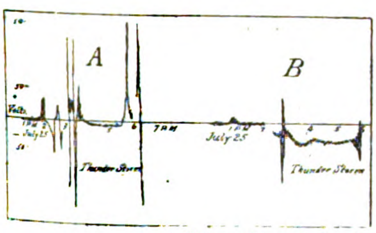
The diagram 5 shows the normal variation of potential characteristic for fine weather. It will be observed that the electrical intensity shows a decided drop from morning until evening.

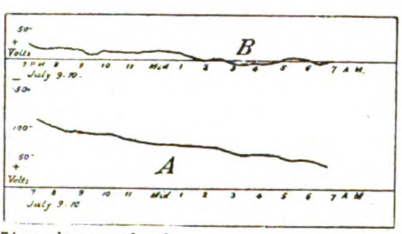
The violent changes of electrical potential of our atmosphere are not only associated with thunder storms. During hail and snow storms we have acute changes of potential. The diagram fig. 6, for which we are indebted to Mr. McAdie, is a very striking exhibition of the great potential fluctuations that exist during a snow storm.

The observations at Sonnblick indicated that cloudless days were associated with an apparently constant and equable fall of potential, maximum (July) between 7 and 9 a.m., followed by a regular reduction of potential to a minimum at the evening.

Observations in a cloud that discharged a small quantity of rain showed the electrical potential to gradually drop to zero value, where it remained for some time.

It has been noticed, as a rule, that in storm clouds the atmospheric electricity usually changes its sign after a lightning discharge, the same change occurs with storms occurring on a plain.





A 194 m. above sea level, and B 74 m. above sea level.

Electrical Potential of the Air Photographically Registered at Two Stations.

Fig. 4. Fig. 5.

The Formation of Hail and Snow Particles.

It is well known that the flow of static electricity between pointed terminals, and through an atmosphere charged with particles of suspended matter, in a condition free from moisture, has a very curious effect. Some of the particles become immediately electrolysed and polarised, and they form nuclei centres of magnetic attraction and aggregation, the small particles rapidly coalesce to form larger ones.

One might attribute the formation of hail, and, in a manner, perhaps, of snow or other forms of frozen vapour, to this action of electrical coalescence.

In hail storms the highly electrical condition of the atmosphere is particularly noticeable. The electrical intensity potential was noticed by the observers at Sonnblick to increase and decrease with the fall of hail.

Diagram, fig. 6, shows the violent electric changes that accompany a snow storm.

Probably the electrical coalescence forming hail takes place at the altitude coincident with that of the Cirrus cloud, at some 5½ miles distance from the earth's surface.

---

* Peletier states that water spouts are accompanied with striking electrical manifestations.

* Hildelrandsson showed that the upper currents move along somewhat parallel to the lower currents, up to a certain height.

According to the law enumerated by Leys:—

Upper clouds have a distinct centrifugal tendency over areas of low pressure, and a centripetal one over those of high.

The Variation of Electrical Potential in Winter and Summer.

The average atmospheric electrical potential is higher in winter than it is in summer—there is less moisture as such in the air, and the absorption by the earth will, it is thought, be slower in winter than in summer.

The moisture in summer months constitutes an excellent

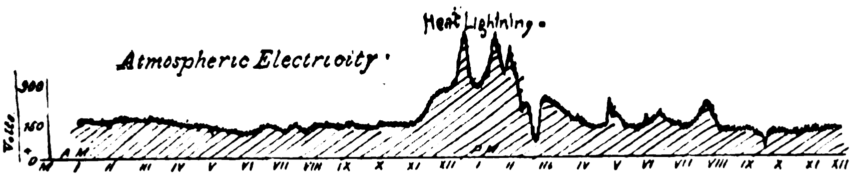


Fig. 6.

conductor for the flow of the electricity to the earth's surface.

Dryness of air, on the other hand, offers a greater resistance to the flow of electrical energy, and hence the tendency to the creation of a highly electrified atmosphere, a prelude to the atmospheric electrical phenomena we know as the magnetic storms.

The Increase of the Electrical Intensity Potential with Increase of Altitude.

If the author's electrical theory is correct, it would mean that the solar electrical intensity potential would be highest at its entrance into the earth's atmospheric envelope, and that by the dispersion of part of its energy in generating heat and light it would become less and less as it approached the earth's surface; or, inversely expressed, *the electrical potential would increase in proportion to the distance from the earth.*

That this is so is shown by diagram fig. 7. The curve shows the rise of electrical potential with height above the surface of the earth.

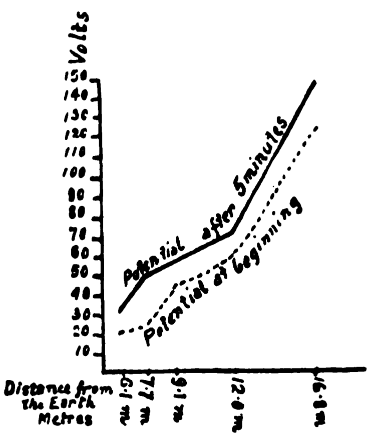

Fig. 7.

Exner's experiments with the water droppers, and made at comparative low levels, showed that whilst the voltage at a height of 17 metres was 100, it increased at a height of 40 metres to 280. He deduces from this that there is a rise of 6—8 volts per metre of elevation.

The Limit of Extent of the Sun's Atmospheric Envelope.

Before enlarging further on this important fact of rise of potential, which in itself clearly shows that the earth cannot be considered to be the primary source of electrical energy, because if it did the electrical intensity would be greatest at the surface, let us attempt to define the limit of the earth's atmospheric envelope. By calculating on the basis of the pressure exerted by the atmosphere upon the earth, equivalent to 30 inches of mercury, the atmosphere only extends some five miles; but this calculation is obviously erroneous, from its neglect to allow for the highly tenuous character of the fringe of the earth's atmosphere.

Meteors having been noticed to evolve gas at a distance of 120 miles from the earth, it is clear that even at this distance extreme atmospheric attenuity cannot have been reached.

That the resistance to the flow of the high tension solar electric currents does not commence to be of sufficient intensity as to produce any luminous or day-light effect until it reaches a distance of 45 miles from the earth is shown y the duration of twilight.*

The all of the electrical potential will vary with the density of the atmosphere, so that Exner's factor of 8 volts increase per metre of distance can only be taken as in any way reliable within a short distance from the earth.

If we take half this factor, or 8, to represent the rise of potential per metre of elevation, we should then have a voltage value, at only five miles distance from the earth, of

$$\frac{†1,609 \times 5 \times 8}{2} = \text{to } 32,180 \text{ volts.}$$

The Zone of Electrical Potential.

If the electrical energy flowing from the sun at high tension and frequency enters the atmosphere, and is absorbed by the atmosphere and the earth, the latter must constitute the zero of potential. The discharge of low intensity electrical energy from the earth into the low potential electrical ocean will not generally illuminate the atmosphere, although there are evidences of such discharges from prominences that have produced luminous effects. Such an example is suggested in the phenomenon of Saint Elmo's fire.‡

Wind and other Currents Electrically Initiated.

Wind currents—particularly those carrying with them suspended particles of hail or snow, are highly electrical, and there is little doubt but that high potential electrical discharges play as important a *rôle* in the production of wind currents as does the more generally accepted explanation of the cause, the effect of heat.

The discharge of a high tension current from one to another, or from a point on to the atmosphere, *sets up a decided flow of air.*

If it is accepted that high tension solar currents flow at their maximum at the equator, then this line will coincide with the initiation of powerful and continuous trade winds. Any chart showing the direction of the prevailing winds will demonstrate that the trade winds are initiated at the equatorial line.

That the discharge of electrical energy into the ocean, will indirectly influence the ocean currents, is probable. The maximum oceanic absorption of electrical solar energy at the equator, may constitute this locality as a locale of initial motion of oceanic currents.§

The wind currents flow from the land to the sea at night, and from the sea to the land at the day time.

The general theory for this change of direction being the alternate influence of the heat of the earth and that of the sea.

The inflow to the earth of the high tension electrical currents in the day, and the outflow of this energy at night, may by repulsive influence on the air have some part in the play of the natural forces, producing the wind currents.

The Relation of Barometric Influence on the Electrical Intensity Potential.

The degree of atmospheric resistance to the flow of elec-

* Slightly luminous clouds have occasionally been seen at night that were calculated to be at a distance of more than 45 miles; it is suggested that their interception of strong solar light intensity electrical currents has produced the strangely luminous effects, silver clouds in an atmosphere of the darkest night.

† Mils reduced to metres.

‡ Buchan records 15 cases of Saint Elmo's fire emitted at night time from the summit of Ben Nevis, between the years 1883 and 1888.

§ The oceanic currents appear to flow from the north, from the south poles, towards the equator, establishing cycles of direction, north and south of the equator.

trical energy being a function of the atmospheric density, it will, therefore, be obvious that a change in the barometric pressure will set up varying resistances, and varying electrical repulsive effects that will cause wind currents. Another cause would be the generation of heat as a *pari passu* effect of the increased resistance to electrical flow, and this heat would tend to expand the air, a common means of producing wind circulation.

It has long been known that some connection exists between the height of the barometric column and the direction of wind currents.

For instance, 10 years' consecutive observations have shown that the least mean barometric height corresponds to the great south winds, and the greatest mean height corresponds to the great north winds. The change of barometer will necessarily mean a change of atmospheric electrical potential, and either an increased or decreased, and corresponding degree of repulsive action, on air.

It has been explained that the dispersion of electric energy of high intensity from a pointed conductor, sets up wind currents by electrical repulsion, it is not, therefore, an improbable suggestion to put this cause as the master one amongst other, and purely physical causes, that set up the flow of air currents. It has been suggested that highly-electrified wind currents may, independently of temperature influence the discharge of highly-aqueous clouds of accumulated electric energy.

Temperature of the Upper Atmospheric Strata.

Let us assume that the temperature of the atmosphere depends upon the resistance offered to, and on the proportion to the electrical energy passing through the atmosphere. The resistance is a function of the atmospheric density, and as the density of the atmosphere decreases, as its distance from the surface of the earth increases, this would necessarily mean that in proportion as the distance from the earth increased, the temperature would decrease; in other words, the temperature would in some measure be inversely proportionate to the distance from the earth's surface.

Aerostatic observers have discovered at the equator, that for each elevation of 187 metres there is a drop in temperature equal to 1° C.

Taking the temperature at the equator to equal 25° C., then at a distance of five miles the temperature will equal

$$25 - \left(\frac{5 \times 1{,}609}{187}\right) = 18^\circ \text{ below zero.}$$

Now, from evidence that has already been adduced relating to the Cirrus clouds and to cometary bodies, it is quite certain that outside the five miles of atmospheric environment the temperature is very many degrees below freezing point. We have nearer evidence in the fact of the mountains being capped with everlasting snow.

If the ordinary theory were correct, these prominences would be the first to meet the assumed rays of light and heat from the sun, and the summit of the mountain would be hotter than the valleys around its base. A somewhat similar objection applies to the ordinary theory of transmission of light from the sun.*

The Zodiacal Light.

The electrical hypothesis provides one speculative explanation for this phenomenon. It is suggested that the apex of the zodiacal light is the outer fringe of the earth's atmosphere, having such a density that by resistance to the flow of electric energy, it is capable of being made luminous. As the atmosphere projects miles beyond the earth's surface when an observer is on the surface of the earth removed some limited distance from the area upon which solar electric energy is acting, he should be able to see the reflection of the earth's luminous atmosphere in the form, say, of part of the frustrum of a sphere.*

* To demonstrate this difficulty one has only to formulate the following argument:—

Axiom.—The intensity of light is inversely as the square of the distance from its source.

Hypothesis.—If the ordinary theory were correct, the maximum intensity of sunlight (which is considered to be four times that of the electric light) would and sequentially be equal at the sun to the determinate quantity, x, given by the equation

$$z \times (93{,}000{,}000)^2 = x,$$

where z equals the photometric and thermal value of the sunlight at the surface of the earth, and this z quantity may be calculated thus: the temperature of an ordinary arc and actinic light has been variously estimated, but if we take it to equal 2,500° C., then the intensity of the light at the sun will be equivalent to a temperature that is beyond the regions of even the wildest fancy, and this figure alone appears to be fatal to existing theories.

The Supreme Importance of the Subject of the Electrical Condition of the Atmosphere—a Suggestion.

Before proceeding to the application, necessarily highly speculative, of the electrical hypothesis to the planetary, stellar, and their associated phenomena, the author wishes to emphasise the urgent, if not supreme importance, of the subject of the electrical condition of the atmosphere. This subject transcends all others, not only in its relation to vegetable organic life, but also to that of human life. The stimulating effect of electrical energy on vegetable life is well known, and this subject alone deserves national recognition.

The author is satisfied that it will be found correct to say that nearly all diseases, and more especially those having a nervous origin,† are in some measure connected with specific electrical atmospheric conditions, and there is little doubt but that the conditions that best secure immunity from any epidemic or other disease, will be found to be coincident with *pari passu* electrical characteristics, but especially with the atmospheric electrical potential.

We must have day by day records of the variation of electrical potential and other electrical changes, along with the barometrical indications from all our meteorological stations. The meteorological stations should be increased at least to double the present number, and be supported by the State.

With this electrical data, we should be able, if not to prevent, at least to counteract the influence of an electrical potential found to be dangerous to satisfactory health conditions of either animal or vegetable existence.

A human sufferer could be removed to positions when the electrical conditions were found to be hygienically beneficial.

By means of the proposed stations the prevalence of electrical changes, magnetic storms, and other electrical phenomena, would soon supply abundance of data of incalculable value to the well-being of the people.

The correlation of the electrical characteristics with hygienic, astronomical, and atmospheric, and other effects could be more exactly determined, and there would then be no necessity to incur blame and displeasure in attempting to formulate speculative theories, however well justified they may be, by correlative and coincident evidence.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

At the last meeting of the Institution of Electrical Engineers, held on Thursday, January 27th, at the Institution of Civil Engineers, Major-General Webber read a paper entitled "Notes on the Electro-Chemical Treatment of Ores Containing the Precious Metals." General Webber prefaced the presentation of the actual paper by explaining that the subject was such a broad one, while his remarks were confined to one or two particular departments thereof, he did not feel justified in describing what he had to say as more than "Notes." The paper, like many others laid before the Institution, is evidently intended to awaken and stimulate thought on particular matters, and is timely as following up the subject matter of the presidential address so recently delivered. We allude to it at length in another column.

On conclusion of the paper, the President called upon M.

* Prof. Bigelow considers the zodiacal light merely as an amassment (in the plane of the sun's equator, and at a place of zero potential) of particles electrically propelled from the sun.

† Every living thing on earth may be rightly considered to be a producer of electrical energy, and each one is more or less highly, if unconsciously, susceptible to the varying electrical conditions of the atmosphere. We have an example of this in the prevalence of neuralgic and similar attacks at certain phases, as yet undefined, of the electrical and atmospheric potential.

Pelatan to open the discussion. This gentleman modestly disclaimed a thorough acquaintance with the English tongue, and stated that he thought the paper gave full particulars of the process in which he was interested, but expressed his willingness to give any further details that might be desired. Later in the evening M. Pelatan had the opportunity of dealing with some of the criticisms, and ably put forward his views in excellent and clear English.

To Dr. Teed fell the part of leader of the attack, and this position he filled with evident relish, and at considerable length. He opened by stating that the paper wanted pulling apart and reconstructing, particularly by setting those processes which are intended for the electrical removal of metals from solvents on one side, and on the other, such as are intended for the making of solvents by electrical treatment. Thus the Siemens & Halske process was one for removing gold from a solvent, while the Pelatan-Clerici had in view the making of a solvent, and dissolving out the gold by this solvent. Molloy, whose name was mentioned in the paper, only attempted to remove gold from a solution, by making a sodium amalgam.

Coming to the Pelatan-Clerici process, Dr. Teed expressed his wish to have explained the meaning of the statement in the paper that certain mixing was done in the treatment tank itself, part of the gold being alleged to be extracted in the vat, and part after the liquor had left the vat. He considered the chemistry of the process involved, while nothing seemed to show that one sort of ore was differentiated from another. Ferritic ore, for example, could not be treated electrolytically, but must be dead roasted first. Then as to cost, the question was, what did it cost to agitate per ton of ore, and how much did the electric current cost per ton? Following this, Dr. Teed cited several processes in which potassium cyanide alone was used to extract the gold from an auriferous ore, the quantity of cyanide employed per ton being less than that mentioned as necessary in the electrolytic process. Warming up to the attack, the Doctor continued that the facts put forward honestly in the paper formed a condemnation of Petalan-Clerici process, and asked, "Could any opponent say anything more virulent? Ridiculous is not a strong enough word for it."

After a few remarks from another speaker—Mr. Herroun, of King's College, on the chemistry of the last-mentioned process—Mr. Sulman, whose name, jointly with that of Dr. Teed, was referred to in the paper in connection with the Sulman-Teed process, rose to wish every success to the process so strongly condemned by his partner, to name certain processes of historical interest which were omitted in the first part of the paper, and finally to pile up a list of theoretical and practical objections to the Pelatan process, particularly questioning the advantages of having to agitate, the improvement in yield due to this process, and the cost of the necessary plant, energy, and solvent. He concluded by stating that it might be that unwittingly an injustice might have been done to the process, but economy is the touchstone of any method of extraction, and by cyanide alone 90 per cent. of the gold can be got from an ore.

Several speakers dealt generally with the subject of the paper; one expressed himself as looking with extreme sympathy upon the attempts to utilise the old Hungarian Mill with the use of electricity to keep the mercury alive.

M. Pelatan then rose to give explanations on some of the detail points referred to by different speakers. He stated that in the mixing vat a quantity of pulp collected, and that the gold was actually got partly in one way and partly in another; the first treatment, lasting two hours, being performed without electrical assistance, a certain quantity of gold was taken up in the mercury.

With regard to the former used in agitation, it was necessary to compare things and processes that were comparable, and the particular use made of agitation in his case, was very different to what was attempted by other inventors. Thus some processes require the cyanide, vat and stuff to be agitated, but he only desired to agitate the pulp undergoing treatment in the vat, and he had found by experience that only half a horse-power was required to stir up five tons of crushed ore.

The consumption of cyanide depended upon the condition of the ore treated, the tailings on the Rand were in a washed condition, the slimes having been taken away already. In any case the figure of 2 lbs. of cyanide per ton, was a very great maximum, and in every-day practice he had not found it necessary to use such a large quantity.

At this point the discussion was adjourned, and the meeting broke up, a general topic of conversation, as the members trooped from the hall, being the extraction of gold, not necessarily, however, from ores, or by electro-chemical means.

LEGAL.

IMPROVED ELECTRIC GLOW LAMP COMPANY *v.* EDISON & SWAN UNITED ELECTRIC LIGHT COMPANY, LIMITED.

This case, which was briefly noticed on page 122 of last week's ELECTRICAL REVIEW, was heard before Mr. Justice Mathew, in the Queen's Bench Division, on Thursday 27th ult.

Counsel for the plaintiffs, Mr. Bousfield, Q.C., M.P., Mr. Wallace, Q.C., and Mr. A. J. Walter. For the defendants, Mr. Fletcher Moulton, Q.C., and Mr. J. C. Graham.

Mr. BOUSFIELD, in opening the case, said the plaintiffs were a company incorporated in March, 1896, their name indicating the nature of the business they were proposing to undertake. The defendants were an old-established and well-known company, having a very high reputation in the electric lighting world, the demand for lamps of their make being very large. That being the state of the case, the plaintiffs being a new company bringing out a new lamp, negotiated with the defendants for its manufacture. The lamp differed from the ordinary type. The ordinary lamp was pear-shaped. The plaintiffs' lamp, on the contrary, endeavoured to get the lower surface as flat as possible, and the upper surface of such a curve that the two together, when part of the glass was silvered, gave the most favourable results as regarded illumination. It was cheaper, gave greater lighting power, and consumed less than the ordinary lamp. The negotiations took place between Mr. Fanta, the managing director of the plaintiff company, and Mr. Jacob, who at that time was the general manager of the defendant company. The basis of all the discussions was, that the defendants should work with the plaintiffs in bringing out the new lamp. The motion was, that the defendants should be the sole manufacturers of the lamp, should supply it to the plaintiffs, and share with the plaintiffs in the profits of the trade resulting from the introduction of the article, which both should push. On the basis of that arrangement, an order was given for the manufacture of 100,000 of these lamps, which was in writing, and was the only contract upon which they were suing in this action. The defendants began to manufacture under this contract, and to make deliveries under it. The date of the contract was the letters of November 3rd and 9th, 1896, and the rest of the arrangement was reduced to writing on November 26th. They could never get the rest of the arrangement confirmed in writing, and it never was. In the meantime, while this arrangement was going on, unknown to plaintiffs, the defendants experimented and introduced a lamp which was nothing more nor less than an absolute copy of the plaintiffs' lamp, the only difference being that instead of the reflecting part of the top being silvered, it was made of opal glass. The defendants had taken out a patent for their lamp on January 10th, 1897, but the plaintiffs did not know this until a later stage. They knew, however, from the delays that were taking place that there must be something wrong. On March 5th, 1897, they learned what was the matter when an advertisement appeared in the ELECTRICAL REVIEW announcing that the defendants had introduced a new orb into the incandescent lamp world. This lamp was called "The Queen of Lamps." It was described as giving a perfect diffusion of light, and as being unquestionably the lamp of the Diamond Jubilee. An action was brought by the plaintiffs against the defendants for infringement, but with that his Lordship was not now concerned. The defendants thus avowedly entered into competition and rivalry with the plaintiffs with a lamp which, as far as bulb was concerned, and everything else except the substitution of opal for silver, was identical with plaintiffs. During the months of April and May, 1897, the total deliveries were under 4,000; that was to say, that during the eight weeks preceding the issue of the writ on May 20th, there was only two weeks' supply delivered. Up to the present time there was still a small number of lamps unfinished under this order. The defendants had alleged that the delays were due to the plaintiffs not giving them instructions as to certain details, such as "capping," but that was not really the case. The capping was a simple question, and could be done at the rate of 800 a day. As a matter of fact the plaintiffs had agreed to pay for the lamps as completed lamps at the stage before they were capped, the defendants to keep a quantity in stock and then "cap" them. It was quite impossible in this trade for the plaintiffs to put the lamps upon the market until they had accumulated a stock, unless they had somebody behind them like the defendants, who had a large output of such articles. If the plaintiffs' arrangement had been carried out when they had got 10,000 or 20,000 accumulated, they could have put the lamps on the market, but without someone behind them like the defendants, who could manufacture at a rapid rate, it would had been necessary for them to have accumulated 30,000 or 40,000 lamps. There were three different voltages and four different candle-powers so that altogether there were to be twelve varieties of lamps from the one shape, namely, the conical. The first specification was for 66,000 lamps, of which 46,000 were to be of the conical and 20,000 of the round type. The plaintiffs had a large Continental trade where foreign lamps were considered as good as English made, but these particular lamps were required for the

English market, and it was essential that they should be of English manufacture. In consequence of the failure of the defendants to fulfil their part of the contract they had to carry out certain English contracts by supplying foreign-made lamps, whilst other orders they had to reject.

Mr. Justice MATHEW suggested that the question of liability should first be considered.

Mr. MOULTON said it would perhaps assist the Court if he stated the defendants' view of the case. It was that no contract had ever been entered into. Unquestionably an arrangement was made that the defendants should supply the plaintiffs with lamps to the extent of 2,000 a week. The letter of November 9th left matters still to be arranged verbally, but the next letter showed it was very much a matter of doubt whether any strict contract was ever entered into. There was a good deal of trouble in making the lamps originally, and hence there was some delay; but the defendants were always supplying the lamps. The plaintiffs, he contended, did not suffer any business damage whatever, and as to the allegation that the defendants put a rival lamp into competition with that of the plaintiffs, there was no foundation for such a statement. The defendants did not receive the specification from the plaintiffs when they ought to have done, and again they were entitled to a reasonable delay for capping. There never was a time when the plaintiffs could not have as many completed lamps as they required.

Evidence was then called for the plaintiffs.

Mr. FANTA, managing director of the plaintiff company, examined by Mr. BOUSFIELD, said the sole object for which the company was formed was to manufacture and sell this improved glow lamp. In 1896 he had several interviews with Mr. Jacob on behalf of the defendant company, and negotiations as to the manufacture by the Edison-Swan for the plaintiff company. Mr. Jacob said he knew if they were to manufacture the lamps the two companies would have to work hand in hand. Altogether there were three or four interviews before the letters of November 3rd and 9th. Ultimately, pending the acceptance of terms, on order was given and accepted for 100,000 lamps to be manufactured by the defendant company. Witness gave evidence as to the nature of the contract, which was disclosed in the letters. He said that the total number of lamps, both of round and conical shape, invoiced by the defendants in accordance with the contract up to April 7th, was 17,279. Of these, 8,904 were conical, and 8,375 round. Between March 31st, the date of the last delivery, and May 20th, the date of the issue of the writ, the total number of lamps delivered was 4,600. Assuming that at that date there should have been delivered 30,000 conical lamps in accordance with the contract, only 8,904 had actually been delivered. Of the 8 or 10 candle-power lamps, 18,000 should have been delivered, but up to the date of the issue of the writ only 597 had been supplied. This failure of delivery had prevented witness's company from placing the lamp on the market from the very beginning. They wanted to put on the market an English-made lamp, which was suitable for the English market, being much more durable than the foreign-made article. The price they were to be paid for a certain lamp to the defendants' company was 1s. 1d. per lamp, but they could get a similar article on the Continent for 6d. It was not so good as the English make, nor was it so durable. As the defendant company did not supply the lamps according to the contract, the plaintiffs could not put the articles on the market because they had no stock. That meant if they had secured orders their small stock would have soon been exhausted, and they could not have continued the supply, which would have been detrimental to the company. Had the defendant company conducted the supply according to their contract the plaintiffs could have put them on the market as they had originally contemplated.

Cross-examined by Mr. GRAHAM: The policy of his board was to have English-made lamps, which were to be manufactured by Edison and Swan, who had offered to do the work. The plaintiffs did not go to another manufacturer when there was delay on the part of the defendants, because the latter were continually promising there should be an improvement in this respect. It was not the appearance of the defendant company's advertisement in the ELECTRICAL REVIEW as to the "Queen of Lamps" that first made his company feel irritation. There was no irritation then and there was not now. His company were not undecided as to the marking of the lamps until January. They were quite decided about the matter from the outset, but the defendants pointed out certain difficulties. The "Queen of Lamps" would have served their purpose when the defendants had failed to supply the other lamps, but the "Queen" would have cost them much more than they had agreed to pay the defendants for the manufacture of the lamp specified for.

Mr. Justice MATHEW expressed the opinion that the real measure of damage would be arrived at by taking the difference between the price in the "Queen of Lamps" and the price of the contract lamp, assuming that the plaintiffs had gone and purchased the former lamp and put it on the market to the extent in which there had been non-delivery.

Mr. GRAHAM submitted that what they were inquiring into was what damages had in fact been sustained, not, theoretically, what damage had been suffered.

Mr. Justice MATHEW: No, indeed, you are not. You are inquiring into what the proper measure of damages is, and I see no better method than the old-fashioned one I have indicated.

In further cross-examination, the WITNESS stated that his company had not as yet contracted with customers for the supply of English-made lamps, because they were not in a position to do so. They required a large stock to do this, and they had not that sufficient stock which would enable them to open a market in the article, and keep up the supply. He denied that his company caused any delay by the failure to give instructions as to the "capping" arrangements.

Mr. L. MANTELL, manager of the National Liberal Club, deposed that an 8 candle-power lamp of the plaintiffs' company gave exactly the same light as the ordinary 16 candle-power lamp. He spoke from experience of the lamps at the Criterion, where the Edison-Swan lamp was superseded by the plaintiffs. The lamps were of German make. It was contemplated changing the lamps at the National Liberal Club in the same way, but as the lamps of the plaintiffs were of foreign make, they were objected to. Mr. Fanta, however, had been told that when he could supply an English-made lamp the change would be carried out.

Mr. ALFRED HENRY WALTON, electrical engineer, agreed with the last witness as to the saving in illuminating power effected by the plaintiffs' lamps, which had been adopted with success at the Empire Theatre. The lamps being foreign made had a shorter life. and witness had told Mr. Fanta he should not give orders for further lamps until the plaintiffs could supply him with the English-made article.

This closed the plaintiffs' case.

Mr. MOULTON, for the defence, said that now, practically, the whole of the lamps contracted for had been delivered. That was to say, the 66,000 for which there had been a specification had been delivered, and of the 34,000 the defendants were prepared to give delivery. There had thus been a carrying out of the contract, and if damages could be recovered, it could only be on the ground of delay. What damages had been incurred here? Soon after they had entered into the contract the defendants commenced to deliver the lamps, and although they delivered slowly, still the plaintiffs, at the very time they brought the action, had in stock 16,000. Surely it could not be said that they had not then a sufficient quantity to enable them to commence the sale. The fact was, that they were not selling the English-made article, but a German lamp. The lamp manufactured for them by the defendants was not a lamp which would be sold in large bulks, and when they had 16,000 in stock they might very well have chosen to commence their sale. They had at the present time 54,000 lamps properly delivered, but notwithstanding this they had not even yet commenced the sale. Why should the defendants be made liable to pay damages to the plaintiffs when the latter had made a determination not to commence to sell until something like 60,000 lamps had been delivered? They never gave the defendants the slightest hint that they had come to this determination. As to the question of prejudice, there was nothing whatever in it. Of the "Queen" lamp, out of 4,000 no fewer than 3,700 were 16-candle-power lamps—that was to say, of the very type of which they kept over-delivering to the plaintiffs. That was, he submitted, a complete answer to the charge that the defendants were keeping back the competitor to the "Queen" lamp. He admitted that there had been delay, and the defendants were quite willing to behave reasonably to the plaintiffs on this account.

Mr. Justice MATHEW thought that the parties might give their counsel authority to settle the case on the basis of assessing what should be paid by the defendants to the plaintiffs in respect of the delay that had occurred in delivery, and he would then discuss the matter with them.

Mr. Bousfield and Mr. Moulton having got the requisite authority from their respective clients, retired to his Lordship's room to discuss the matter with him.

After a brief absence they returned into Court, when it was announced that it had been agreed that there should be judgment for the plaintiffs for £750 and costs.

SALMONY & COMPANY *v.* THE IMPROVED ELECTRIC GLOW LAMP COMPANY, LIMITED.

IN the Queen's Bench Division of the High Court of Justice on Friday, January 28th, the case of Salmony & Co. *v.* the Improved Electric Glow Lamp Company, Limited, came on for hearing before Mr. Justice Kennedy. Mr. Tindal Atkinson, Q.C., and Mr. F. Abrahams were counsel for plaintiffs, and Mr. Rufus Isaacs for the defendant company.

Mr. TINDAL ATKINSON said the action was brought to recover £287 15s. 1d., being balance due for the supply of electrical fittings and lamps. The defendants had paid £138 7s. 4d. into Court, leaving a balance due of £149 odd. There were no pleadings, and there were only two items in the plaintiffs' account, which was sent in to the defendants, in dispute. One was of £156 13s., and another an item of £67 14s. 2d. Those items related to the sale and delivery of certain holders to fix the glow lamps upon. There was a counter-claim. The defendants said that the goods were not delivered at the proper time, and that when they were delivered they were rejected by the defendants, but ultimately taken into their possession on the terms that they were to act as agents for their disposal. That plaintiffs emphatically denied. They said the goods were supplied within a reasonable time and were accepted. Although defendants demurred in the first instance, the goods were ultimately accepted, and they had used a quantity of them. The payment of £138 into Court, he understood, included payments in regard to the items he had last mentioned, and an item of £75 which defendants said was all that was due on a sale of £100 worth of goods, they having deducted 25 per cent. commission. Plaintiffs said that that was all moonshine, and that they never agreed for defendants to act as their agents in any shape or form. All the goods, in fact, had been ordered by them for themselves. Then there was a counter-claim to recover, as he understood, £700 under these circumstances. In 1895, his clients, who were electrical engineers in Charing Cross Street, had control of the agency for the sale of these silvered lamps. They were little electrical lamps which went into a fitting, and which were silvered on the top side so as to reflect and increase the amount of light. That was an agency for the United Kingdom and the colonies, and they were agents for a Mr. Schwarber, of Berlin, who he supposed was the inventor. The plaintiffs under that contract had effected some business, and among other contracts they had disposed of some of these lamps to a Mr. Brown, of Eastbourne, and Mr. McLeod, of Glasgow. The contracts with McLeod and Brown were really contracts of agency; that was to say, that these people had agreed to become the plaintiffs' agents for the disposal of the lamps, and they had also become personally liable to take from them a certain quantity of the lamps, and pay for them, and in addition act as agents in their particular districts. A person of the name of Fanta was the promoter of a particular syndicate which was purposing to take over the sale of these lamps in the United Kingdom, and also to acquire the patent rights. He could not carry out that unless he had been appointed agent, and in the latter part of April, 1895, Fanta negotiated for the transfer to the syndicate of the agency which the plaintiffs held. He was informed of the existence of the contracts with Brown and McLeod, and it was evident that it was intended by Mr. Fanta that he should have some considerable object in view to show that the persons whom he expected were to form the syndicate. The result of those negotiations was contained in an agreement, and it was under that agreement, and an assignment which followed, that the counter-claim was made. The company made an assignment of the contracts on December 16th, 1895. Counsel then went into particulars of the various contracts and their construction, and said that under them the company made various claims, one of which was, that plaintiff, was to take no less than 22,500 lamps from them, whereas he had only agreed to take 4,500. That he regarded as an attempt at imposition. One result of what took place was that Messrs. McLeod & Brown refused to be handed over to the syndicate. The parties met, and there was a long discussion and correspondence, which counsel read. It applied to the orders alleged to have been given and repudiated, and to the delay in the delivery of the various appliances which had to be manufactured in the interior of Germany, and shipped from Hamburg. He contended that all that his client's undertook to do was to have the things made and delivered as quickly as possible, and said it was a fact that 2,200 out of the 2,500 holders were received by the defendants in time to be used at the Jubilee. When plaintiffs sent in their invoices they were returned. Their books had been inspected, and there was no trace of any agency or commission accounts, nor any detecting as to goods not delivered according to contract. He suggested that there was really nothing either in the defence or counter-claim, and called Mr. Henry Max Salmony, the plaintiff; but before he gave his evidence he was recalled from the box, and a consultation took place between him and counsel on both sides with a view to arriving at a settlement. There was, however, no result, and plaintiff then gave evidence in support of his counsel's opening statement. He maintained, as had been admitted by the other side that he had fulfilled his part of the contract entered into, and that was the position he now took up. He and his firm did their best to get the goods delivered from Germany in time for the Jubilee, and many of them arrived soon enough to be so used. He had never admitted that the goods were late in delivery, or that he agreed to allow the defendants to retain them and sell them on a commission of 25 per cent. The usual condition of commission for such a transaction would have been 5 per cent.

The hearing was resumed on Monday, and judgment was given for plaintiffs on the counter-claim, and also on the claim, with costs.

CAWTE *v.* PENNY-IN-THE-SLOT ELECTRIC SYNDICATE.

THIS was a claim brought before the Taunton County Court by a Taunton electrical engineer for £14 for goods, and £25 for breach of warranty. Early last year the Electric Light Extension Syndicate made arrangements with him to do their free wiring at Taunton. After waiting a good time he found that the company, although obtaining orders there, was not carrying out the work, and when he communicated with the company he was informed that a new company would take over all responsibility and arrange with him. Mr. Cawte did certain work, and the Penny-in-the-Slot Syndicate communicated with him. For the defendants, it was claimed that the company had not taken over the Electric Light Syndicate, and had nothing to do with the plaintiff's claim. They had the option to take over, but did not do so. Mr. Bastian, managing director of the Electric Light Extension Syndicate and the Penny-in-the-Slot Syndicate, gave evidence, and said that the Extension Syndicate were prepared to admit the claim of £14 7s. for goods supplied. The claim was amended, and judgment given for the plaintiff for that amount, the question of damages falling through. Defendants' costs were refused.

SALMONY & CO. *v.* THEERMAN & CO.

IN the Westminster County Court, on Wednesday, the part-heard action by Messrs. Salmony & Co., against Messrs. Theerman & Co., electricians, of Manchester, was concluded. The claim was for £8 for a resistance, and the defendants stated that the article supplied was not of the dimensions ordered, and he was only willing to pay £3. The case had been adjourned for the attendance of a witness, Harris Rosenberg, who now gave evidence, that he was one of the plaintiffs, and after the delivery of the machine, he saw the defendant who said he was surprised at its elaborateness, and that it was delivered too late for his purpose, but he would keep it at £3. That he declined to do, and he arranged that he would take it back if he gave them large orders, but the traveller who took the order left them, and being a friend of defendant's, he cancelled all the orders. He only agreed to take it back upon future large orders being paid for, but the orders were all cancelled after the traveller left. The only orders which had been executed were small ones.

Cross-examined by Mr. WOOD: The order was to be from 45 to 50 amperes, not 45 only. Nothing was said as to price. Their catalogue was priced up to 30 amperes. The metal was all right; it was made of galvanised iron wire. If it had been made of silver wire and alloy, it would have been much smaller than this one, and lighter.

On behalf of the defendants, Mr. FREDERICK TAYLOR, a consulting electrical engineer, of 14, Victoria Street, S.W., said the machine could be made much smaller, and equally serviceable. The resistance would work, but was too large. About £3 to £3 10s. would be the price of a German silver or a platinoid one. He could not expect to get a machine like this from looking at the illustration in plaintiffs' catalogue, from which the order was given.

Cross-examined: Crompton's made resistances, but that was not their speciality. Defendant said he had since bought one of the same resistance for £3, and the weight was 2 qrs., whilst the weight of this one was 2 cwt.

For the plaintiffs, Mr. DUNCAN WATSON, A.I.E.E., said that the resistance was a reasonable one. It was a very substantial one.

His HONOUR, after a long and patient hearing, found for the plaintiffs, remarking that, it being an unusual size, the price was higher than was generally the case. He allowed £7 for it, with costs.

CORRESPONDENCE.

Refuse Destructors.

My attention was, a few weeks since, called to the discussion which has for some time occupied a considerable space in your valuable REVIEW, and I further note in your last week's issue that my name, in conjunction with Mr. Laws, of Newcastle, and Mr. Yabbacomb, of Bristol, was introduced by a writer who would like to know our opinion upon the destructor question as now before the public. I do not know, Mr. Editor, what the particular views of the gentlemen named may be with respect to making their opinions known; but I do not think I shall be far wrong when I say that, with the individual experience which we have in the working of the destructor, we neither of us care about entering into a public discussion, through the columns of the press, when the principal writers upon the subject at the present time are manufacturers or those who are interested in the sale of some particular form of furnace—every one, of course, claiming premier position for his particular pet; or may I add another class? I do so with much hesitation, and it is from your correspondence I arrive at the opinion: those who, perhaps too anxious to become great benefactors to their fellow ratepayers, and so earn their everlasting (parochial) gratitude, further some scheme, which may or may not succeed, become anxious about the success of their *protégé*, and, I may say, angry with those who appear, in all good faith, to differ from them.

Some five-and-twenty years ago we used to joke about the "golden dustman." But this gentleman has passed away. The place that knew him once—to wit, say, Paddington—knows him no more, and instead we have the "Golden Dust-bin"—sanitary, of course—in fact, to go through the correspondence which comes to hand daily through the favour of that invaluable institution of modern days, the Newspaper Cutting Agency, it would appear that, thanks to the inventive genius of our destructor makers, the "age of gold" has dawned upon us, and a veritable Klondyke is at our back doors.

So far as my individual opinion is concerned, I was under the impression that that was pretty well known, having erected the first destructor built in the South of England in 1882-3 (the second was Southampton in 1886). I at once utilised it as a steam producer, and have continued to do so up to the present time, and a most valuable adjunct to the sanitary appliance of Ealing it has been during all these years; dealing not only with the house refuse, but with the *sewage sludge* of a continually growing population, and that without the slightest difficulty or nuisance in any way. As is well known, the Ealing destructor is of the "Fryer," or low temperature type, assisted by my "Fume Cremator" of 1885, and which, notwithstanding Mr. Watson's criticism in the lecture at Gloucester, most certainly made the "destructor possible." These words are not my own, but were used by Mr. Laws in the paper he read at the International Congress of Hygiene (London) 1891, and I cannot help saying that it does strike me as somewhat strange that between the years 1885 and 1897 so little has been done by our engineering world in the way of supplying a really useful and economical apparatus for dealing with the question of house refuse. In making this remark I do not for one moment seek to depreciate the high temperature installation, nor suggest that Mr. Watson and others who are advocating their particular furnaces are acting other than in all good faith; on the contrary, I am free to confess that I am always deeply interested in the work being done, and particularly the statements which ever and again find publication from the pen of Mr. Watson, but nothing that I have yet heard, seen, or read has led me to change my opinion that for general use the inexpensive low temperature destructor, such as the "Fryer" of Manlove & Co., or the "Perfectus" of Goddard, Massey, and Warner, are other than the most suitable.

One of your correspondents refers to the statistics in my book on "Refuse Destruction," 1894, making particular reference to Table A., "Towns of England," where, out of a number of towns given as 1,005, 863 were under 25,000 inhabitants, and probably a very large proportion of these have no call for "power," although they may make a valuable asset of a well-burnt clinker and the ash from the hearth for building purposes. No doubt the view I take of them as a municipal officer is primarily the necessity for getting rid of a universal nuisance (house refuse) in a simple and efficient manner; the question of profit is a secondary one, and from this point of view, in my humble opinion, the low temperature furnace is the most likely to accomplish the object and meet the necessities of not the large towns, maybe, such as Leeds, Oldham, and similar centres of very large population, but of the towns which, comparatively insignificant when compared with the above, still just as much require the application of fire to deal with their sanitary nuisances.

Reference has, I know, been made again and again, in the general discussion of this question, to the supposed failure of the Edinburgh destructor. It may appear somewhat venturesome to state that, in my opinion, the Edinburgh destructor was not a failure, and this I do notwithstanding the fact that the Horsfall Company was called in to alter it. I visited Edinburgh twice, at the request of the Corporation, and from exhaustive examination I came to the conclusion that the fault was not in the destructor, but in the mode of working it. A guarantee had been given to destroy a certain number of tons per 24 hours, and the quantity was got through, with the result that the residue was not good hard burnt clinker, but a soft three parts burnt material, certainly unsatisfactory in its result. The experience of Mr. Yabbacomb at Bristol was very much the same; in his paper read at the meeting of the Municipal and County Engineers, September, 1896, referring to the work of the destructor ("Fryers") he says: "That by working all seven days, the amount specified in the contract with the manufacturers could be just reached; but the clinker was of a soft inferior character, through the fires being drawn too rapidly." Subsequently Mr. Yabbacomb applied a steam blast, with the result, a higher temperature, an increased consumption of refuse, $7\frac{1}{3}$ tons per 24 hours, together with an improved clinker, a conclusion I consider in every way satisfactory, and going to prove that, with careful working, an every-day result of a most satisfactory character may be obtained from the comparatively inexpensive low temperature furnace of the "Fryer" class, even when worked in the most moderate "work-a-day" mode.

I am quite aware that from the contractor's and patentee's point of view the low temperature furnace, even when a fan is added, is not a success; there is no special profit to be made out of these, and no patent fees; anyone is at liberty to build them, and for a few hundred pounds an installation equal to the ordinary necessities of a small town population can be erected; in making these remarks, I would again repeat that I am dealing with the smaller towns, and not with the large centres of population. At the same time, having erected the majority of our cells at Ealing without a contract and with our own men, I know the exact cost of construction.

With respect to the Shoreditch destructor, or "universal utiliser," as it has been termed, I can only say that I am content to wait; there is an old saying that "It is never safe to prophecy unless you know," and I cannot help thinking that very much of the feeling engendered in the minds of the Shoreditch chairman and others, has just been the result of "premature prophecy." So far as "thermal storage" is concerned, there is nothing particularly new about that; but its application to destructor purposes is new and interesting. To me, personally, I may say it is especially interesting from the fact that some years since Manlove, Alliott & Co., called my attention to the scheme, and I went into the matter with a view to its application at Ealing, but upon full consideration of the cost to be incurred, with the probable results, I came to the conclusion, to use a common phrase, that the "game was not worth the candle;" but in all fairness let me say that a scheme which might not be suitable for Ealing with its then 25,000 population, might develop results quite different in a district like Shoreditch with its 124,000. Should it succeed I shall be the first to "take off my hat," and acknowledge its merits, indeed, I think I may say that I will do so if it only accomplishes *one half* of the prediction made in its favour at its birth. I do not mean at the banquet, Mr. Editor, that would hardly be fair, you know, but rather between the times when the good Vicar of Shoreditch "read an appropriate dedicatory prayer," and the hour when "the light of other days" was turned down, and amidst the hearty applause of the company the chairman switched on the "light of the future." I am copying from printed account of proceedings.

I have no doubt that ere long a clear and exhaustive account will be forthcoming, showing the Dr. and Cr. state of the whole affair. I should have concluded this somewhat lengthy letter at this point, but for the fact that the morning post brought me in unmistakable print the announcement of another wonderful discovery in the destructor world. *London* informs me and all its readers that "Leyton is again distinguishing itself." In large letters we are informed that "The First Sludge Destructor" has been erected: "A Difficult Problem Solved by the Leyton District Council—A Combined System for Destroying Sewage Sludge as Well as House Refuse," and further, that the council has "proved that the sludge can be burned like ordinary house refuse," and further, that "on the advice of the surveyor, Mr. Wm. Dawson, the District Council made the first attempt *ever tried*, and the result of 15 months' working is sufficient to justify some show of pride." *London Argus* contributes similar information. I read these extracts at first with some amusement, it looked like a monstrous joke on the part of the surveyor to the Leyton District Council, but I took up another cutting and found that Sir Douglas Fox and Francis Fox had reported as follows: "So far as *we* are aware, it is the only form of furnace yet adopted, capable of burning a considerable portion of sewage sludge even when containing as in this case, a high percentage of moisture," and after reading this, I could not but feel ashamed for any professional man, shall I say brother municipal officer, who could allow such absolutely misleading and erroneous statements to go forth to the public, and I am sure that the same feeling will fill the minds of one-half of the municipal engineers of England, when they read them. I was under the impression that I had been burning the sewage sludge of Ealing with the house refuse, ever since 1883, and that most of the municipal engineers of England knew it, I thought that the Ealing works, visited by hundreds of visitors from not only England but from all parts of the world, had one speciality, viz., *burning the sewage sludge*. I was under the impression that the late eminent scientist, Dr. Meymott Tidy, in a lecture at the Society of Arts, April, 1886, said: "To my mind the destructor has reached its highest state of perfection at Ealing from the great thought the surveyor, Mr. Jones, has given to it. The sludge is there mixed with house refuse and burnt. Mr. Jones's view is that every town produces sufficient house refuse to burn the sludge." I thought that in the discussion that ensued upon the reading of Mr. Dibdin's paper on "Disposal of Sewage Sludge," before the Institution of Civil Engineers, as long ago as 1886, the subject of sludge burning was well threshed out, and stranger still, I was under the impression that the surveyor of Leyton—a member of the Incorporated Association of Municipal and County Engineers, of which I have the honour of being a past president—knew the Ealing works well, with all their specialities. All the above only goes to prove how strangely one may be mistaken.

I have upon my recollection the fact that *London*, to which I have referred, among the other items of interest respecting Ealing, says (April, 1895): "It (Ealing) discovered that the proper treatment of its dust and sewage not only gave health advantages such as no neighbouring area possesses, but placed at its disposal what might be called advantages for securing other advantages. *The collected refuse, which is mixed with the sewage sludge and consumed in the destructor cells, and the fume cremators produce tremendous heat, a portion of which had already been used to raise steam for driving the engine of the sewage works, &c.*"

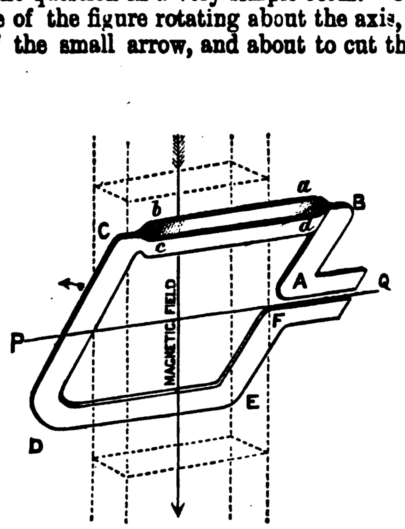
Mr. Editor, I had no intention of so extending my remarks, and I have omitted to touch upon many interesting details, as to residuum, cost, &c.; but reading at the last minute the details concerning Leyton, has led me into a somewhat extensive communication, for which I must apologise.

Charles Jones, M.I.C.E., F.S.I.

Ealing.

Mr. Alfred Still, in your issue of last week, observed that I, not understanding how it is that a buried conductor is free from eddy current heating, had "missed the point." This is perfectly true, and my desire to find it was largely my reason for stating so precisely the mechanism of the action of a slot-wound conductor. But Mr. Still does not assist matters by repeating an unsatisfactory explanation. He says, "surely we are right in assuming that, for a given E.M.F. generated" (I presume in the main dynamo circuit), "the eddy current loss in a conductor depends upon the time which it takes in passing into or out of the uniform magnetic field under the poles." I think we certainly are justified in the assumption, but if the conductor is moved faster into the field the eddy current loss is thereby increased, not diminished. Again, "the explanation given being that whereas in a smooth core armature the conductors enter and leave the magnetic field gradually, taking an appreciable time to do so; in the case of a slotted armature the lines snap across the conductor so quickly that the eddy current losses are necessarily very considerably reduced." He disclaims the form of expression of this explanation, but appears to accept the sense of it. If I understand what is meant, it is certainly wrong. The heat developed in a mass of metal carried across a single line of force, or isolated group of lines, is proportional to the speed, and the quicker it is carried the more it will be heated.

At the risk of again incurring Mr. Still's contempt, I will try to put the question in a very simple form. Consider the metal frame of the figure rotating about the axis, P Q, in the direction of the small arrow, and about to cut the magnetic



field shown by the dotted lines. Current will be generated in the circuit, *a b c d*, analogous to the eddy currents in an armature bar, while current generated in the frame, A B C D E F, is analogous to the main dynamo circuit. The electromotive force in the dynamo circuit due to the movement of the compound bar, B C, is the mean of the forces generated along *a b* and *d c*; and the electromotive force in the circuit, *a b c d*, is the difference of the forces along *a b* and *d c*. For the discussion of eddy currents suppose the main circuit to be open, and consider the passage of the closed circuit, *a b c d*, across the field. If *n* lines of force are threaded through a closed circuit at an uniform rate in a time, *t*, the heat developed is proportional to $\frac{n^2}{t}$, and increases with the speed. In a slot wound armature the bars never enter a strong field at all, and *n* is exceedingly small.

On the other hand, it is not necessarily the case that the bars pass from the interpolar space into the maximum or uniform field more quickly in a slot wound than a surface wound armature. If the two revolve at the same speed, and in fields of the same form, the time occupied in passing into the field will be the same. But in a slot wound armature the gap between the iron surfaces is less than in a surface wound armature, the fringing is less, the bar enters the field more suddenly, and the heating is to that extent increased.

Mr. Still's explanation appears to me to show that slot wound conductors should heat more than surface wound conductors.

The solution of the difficulty lies clearly in the small intensity of the maximum field, not in the rate of speed at which the bars enter that field.

As to my paradox. Mr. Still's case is not parallel at all. A dynamo when running is a seat of electromotive force, not necessarily a source of current; and our conception of its action is not dependent on its always producing current. A magnet, on the other hand, is not a seat of magnetic force, but a source of magnetic flux, and we have no conception of its existence other than as giving rise to magnetic flux. The question is this: Place a permanent magnet, *i.e.*, a body whose sole property, in so far as it differs from a piece of hard steel, is that it is a source of flux, in a position where no flux is possible. What happens? The consideration of a dynamo running, but not generating current, does not bear on the point.

W. A. Price.

Is an Electric Traction Engine Subjected to Shocks, or is it Not?—Raworth v. Emery.

In your issue of October 29th, 1897, you published a letter of mine criticising Dr. Emery's article on "Engines for Electric Railway Power Stations," which appeared in the *Street Railway Journal* of the same month.

With this letter of mine the *Street Railway Journal* was deeply grieved, and in its December number devoted more than a column to the expression of its sorrow that an English engineer should have chosen to write in an ill-natured way about a purely technical subject, and should have attempted to arouse personal or international prejudices.

Of course, nothing was further from my mind, for some of my best friends engaged in the engine trade are Americans, and I regret as much as the *Street Railway Journal* that my letter was open to any such interpretation, and especially do I regret now that we are informed that Dr. Emery is an international authority on the steam engine, that I took the liberty of criticising his literary peculiarities; and I feel sure Dr. Emery, with the usual breadth of mind of an engineer, has already forgiven me.

Dr. Emery has written a letter, in which he endeavours to defend his position, and to destroy mine; I, therefore, propose to submit his arguments to the judgment of your readers.

The original article stated, concerning an engine for electric traction: "Its entire construction must be proportioned to the racking due to continued repetition of shocks," to which I replied: "This oft repeated fallacy would be amusing, were it not for the fact it is too often believed, and worse still, acted upon, whilst all the time the fact remains that *there are no shocks and no excessive strains*."

Now for Dr. Emery's arguments:—

First, he says I "must know that if a dynamo directly connected to an engine be short-circuited, its speed is naturally checked by a load applied with lightning rapidity. Necessarily the fly-wheel tends to twist the engine shaft, and all the moving parts are brought up with a shock, instead of being changed in direction smoothly by a crank motion."

I am sorry to say that the doctor presumes too much on my knowledge. I certainly do not know "that a short circuit tends to twist the engine shaft," although I am quite willing to admit that it tends to twist the dynamo shaft and the coupling.

Further, I do not know "that all the moving parts are brought up with a shock instead of being changed in direction smoothly by a crank motion." No short circuit ever did or ever will bring up an engine in less than half a revolution.

I hope this statement is quite clear. I do not wish to take refuge behind any ambiguities.

Dr. Emery then proceeds with his second argument:

"Again, in releasing a load suddenly, the elasticity of the parts and their weight also produce shocks, as every piece of metal transmitting the load is, within certain limits, a spring."

When the Doctor penned this sentence he evidently forgot that the throwing off of the electrical load does not open the exhaust valve of the engine, and that, therefore, the parts continue under the stress of the steam pressure until the end of the stroke, when they are "smoothly changed in direction by a crank motion."

The above are all the arguments Dr. Emery adduces which are applicable to English electric lighting or traction engines. He concludes, however, with one which applies to some American engines, though not to those which have been sent to this country:—

"Again, if there be any side strains due to overhanging cranks not balanced in one bedplate, the amplitude of the lateral movements caused thereby will be proportioned to the time in which the maximum force is applied; that is, they will be greater for heavy loads than for light ones."

Here again the Doctor is wrong.

It would be a very bad engine that moved laterally $\frac{1}{16}$th of an inch; therefore, with a cut-off of even $\frac{1}{10}$th, there is ample time for the full movement to occur, and, as a matter of fact, anyone with eyes may see the result for himself; at every stroke, on the opening of the admission valve, the cylinder goes over with a snap, there is no appreciable time element.

It is rather unfortunate for the other side that they have got such an honest advocate as Dr. Emery, who has tried to rake up every plausible looking argument in support of their theory, for we now know the nakedness of the land; we also know that the lean kine are eager to eat up the fat kine, and they will do it if we do not bestir ourselves.

The *Street Railway Journal*, in its backing up of its contributor, goes one better than Dr. Emery. It says:—

"It was no unfrequent occurrence to see an engine brought up standing by a heavy load suddenly thrown on with the starting of a number of cars."

Now, what does the phrase "brought up standing" mean? Most electricians are aware that, as the speed falls, the volts fall also, and that the engine will still run at a reduced speed. If the *S.R.J.* means to convey the impression that the engine stops dead, then I say it has been dreaming, if on the other hand it simply desires to indicate that the engine was too small for its job, why does it not reproduce Mr. Philip Dawson's paper for the education of its readers?

John S. Raworth.

Electro-Motors and Fire Office Rules.

The latest rules issued by the Fire Office Committee, a representative and executive body, imposes restrictions upon the construction of electro-motors which, if not modified, will seriously interfere with their use. In fact, the new rules seem to favour one type of electro-motor to the degree of being a broad advertisement for it.

The rule in question enjoins that a "fireproof case which shall form part of the designed construction of the motor itself, and not be an added movable covering," shall in all cases be used. Electro-motors enclosed by a case forming part of the stator are necessarily hampered in construction and of less efficiency than those of ordinary make. It is fair to suppose that the Fire Committee have in view the extreme inflammability of minute particles, especially of organic matter, such, for instance, as flour dust. In a well constructed and carefully tended motor, the ordinary sparking is not sufficient to ignite such particles, and in the case of a short circuit the motor would come to rest long before any part of the burnt-out insulation could be spread by centrifugal force.

Again, in applying electro-motors to the direct driving of machines of small power, the enclosure of the whole in a case not only renders the mechanism more subject to derangement, because a single fault is not observed at the time of occurrence, but also conduces to excessive heating by checking natural ventilation. This is most important in the case of intermittent loads as a free current of air tends to keep the varying temperature within a certain safe limit. A movable box with mica lights may be used in certain cases to enclose the commutator, but in the event of excessive sparking, this method is more dangerous than the ordinary open working, since the confined space would, after some time become filled with infinitely finely-divided metallic particles, the natural result of attrition, finally causing a revolving arc to be formed, quickly destroying the motor, and probably causing a destructive fire.

As small electro-motors are favourably received by manufacturers and the public generally wherever an electric service obtains, it is a pity that the electrical trade should be checked in this direction by the introduction of rules which may be modified without increasing the fire risks.

The Fire Committee, as a representative body so far as the fire offices are alone concerned, do not represent the public, or the electrical trade, and evidently require technical assistance when making their rules.

Fredk. Walker.

February 2nd, 1898.

BUSINESS NOTICES, &c.

Bankruptcy Proceedings.—A receiving order was made last Tuesday, at the London Bankruptcy Court, against John Dewhurst, electrician, &c., 52, North End Road, West Kensington. The debtor presented his own petition, and an order of adjudication was also made by the Registrar. No particulars transpired regarding assets or liabilities.

Electrical Work in Natal.—We understand that Messrs. Mowat & Still, of Pietermaritzburg, Natal, in view of the amount of electrical work now coming on in that city, have opened a branch in their extensive business for electrical engineering, under the management and advice of Mr. Oswald R. Swete, A.I.E.E. (vice-president of the S.A.Soc.E.E.). We understand that the firm are open to receive the latest catalogues of electrical fittings and other appliances.

For Sale.—In an "Official Notice," will be found particulars of two sets of secondhand electric lighting plants, which are offered for sale by the City Electrical Engineer at Liverpool. The plants are suitable for a large and small private house respectively.

Messrs. Montagu Kent & Co., will on the 10th inst., sell by auction, various electric light plants, dynamos, boilers, steam and gas engines, shafting, lathe, planing machines, one electric and three steam launches, at Strand-on-the-Green, Chiswick. See our "Official Notices."

Hospital Lighting.—The Metropolitan Asylums Board have decided on the recommendation of the Northern Hospital Committee to engage an engineer, or a firm of engineers, to prepare a scheme for lighting the hospital, and to draw up specifications, plans, &c. Messrs. Burstall & Monkhouse have already reported upon the cost of electric lighting plant, which they estimate at about £10,350.

Liquidation Notices.—An account of the winding up of the Guattari Power Syndicate will be placed before the shareholders by Mr. A. J. Bale, liquidator, at a meeting to be held at 120 and 122, Newgate Street, E.C., on Tuesday, March 1st, at 2 o'clock.

At meetings of the National Company for the Distribution of Electricity by Secondary Generators, held January 11th and 28th respectively at 2, Warwick Street, Regent Street, W., resolutions were passed winding up voluntarily, and appointing Mr. J. H. Thornton, of Winchester House, E.C., liquidator.

The Affairs of an Electrical Company.—On Wednesday, before Mr. Justice Wright, sitting as an additional judge of the Chancery Division, among the winding-up petitions which appeared in the list was one in the name of Mr. H. O. Ruelle, relating to the National Company for the Distribution of Electricity by Secondary Generators, Limited. On the case being reached, Mr. Rowton said this was a creditor's petition. The matters at issue between the company and the petitioner were the subject of litigation before Mr. Justice Stirling. They were before him on last Saturday week, and on an intimation from his Lordship, certain terms were then arranged, which included that the petitioner should adjourn the hearing of the present petition. He had, therefore, to ask that the matter should stand over generally, with liberty to apply for it to be restored to the list. His Lordship granted the application.

The Electrical Metal Working Syndicate, Limited.—We are informed that Messrs. Scott Anderson & Beit, of Royal Insurance Buildings, Sheffield, have been appointed sole agents for the Voltex process of electric welding, brazing, &c., for the following counties:—Yorkshire (south of a line through Whitby, Northallerton and Richmond to Kirkby Stephen), together with the entire counties of Lancashire, Nottingham, Derbyshire, Staffordshire, Cheshire, Worcestershire and Warwickshire.

Water Power on Tender.—The chief Engineer for Irrigation, Madras, is inviting tenders, by order of the Secretary of State for India, until July 1st, 1898, for the utilisation of water power of the Periyar Lake.

ELECTRIC LIGHTING NOTES.

Bath.—The bill for the quarter's public electric lighting amounted to £516, and when this was before the Surveying Committee last week Alderman Sturges drew attention to the deduction of £27 for 108 failures at 5s. This he said did not mean that there had been 108 distinct failures in the lamps, but that on one occasion through a fault in the machinery a whole line of lamps went out. Was it a righteous thing, he asked, to deduct for 108 failures under those circumstances? The bill was passed without the deduction.

Bedford.—Consumers are agitating for reduced charges for current and lower meter rentals. The Electric Light Committee is to report on the desirability of constructing a refuse destructor at the supply works.

Birkenhead.—The Electrical Committee submitted to the Council, on Wednesday, a report dealing with their department. This report states that in February, 1894, the Council appointed Mr. James N. Shoolbred, M.I.C.E., as electrical engineer and adviser, and the supply of electrical energy commenced in September, 1896. Since, the undertaking has proceeded somewhat slowly, but on the whole satisfactorily. An index of the progress is afforded by a table showing the number of consumers during the quarter ending December 25th, 1896, and the quarter ending December 25th, 1897, the figures being—Consumers, 66; and current in units, 23,543, during the latter quarter, as compared with 23 and 6,635, the figures for the first quarter of the undertaking. A sub-committee has considered the constitution of the present electrical staff and the possibilities of the more rapid development of the undertaking, and the supply of energy for power as well as lighting, especially in connection with the working of tramways, and the result of their consideration is a recommendation to dispense with the services of the consulting engineer on the completion of the various contracts under his supervision, and to appoint a resident electrical engineer, at £300 per annum, to direct the further development of the electrical supply.

Birmingham.—In a recent report the Gas Committee make some remarks regarding the past and prospective effect of electricity supply upon the gas consumption. They consider that there is nothing to suggest that "it will not be necessary" to extend the gas works in order to meet the demand. The total sale of electricity in Birmingham, in 1896, is given at "not more than equivalent to a sale of 60,000,000 cubic feet of gas as ordinarily used for lighting purposes. This would not, even if it had all been used in substitution for gas, displace plant for the production of more than 350,000 cubic feet of gas per diem. The electric lighting of the Market Hall has only diminished the consumption of gas registered in that building from 8,600,000 to 6,900,000 cubic feet per annum. The greatest daily output of gas in Birmingham in 1896 was over 33,000,000 cubic feet, and the total sale in the year was 4,859 million cubic feet. The effect of the competition in Market Hall Ward, where electricity has met with the largest sale, shows a slight decrease in the sale of gas for 1896, as compared with 1892, but an increase in 1897 over 1896 of 3·6 per cent. in the central area, and 13·6 in the rest of the ward. In other large towns and cities where electricity has made progress, an increase has taken place in the gas wanted, this being shown by figures."

Blackpool.—The need for extending the Corporation electric lighting system was before the General Purposes Committee last week. It was stated that the present plant was all taken up. They had no reserve, and the committee could not undertake to supply any more customers, although they had many large applications, including the new Alhambra, the Hotel Metropole, and the arc lighting of several more streets in the town. It was proposed to spend another £40,000, and to put down a new engine of great capacity. Several of the members complained that sufficient time had not been given to carefully consider the matter and the electrical engineer's suggestions. The Committee approved of the expenditure. It was stated that the necessary machinery had been provisionally secured, as engineering firms would not undertake to fulfil further orders in less than two years.

The Town Council on Tuesday adopted the proposed scheme for the extension of the electricity works at a cost of £40,000. Application is to be made to the Local Government Board.

Bradford.—The shops and warehouses comprising Borough Mills, Manchester Road, are now supplied with the electric light from a special plant which has just been put down. There are about 30 tenants on the premises, and provision is made for about 1,000 16-C.P. lamps. The installation, which was put in by Messrs. A. J. Harris & Co., comprises two dynamos, each to supply 350 lamps, and 55 Epstein cells, for 400 lamps. It seems that a company works the concern, each consumer taking a share in it, so that the cost should be very low. The cells are charged by a motor transformer during the day.

Bristol.—A Local Government Board inquiry was held on Tuesday into the application for a £23,000 loan for the extension of street lighting in the city. It was asked that the sanction should be given as speedily as possible, as it is desired to push on with the scheme.

Burnley.—A Local Government Board inquiry was held last week *re* an application by the Corporation to borrow £25,000 for electric lighting. The Town Clerk said that four years ago the electric lighting installation was started, and the loans already sanctioned amounted to £29,756. With the additional borrowing powers they would be able to extend the plant and the mains into the out-districts of the borough.

Cardiff.—A Local Government Board inquiry has been held into the Council's application for a £29,500 loan for electric lighting. Mr. Applebee, the electrical engineer, showed the progress of the undertaking, for which £59,835 had been borrowed, and he explained the extension proposals.

Colombo.—The Indian papers give particulars of the proposal of Messrs. Boustead Bros., which has been accepted by the Colombo Municipal Council, for the electric lighting of Colombo. The firm will replace 548 gas lamps by 548 60-C.P. incandescent electrics, erecting lamp-posts, overhead mains and feeders, &c., &c., for Rs.25,000 (or Rs. 45·62 per lamp), or an annual payment of Rs.2,250. Current will be supplied to the lamps at the rate of 200 hours per month including renewals, maintenance, &c., &c., for Rs.30,000 per annum, which is about 15 cents per unit, or Rs.54·74 per lamp per year. The contract is for five years, after which the municipality can take over the street installation at a valuation. Private consumers will be charged not more than 50 cents per unit (7¾d.). The engineers have a sly dig at the City of London Electric Lighting Company, for they add "In the City of London a company has the monopoly of supplying current at 8d. per Board of Trade unit." Yet even at Colombo it can be profitably done for ¼d. less!

Crieff.—Mr. Yorke's proposals *re* electric lighting were again before the Town Council last week, and there was a discussion on various points, but the matter was delayed until a conference between that gentleman and the Council could be arranged for obtaining further information.

Darfield.—A special meeting of the District Council will be held on March 4th, to decide whether to apply for an electric lighting provisional order.

Dundee.—Panmure Street Congregational Church has been lighted by electricity, the congregation subscribing the money.

Edinburgh.—The street lighting extensions, to which we referred last week, have been agreed to by the Town Council.

Edmonton.—The Board of Guardians' Works Committee is to report on the advisability of supplying the electric light to the Edmonton House and Chase Farm Schools.

Exeter.—In a report to the City Council a Committee state that they have no data on which to estimate the cost of electrically lighting the main streets, but inasmuch as part of the first cost of arc lamps and posts would have to be paid, and the positions of some of the lamps were to be changed, they had allowed for an increased estimated expenditure of £400.

The electric lighting undertaking is going on satisfactorily. The number of lamps has increased from 7,400 to 10,000, and orders are coming in faster than they can be supplied.

Finchley.—Up to the present the Council has refused to support any electric lighting scheme, but they have now informed a correspondent that they will give careful consideration to any proposal he may make.

Hull.—The electrical engineer, Mr. Barnard, has submitted the following estimate of income and expenditure during 1898:—Expenditure: Generation of current, £3,100; distribution of current, £350; repairs, renewals, and maintenance, £1,100; management expenses, £1,175; insurances, £150; rents, rates and taxes, £950; interest on capital, £1,985; payments to sinking fund, £1,470; balance, being profit, £970; total, £11,250. Income: Sale of electricity, £10,830; meter rates, £420; total, £11,250.

Ilford.—The Council is to approach the Great Eastern Railway Company with a view to the purchase of a piece of land adjoining Sylvan Road for an electricity works site.

Kendal.—In December the Council decided to communicate with experts in gas and electric lighting matters on the lighting question, but as nothing has been done there is a feeling that there has been unnecessary delay on the part of the Gas and Water Committee. At the last Council meeting it leaked out that the electric lighting matter had lapsed through inadvertence. Letters had been received from experts, but had been misplaced and could not be found. The Town Clerk is communicating with the experts again.

Leamington.—The Midland Electric Lighting Company, Birmingham, are stated to have unconditionally withdrawn their Bill for power to light the Borough by electricity. Some time ago the Corporation commenced the promotion of a Bill on similar lines, and it is now stated that the Midland Electric Lighting Company have withdrawn in order that they may be the better enabled to oppose the Corporation scheme. The company have large works in Wise Street, but up to now the demand for electricity has not been by any means equal to the supply. It is stated that the cheap rate at which gas is supplied has militated against a general adoption of electricity in the Borough.

London, E.C.—The Court of Common Council has referred it to the Streets' Committee to consider and report forthwith as to the desirability of applying to the Board of Trade for an electric lighting order to enable the Corporation to supply electric light within the City from a station to be established by themselves or otherwise; and also to report as to the practicability of generating electricity from steam raised by burning the City's refuse in specially constructed furnaces in such proposed electric light station.

Merthyr Tydfil.—The Board of Trade has revoked the 1896 electric lighting order, as and from January 24th, 1898.

Penzance.—The Municipal Electric Supply Company has laid a scheme for lighting the town before the Council. The idea is for the undertaking to be "substantially municipal," the entire responsibility of capital expenditure resting on the company until the Council takes it over. The same system as employed at Brighton is suggested. Referred to the Lighting Committee.

Peterborough.—The Board of Trade has sent to the Council for any observations which they may wish to offer, a description of the system in the form in which the Board propose to approve it, subject to their regulations for securing the safety of the public, and for ensuring a proper and efficient supply of energy. The system to be adopted is described as follows: For general purposes. A continuous current direct supply at constant pressure, and the three-wire system, the mains being partly continuously insulated cables drawn into iron pipes or earthenware conduits, and partly bare copper conductors laid in earthenware or concrete conduits. The Lighting Committee has adopted the Board's suggestions. The application of the Peterborough Electric Light and Power Company for a provisional order is being opposed.

The Local Government Board inquiry will be held on Tuesday, February 8th, regarding the £15,000 loan. This is the second inquiry.

Shoreditch.—At the Vestry on Tuesday last Mr. H. E Kershaw, Chairman of the Electric Lighting Committee stated:—"That owing to the unprecedented success of the Vestry's efforts in the combined scheme of the generation of electricity from the steam supplied by the dust destructor, the Committee recommend the Vestry to reduce the charge for electricity from 6d. per unit for the first two hours and 4d. per unit for the surplus, to 6d. per unit for the first hour and a half and 2d. per unit afterwards. This will work out to consumers of electricity using the light for three hours per day at 4d. per unit, four hours per day at 3½d. per unit, six hours per day at 3d. and so on reducing the cost in proportion to the number of hours the light is in use. This, I believe, is a record in municipal electric light undertakings. After existing for six months only, we are supplying electricity, within a little, as cheaply as any municipal installation in the country. During the past quarter we have sold 95,000 units of electricity, and the engineer's estimate for the current quarter is 150,000 units. The Committee feel extremely gratified that their efforts have been attended with such marked success, fully justifying what has been repeatedly termed a most expensive and dangerous experiment, and for the benefit of the many municipalities who are watching this scheme, though we do not feel called upon to issue our statistics until the end of the first financial year (June 30th) we are satisfied that our expectations will be more than realised, and the success of the joint scheme most *thoroughly established*." After discussion the Vestry resolved to defer the Committee's recommendations till after the financial year's statement in March.

St. Albans.—The Herts County Council will oppose the St. Albans Electric Lighting Order, 1898.

Ventnor.—Plans for the electric light station in Newport Road have been passed by the Council.

Walsall.—A Local Government Board inquiry was held on 28th inst. into the Corporation's application for borrowing certain monies, including £7,000 for electric lighting. The Town Clerk, referring to the growth of the electricity undertaking, said that in 1896 there were lamps of 5,704 C.P. connected, but in 1897 there was the equivalent of 8,195 C.P. The increased demand necessitates an increase in the size of the engine room, and to put in one 250-H.P. engine and a dynamo. There will also be two additional transformer stations, mains, &c., and the present capacity will be doubled.

Watford.—In February, 1894, the Local Board gave Mr. F. Downer permission to carry an electric wire from his etching rooms to his private residence. It is understood that Mr. Downer is supplying a neighbour with current, and the Electric Lighting Committee now recommends that he be requested to give an undertaking that he will limit the supply of electric light to his own premises as soon as the Council is prepared to supply the light.

West Hartlepool.—A site has been secured for the electricity works, in the vicinity of the paper works. The low tension continuous current system has been adopted.

Westgate-on-Sea.—The application of the Isle of Thanet authorities for an electric lighting order is being strongly opposed as regards Westgate-on-Sea.

Wigan.—Before proceeding with the electric lighting scheme, the ratepayers within the proposed area are to be canvassed.

Willesden.—The application of an Electric Lighting Committee for a provisional order is opposed by the Council.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

Argentine.—The rumour that appeared in some of the London papers to the effect that the directors of the Anglo-Argentine Tramway Company were contemplating the adoption of electric traction, is contradicted by the *Review of the River Plate*, though that journal considers the company will have to move in that direction before many years have passed, or lose their traffic.

Bradford.—On Wednesday the Tramway Committee met to deal with tenders for rails, paving, electric wires, cars and car-sheds and all the other appliances needed for the electric tramways.

Bristol.—On 26th ult., the Bristol Tramways and Carriage Company's Parliamentary Bill authorising the use of electrical power was laid before the shareholders, and unanimously approved. Correspondence which had passed between the Council and the company respecting the former body's proposal to purchase the undertaking was read. Mr. G. H. Low, the chairman, in going into the matter of electric traction and the advisability of employing such on the proposed extensions, said that several of the contemplated extensions were to traverse roads which were so steep as to make them practically inaccessible for horse tramways, but with electricity they could deal with districts hitherto unprovided for. He referred to the company's relations with the Corporation in 1896, *re* the supply of electric power for the tramways, since which date the gentlemen who took a prominent part in endeavouring to force their supply of current upon the company, had been assuring the ratepayers that come what may they must have electric traction. On the point of the overhead trolley system being the most practicable form, there was no difference of opinion between the company and a majority of the Council. The company was not seeking to enter into competition with the Corporation, but, he proceeded, "we, having an established business, are simply asking for authority to carry on our business and for the purposes of running the remainder of our cars by electricity, to generate and apply our own electricity, as we are already doing in connection with the working of seven or eight miles of tramway within the city of Bristol. We are at the present moment generating for our own purposes at a station within the city and county of Bristol more electrical current than the Corporation turn out for the whole of their customers and their street lighting, and we have the plant there already installed to enable us to make a much larger output. In addition, we were only last session authorised by Parliament to convert our extensive depôt at Eastville into a generating station, and we propose to acquire waterside premises at Counterslip also for the purposes of a power station. I do not believe for one moment that a Parliamentary Committee will prevent the citizens of Bristol from securing the advantages of electric traction over the present horse lines simply because another trading concern, namely, the Corporation of Bristol as owners of lighting works, put forth a plea that we should be forced to bolster up their undertaking as a condition to this improved form of traction being given to the public. So far as your directors are concerned, they are as determined as ever in their intention to resist to the uttermost such an attempted interference in the company's business, and no circumstances have occurred since our original decision on this point to weaken us in the slightest degree, but rather to the contrary." Regarding the purchase question, he remarked that the right of purchase by the Corporation arises in connection with the horse lines about 15 years hence, though as to the main portions of the electric lines there is no right for 21 years.

Crewe Light Railway.—The Cheshire County Council and the Crewe Town Council appeared in opposition to certain of the clauses proposed by the British Traction Company in this Bill. The company, however, practically carried their scheme.

Dover.—The electric trams continue to be well patronised. During the week ended January 22nd, 25,890 passengers were carried, and a daily average of £17 19s. 7d. taken in fares. The total fares since the opening has been £2,265.

Electric Power Distribution Scheme.—Last Friday Mr. Devonshire (representing the British Thomson-Houston Company as chief engineer) addressed a number of manufacturers at the Swan Hotel, Mansfield, with respect to the proposed electric power scheme. He gave no quotations or terms for power at present, but could promise that it would be cheaper than steam.

Hastings.—Councillor J. J. Boutwood has been lecturing on "Electric Tramways" here, and his lecture was repeated at the Market Hall, on Wednesday, by request.

Hull.—We understand that, owing to the open specification, there was an enormous divergence in the tenders submitted for the electrical equipment of the Corporation tramways. The power quoted for varied from 466 kilowatts to 1,500 ditto; and the prices, of course, varied in a corresponding degree. Tenders were received from the following firms, viz., Mr. R. W. Blackwell; British Thomson-Houston Company, Limited; Brush Electrical Engineering Company, Limited; Crompton & Co., Limited; Electric Construction Company; John Fowler & Co. and Greenwood & Batley (joint); Laing, Wharton and Down; Lowdon Bros.; Mather & Platt; Thos. Parker, Limited; Siemens Bros. & Co., Limited; Simplex Electric Conduit Company; Westinghouse Electric Company, Limited. As we state elsewhere, Messrs. Siemens' tender has been provisionally accepted by the Works Committee, and their report was to come before the Council yesterday, Thursday, for confirmation.

Kirkcaldy.—The Ratepayers' Association is advising the Council to take up Prof. Kennedy's combined lighting and traction scheme, to which we referred last week. It is said that the present idea is to have 10 cars, five running in each direction.

Liverpool.—Sir Arthur Forwood, the chairman of the Tramways Committee, has prepared a report on the work of the tramways, with special reference to the question of low fares, and he recommends that for the electric tram system penny fares be adopted throughout the city, two-pence being charged for seats in the smoking compartment.

Middlesbrough.—The laying of the tramway rails in connection with the electric tramway from Thornaby to Middlesbrough has been completed, and the Highways Committee has voted £1,200 to the Imperial Tramways Company for wayleave.

New Cross and Waterloo.—We understand that this electric underground railway scheme is not to be proceeded with.

Newcastle-on-Tyne.—The City Council held its adjourned debate on the proposals in reference to the municipalisation of the tramways last week. The following resolution was passed:—"That in the next application to Parliament power be sought for the Corporation to work their own tramways; but that, until the scheme to be prepared by the recently appointed new Tramway Committee for providing the city with tramways has been considered by the Council, it is inexpedient to come to a determination as to whether the working of the tramways should be undertaken by the Corporation."

Ripon.—The Town Clerk is making inquiries as to the best means of providing a tramway—electric or cable—between Ripon Station and the market place.

The Power Distribution Schemes.—The Power Distribution Company has asked the Tipton Council to withdraw its opposition, on condition that the company agrees not to supply the electric light except with the Council's consent. A sub-committee will confer with the company and the other local authorities concerned.

The Ripley and Belper District Councils are among the latest bodies to oppose the scheme of the General Power Distributing Company.

The Darlaston General Purposes Committee recommends the Council to withdraw its opposition to the application of the Midland Electric Corporation for Power Distribution, subject to fair and reasonable conditions to secure economical terms to customers, and protective clauses in favour of the Council being inserted in the provisional order.

The "Underground" and Electric Traction.—In connection with the proposed employment of electric traction on the Metropolitan Underground, Mr. Bell, the chairman and managing director of the company made some important remarks to the shareholders last Friday:—"His anxiety had always been to see the Inner Circle worked first as an experiment by electricity. The departmental committee appointed by the Board of Trade to consider the ventilation question had arrived at certain conclusions, which were stated in the report. Although the committee had recommended various openings as a tentative measure, they had added a rider that if within three years from the passing of the Act authorising the openings, the company had not adopted electric traction, or other mechanical means of ventilation—which practically meant fans—some competent authority, to be stated by Parliament, should order the openings to be closed. That was if they were contumacious, which, however, no one could charge them with being. For the last 10 years the directors had had the idea of electric traction constantly before them. They all desired it, and they hoped they were on the high road to obtain it. Certain proposals were now under consideration, and he hoped that they would shortly be in such a condition that the directors could regard them as practicable. In that case they would immediately ask the shareholders for their approval. To enable them to be prepared for electric traction, Clauses 19 to 28 had been inserted in the Bill. The District Company were in accord with them in regard to electric traction. With respect to the question of ventilation by fans, they had tried fans, and he knew them to be a failure. He had expressed to the departmental committee his belief, after 25 years' experience of their railway, that electric traction was the solution of the problem they had been appointed to consider. The use of electric traction would involve entirely new stock."

Underground Electric for Brighton.—A Bill is to be introduced into Parliament next session, for power to form a company to construct an underground electric railway from a point near the station of the L. B. & S. C. Ry. Company, to a point under King's Road, but with openings under the parade communicating with the beach. The total length of the line will be 5 furlongs 17 25 chains. The capital of the company will be £120,000 with power to borrow £40,000 for equipment purposes. According to a financial daily, the maximum fare proposed to be charged is 2d. for the whole distance. The promoters names are Messrs. S. H. Doubleday, C. F. Webber, and J. W. Kersley.

Wallasey.—The District Council is about to take formally into consideration the desirability of taking over and working the local tramways, and also the question of employing electric power.

TELEGRAPH AND TELEPHONE NOTES.

Bedford Telephones.—A Committee is inquiring into the desirability of applying for a municipal telephone license.

Norwich Telephones.—At the Norwich Town Council last week there was a very lengthy discussion on the telephone system. Sir Harry Bullard, M.P., proposed that a petition be presented to the Postmaster-General to grant a municipal license, to be worked either by the Corporation or by a company approved by it; also that a deputation be appointed to present the said petition. The debate is to be continued at the next meeting.

The Direct West India Cable Company, Limited.—This company announces that its cables from Bermuda to Turks Island, and Turks Island to Jamaica, are now open for traffic, and that messages for these islands can now be sent at the rate of 3s. a word. The company draws attention to the fact that this is the only "direct" and all-British cable route to Jamaica and other West India islands (the other alternative routes being *viâ* the United States and Cuba, or the unsettled central American States).

CONTRACTS OPEN AND CLOSED.

OPEN.

Bilbao.—February 28th. The Secretary of State for Foreign Affairs has received a despatch from Her Majesty's Consul at Bilbao, reporting that the provisional board appointed in connection with the electric tramway which it is proposed to lay from Zumarraga to Zumaya, in the province of Guipuzcoa, invite plans and tenders, to be received by February 28th, for the construction and equipment of the line. Further particulars of the conditions of the tenders for the above-named tram line and branch, which together measure 30 miles, may be inspected at the Commercial Department of the Foreign Office any day between the hours of 11 and 6.

Belgium.—February 11th. The Provincial Government Authorities in Brussels are inviting tenders for an installation of electric lighting in the offices of the Governor of Brabant in the Rue de Chêne, Brussels. Tenders to be sent to the Gouvernement Provincial, Brussels.

Belgium.—February 16th. Tenders are being invited by the Société Nationale des Chemins de Fer Vicinaux, of Brussels, for the supply of 38 electric tramcars. Tenders to be sent to, and particulars may be obtained from, the offices of the company, Rue de la Science, 26, Brussels.

Berlin.—March 15th. The Municipal Traffic Deputation of the Town Council have opened a competition for the construction of several new electric tramways in that city. Exhaustive details concerning this project are contained in the *Elektrotechnische Zeitschrift* of the 13th inst., which mentions that proposals will be received by the Stadtische Verkehrsdeputation Rathhaus III, Berlin, by March 15th.

Copenhagen.—March 12th. The Frederiksberg Sporveis-og Electricitets Aktieselskab want tenders for steam engines, dynamos, accumulators and switchboards. Offices of the company, Gl. Kongevei, 140, Copenhagen.

Denmark.—March 12th. Tenders are being invited for the supply of the engines, dynamos, accumulators, &c., required in connection with the new central station at Frederiksberg, near Copenhagen. Tenders to be sent to the Frederiksberg Sporveis-og Electricitets Aktieselskab, Gammel Kongerie, 140, Copenhagen V., from whom particulars may be obtained.

Edinburgh.—February 5th. The Corporation want tenders for the wiring of the Police Station, Abbeyhill. See our "Official Notices" January 28th for particulars.

France.—March 31st. Tenders are being invited by the Municipal Authorities of Saint Chamond (Loire) for the concession for the lighting of the public streets of the town, either by gas or electricity. Particulars from, and tenders to be sent to, La Mairie de Saint Chamond (Loire).

L.C.C.—February 16th. The London County Council Asylums Committee want tenders for a great variety of sundries. One of the items is for electric lighting sundries for Claybury. Particulars at the office of the Asylums Committee, 21, Whitehall Place, S.W.

Madrid.—February 22nd. The Secretary of State for Foreign Affairs has received a despatch from Her Majesty's Chargé d'Affaires at Madrid, enclosing copy of a Royal decree announcing that a public auction for the contract for repairing the national submarine telegraph cables during the next five years will be held at Madrid on February 22nd. Further particulars as to the cables in question may be inspected at the Commercial Department of the Foreign Office any time between the hours of 11 and 5.

Redditch.—February 14th. The District Council want tenders for the supply of buildings, gas producing plant, gas engines, alternators, cables, transformers, &c., for the electric lighting of the district. Consulting electrical engineer, Mr. J. A. McMullen. See our "Official Notices" January 28th.

Rochdale.—February 19th. The Corporation want tenders for steam dynamos, balancer, and boosters, &c. Engineers, Messrs. Lacey, Clirehugh & Sillar. See our "Official Notices" January 14th.

Roumania.—March 15th. Tenders are being invited by the General Direction of the Roumanian Post and Telegraphs in Bucharest for the supply of 56,000 metres of galvanised iron and steel wire.

Spain.—February 11th. Tenders are being invited by the Municipal Authorities of Valderas (Leon province) for the concession for the electric lighting of the public streets of the town during a period of 17 years. Particulars may be obtained from, and tenders to be sent to, El Secretario del Ayuntamiento de Valderas (Leon).

St. Helens.—February 21st. The Corporation want tenders for various plant and machinery, &c., in connection with the proposed electric tramways. See our "Official Notices" January 28th for particulars. Consulting engineer, Dr. J. Hopkinson.

St. Pancras.—February 22nd. The Vestry want tenders for dry back marine boilers with superheaters and brickwork seatings. See our "Official Notices" this week.

The War Office.—April 27th. The Secretary of State for War is prepared to receive offers, competitive designs and specifications for the supply of portable electric search light apparatus. Particulars from the Director of Army Contracts, War Office, Pall Mall, S.W. See our "Official Notices" for particulars.

Victoria.—March 21st. The Telegraph Department of the Victorian Government Railways are inviting tenders for the supply of alternating current transformers and one main switchboard. Tenders to the Telegraph Superintendent's Office, Spencer Street, Melbourne.

CLOSED.

Bedford.—The Town Council has accepted the tender of Messrs. W. H. Allen, Son & Co., for the supply of a 420-B.H.P. double-acting compound engine for £1,375; also that of Messrs. Easton, Anderson & Goolden, for the supply of a 250-unit alternator for £1,075; that of Messrs. Rootham & Jeakings, for the erection of offices, store rooms, &c., near the electric light station, for £309. 100 electric lamp columns are to be obtained from Mr. W. Bradley, of Rastrick, for £250. A motor and flexible shafting for cleaning boiler tubes are to purchased at an estimated cost of £68.

Hull.—We understand that the Works Committee has given the contract for the electrical equipment of the tramways (including 20 cars) to Messrs. Siemens Bros. & Co. for £42,228.

Sheffield.—The Brush Electrical Engineering Company, Limited, has received an extension order from the Sheffield Electric Light and Power Company for a 600-kw. steam alternator for next winter's load, the plant to consist of an "Inductor" pattern alternator coupled direct to an "Universal" steam engine.

FORTHCOMING EVENTS.

1898.

Friday, February 4th, at 8 p.m.—The Institution of Junior Engineers, at the Westminster Palace Hotel. Paper on "Electro-Magnetic Brakes, and their Capabilities," by Mr. Louis H. Walter, A.I.E.E., of Cambridge.

At 12 noon.—Eastern Telegraph Company, extraordinary general meeting at Winchester House to confirm resolution approving the Company's Bill for capital conversion, &c.

Royal Institution. Mr. A. A. Campbell Swinton on "Some New Studies in Cathode and Röntgen Radiations."

Saturday, February 5th.—Institution of Electrical Engineers. Student's visit to the works of Messrs. Siemens & Co., Woolwich. Train from Fenchurch Street, 10.5 a.m. Applications to join the party, to the Student's Hon. Sec. (Mr. S. Grant, 28, St. Mary Abbot's Terrace, W.)

Monday, February 7th, at 7.30.—Society of Engineers' meeting at the Royal United Service Institution. Presentation of premiums by retiring president, Mr. G. M. Lawford. Presidential address, Mr. W. W. Beaumont.

Tuesday, February 8th.—Liverpool Overhead Railway Company. Meeting at Liverpool.

Ordinary and extraordinary general meetings of the St. James's and Pall Mall Electric Light Company.

Wednesday, February 9th, at 8 0 p.m.—The Institution of Electrical Engineers. "Notes on the Electro-chemical Treatment of Ores containing the Precious Metals," by Major-Gen. Webber, C.B., Past-President (conclusion of discussion). "An Electrolytic Process for the Manufacture of Parabolic Reflectors," by Sherard Cowper-Coles, Member.

At 12 o'clock.—City and Guilds Central Technical College, Exhibition Road. Second of a series of three lectures on "The Design and Testing of Power Cables for Specific Purposes," by Mr. Mervyn O'Gorman.

At 8 p.m.—Society of Arts. "Compensation to Workmen." By A. D. Provand, M.P.

Thursday, February 10th, and Friday, February 11th.—The annual general meeting of the Institution of Mechanical Engineers, at 25, Great George Street. The discussion on Mr. Philip Dawson's paper on "Mechanical Features of Electric Traction," will be resumed. A paper will be read and discussed as follows: "First Report to the Gas Engine Research Committee; Description of Apparatus and Methods, and Preliminary Results," by Prof. Frederic W. Burstall.

Friday, February 11th.—Physical Society (rooms of the Chemical Society, Burlington House). Annual General Meeting at 5 p.m.—Address by the President. After which at an Ordinary meeting: "On Electro-magnetic Induction in Plane, Cylindrical and Spherical Current Sheets, and its Representation by Moving Trails of Images," by G. H. Bryan, M.A., F.R.S.

NOTES.

Institution of Junior Engineers.—The 13th anniversary dinner of the members of this Institution was held at the Westminster Palace Hotel, Victoria Street, on Saturday night. Mr. J. A. F. Aspinall, M.Inst.C.E., the president, occupied the chair. Mr. Alexander Siemens proposed the toast of "British Railways," and Mr. R. Harrison, general manager L. & N. W. Ry., in response, congratulated Mr. Siemens and his fellow-workers on the Employers' Federation on the settlement of the engineers' dispute, which, he said, had been brought about after much labour and much anxiety. It was a settlement which, he thought, would be for the benefit not only of the employers—who did not even claim that it was a victory—but also of the workmen, and, not least of all, of the railway companies and those who had to transport the manufactured articles and the materials necessary for their manufacture. The chairman also responded. The toast of "A Realised Teaching University for London" was proposed by Dr. Perry, F.R.S., and Prof. Silvanus Thompson, F.R.S., in response, referred in eloquent and impassioned terms to the up-hill nature of the task in which the advocates of the reconstruction and enlargement of the University of London had been engaged. It was, he said, an extraordinary thing that in this great capital no opportunity should be offered for a student to take a degree in engineering. The apathy of London members of Parliament on the question was astonishing, seeing how great was the need for the reconstruction of the University. Mr. J. W. Swan, F.R.S., president of the Institution of Electrical Engineers, proposed the toast of the evening, "The Institution of Junior Engineers." He said the extension and greatness of the Empire were mainly due to the genius and enterprise of engineers, with whose future work the interests of the country were bound up. Mr. Vorley, who responded, mentioned that the Institution now comprised 500 members. Before resuming his seat he gave the toast of "The Honorary Members." Mr. Hiram S. Maxim, in reply, spoke of the advantages which electricity possessed over steam, and said it was to the former force that they must look if they wished to have more rapid transit and to double the speed attainable by the locomotive. The evening was a thoroughly enjoyable one; indeed, Mr. W. T. Dunn, the popular and indefatigable secretary, invariably makes the Institution dinner a success in every way, but on this occasion the speeches were specially good, the music, for several years past a feature at these annual gatherings, was highly appreciated, and the cinematographic display of the Queen's Diamond Jubilee procession was admirably handled by the Messrs. Prestwich. We shall hope to see in each succeeding year large accessions to the ranks of the Junior Engineers, for to them we look for the men to carry on the work begun by those, who, one day, must leave the younger members of the profession to bring it to finality. The Junior Engineers may rest assured that nothing will be wanting on the part of the technical press to encourage them in all ways, and to give publicity to the doings of such an important body, youthful though it may be. What it lacks in experience, it makes up for in energy and determination to make its power felt, and we shall always take a pleasure in doing all that lies in our power to foster the further development of the Institution.

Obituary.—The death of Lord Sackville Arthur Cecil took place on Saturday afternoon at Holwood, Beckenham, Kent, the seat of his mother, Mary, Countess of Derby. His lordship had been ill for some eight weeks, but was making progress towards recovery until an attack of pleurisy supervened on pneumonia, which, in his weakened state, he was not able to fight against. He was a son of the second Marquis of Salisbury, and was born in 1848. Educated at Wellington College and Trinity College, Cambridge, he took his B.A. degree in 1869 and his M.A. in 1872. He had considerable scientific attainments, and became very well known in connection with both railways and telegraphs. In 1869 he acted as chief electrician on board the cable steamer *Africa* during the laying of the Marseilles Bona and Malta cable, and in 1870 served on the staff of the late Sir Charles Bright supervising the manufacture of telegraph cable for the Panama and South Pacific Company. Both these cables are to-day in working order between France and Algeria, the destination of the latter having been changed on account of a law suit and the subsequent liquidation of the Panama and South Pacific Company. From 1878 to 1880 he was assistant general manager of the Great Eastern Railway, and from 1880 to 1885 he was general manager of the Metropolitan District Railway. He also became chairman of the Exchange Telegraph Company and director of the Eastern Telegraph Company, the Brazilian Submarine Telegraph Company, the Globe Telegraph and Trust Company, and the Pacific and European Telegraph Company. He was a man of great activity, and was possessed of an enormous capacity for work. Lord Sackville Cecil's rectitude of character won the esteem of all those who were thrown into contact with him, and his loss will be severely felt by his numerous friends, and by the companies with which he was connected. The deceased was one of the original members of the Institution of Electrical Engineers.

On Thursday, the 27th ult., Major Alexander Wood was buried in the Parish Churchyard of Erith, in which district he had lived for some 25 years. The deceased was well known in telegraph circles, through his connection with the Western and Brazilian Telegraph Company, which he piloted through many storms. The loss of his keen perception and his master mind will be deeply felt by his colleagues. To those who served under him will his loss be great, as Major Wood's generous disposition made him continually think of the absent toilers whose work, in sometimes unhealthy climates, contributes so much to the well being of their chiefs and employers at home. While a generous man, the deceased was far from being a weak one, as he dealt severely with things and men when the occasion demanded this treatment. Major Wood was born at sea in 1843, and was the son of Captain Wood, one of the band of pioneer explorers in Central Asia. In early life he belonged to the Bombay Staff Corps, and saw active service in China and Japan. On his retirement from the Indian Army, in 1872, he began the work of his life, and in various capacities was connected with the projected Great Western Telegraph Company, with the Western and Brazilian Telegraph Company, the late Central American Telegraph Company, the Platino-Brazilian Company, and the Amazon Telegraph Company. Until within a year of his death, when his health failed him, he was the active head of the Western and Brazilian, the Platino, and the Amazon Companies. He was also director of the Pacific and European Telegraph Company. Many of our foreign readers may remember the cheery, active personality who attended the International Telegraph Conference of London, Berlin, and Paris. We join with many others in tendering our sympathy to his bereaved family.

We regret to record the death of Mr. C. W. Stronge, C.B., who succumbed to pneumonia at his residence in Whitehall Court on Sunday last. Mr. Stronge was born in 1816, the third son of the late Sir James Mathew Stronge, Bart., of Tynam Abbey, Armagh, and entered the Treasury in 1833. After a service of half a century in that Department, he retired from the post of principal clerk. He had at different periods of his career acted as private secretary to different Ministers, among these the Earl of Derby, during his Premiership. Mr. Stronge was made a Companion of the Bath on the recommendation of Lord Beaconsfield. He had served as official Government Director on the boards of subsidised telegraph and steamship companies, and at the time of his demise, was a director of the Eastern, and of the Eastern and South African Telegraph Companies.

Puzzle—Find the Trolley.—We sometimes get interesting news from across the Atlantic as to what is being done on this side. Occasionally the information is known there sooner than here, and we wonder why it has not been first divulged in England. For a quite new and interesting piece of information we go to the *American Machinist*, which says:—

> On a trolley line in Birmingham, England, the rails are made in Pittsburg, the cars in Philadelphia, the boilers in Erie, the engines in Milwaukee, and the electric fittings in Schenectady.

This paragraph bears a very rosy complexion to the American electrical manufacturers' eyes, which would be quite justifiable if only it were true. What we should like to know is, "How long has there been a trolley line at Birmingham?" This is the first we have heard of it.

Electric Automobiles in France.—The Société des Voitures Electriques, using the Krieger system, the large and well-known Parisian carriage works, which was established in 1895, will probably soon be known by the title of Compagnie des Automobiles Electriques, it being now, says the Paris correspondent of the *Electrical World*, on the point of changing its organisation, and making its capital 5,000,000 francs ($1,000,000). According to some comparative calculations of all the costs of installation and operation required by animal, oil-motor, and electric traction, this company states that all the advantages of economy lie with the electric system. For daily cost of operating cabs they give:—

For animal traction	15.44 francs	($3.10)
For a petroleum automobile ...	13.20 „	($2.65)
For an electric automobile ...	8.13 „	($1.63)

Dust Destructors and Electric Lighting. — The glowing accounts which are given from time to time about the success of the Shoreditch combined plant are having their effect, and municipal authorities in various parts are pursuing inquiries into the subject, in the belief that success is already assured. The Johannesburg Town Council has decided to go in for dust destructors, and the suggestion is now being made there to erect them at the electricity station at the lower end of President Street. In this connection, *Machinery*, a South African paper, urging steps to be taken in this direction, cites the Shoreditch plant as an "unqualified success from all points of view," and well worth imitating. As to the "unqualified success," we will, without referring again to the question of fuel, simply draw attention to some of the points raised on this very interesting subject, by Mr. Robert Hammond, in his remarks to the Gloucester Town Council last week. A brief report appears in another column.

Personal.—Mr. A. E. Worswick, chief electrical engineer of the Cape Town Tramways Company, has left Cape Town for Mexico, to take up a position in connection with the administration of a large electric traction system.

Forthcoming Lectures.—A special course of lectures on "The Design and Testing of Power Cables for Specific Purposes," have been arranged by the City and Guilds Institute to be delivered at the Central Technical College on Wednesdays at 12 o'clock, by Mr. Mervyn O'Gorman, late manager of the Fowler-Waring Cables Company. The first lecture was given on Wednesday, 2nd inst., and the others will take place on 9th and 16th inst.

Professorship Vacant.—Prof. Carey Foster resigns the Quain Professorship of Physics at the University College, London, at the close of the present session. Applications for the chair have to be made to the secretary, Mr. J. M. Horsburgh, M.A., by March 1st.

Our Volunteers.—A daily paper says that it is intended by the War Office to appoint non-commissioned officers of the Royal Engineers for the permanent staff of the new Corps of Electrical Engineer Volunteers, as soon as their services are required for training the Corps.

Toy Science.—This month's issue of *Good Words* has a very interesting illustrated article by Mr. James Swinburne on "Science of Some Toys."

Appointments Vacant.—The Birkenhead Corporation want a resident electrical engineer, at £300 per annum. See our "Official Notices."

The Northwich Electric Supply Company want a resident electrical engineer for their gas-driven electric light works. See our "Official Notices."

Municipal Electrical Association.—We hear that Mr. Alfred H. Gibbings, the city electrical engineer of Bradford, has been elected president of the Municipal Electrical Association, in succession to Mr. C. H. Wordingham, and will preside at the annual covention in London next June.

Lectures on "Electro-Deposition."—Prof. S. P. Thompson commenced on Wednesday at the Finsbury Technical College, a course of laboratory instruction and lectures on "Electro-Deposition." A syllabus of the course has been issued.

Falcon Works Engineering Society.—A very successful meeting of the Falcon Works Engineering Society was held at Loughborough, on Thursday last. Mr. R. P. Sellon presided, and a most interesting paper was read by Mr. J. J. Steinitz, the Borough electrical engineer for West Ham, on "Some Practical Hints on Starting a Municipal Electrical Department."

The American Blizzard.—The American blizzard has played havoc with the telegraph, telephone and trolley wires in Boston. The wires are down in all directions, and some of the accounts in the press say that over 200 horses lie dead in the streets through electrical shocks and extreme cold.

Lectures.—On the 22nd ult., Mr. A. H. Fison, D.Sc., commenced a series of ten lectures on "The Electric Current and its Modern Applications," at the Technical Institute, Wandsworth.

At the Bishopsgate Ward Club, last week, Mr. W. C. C. Hawtayne read a paper on "The Supply of the Electricity from Central Stations," and dealt with the question of municipal *v.* private enterprise. He referred to the error committed by the Commission of Sewers in giving over its electric lighting powers to two companies.

Mr. F. H. Headley read a paper on "Electricity, the Transmitter of Power," before the Mining Association and Institute of Cornwall, on Wednesday last week.

Mr. Wm. Lynd is delivering a series of lectures on "Wireless Telegraphy," in the Free Trade Hall, Manchester.

Presentation to Mr. H. C. Fischer, C.M.G.—It is stated that a movement is on foot among the superintendents and staff of the Central Telegraph Office, for the purpose of making farewell presentations to Mr. H. C. Fischer, C.M.G., who is, as already stated, about to relinquish the office of comptroller.

Personal.—Mr. Mervyn O'Gorman, late of the Fowler-Waring Cables Company, has joined Mr. E. H. Cozens-Hardy, chief assistant to the Brush Company's engineer, in an examination of Continental and American methods, with a view to a subsequent partnership in consulting work.

Telegraph Directors Dead.—The Pacific and European Telegraph Company has, within the last week, lost two members of the Board, in the persons of Lord Sackville Cecil and Major Alexander Wood. In addition to these two names a third has to be registered, Mr. C. W. Stronge, C.B., a director of the Eastern Telegraph Company, who has also died in the same week.

Telegraphists' Grievances.—The Postal Telegraph Clerks' Association have drawn up a circular letter which each postal employé will forward to the member for the constituency in which he lives, urging him to be present at the House of Commons on February 8th, when Mr. Sam Woods is to lay before Parliament the grievances of the service. The circular, says last night's *Pall Mall*, calls attention to the alleged inadequacy of pay and insufficient prospects, and points out that a man must complete 21 years of irreproachable service before he can receive 56s. per week. The association ask for a prospective £200 after 25 years of service, claim the absolute right of combination and free speech, and particularly call attention to the fact that absence through sickness for nine days may lead to compulsory retirement. They desire that this rule should be cancelled.

NEW COMPANIES REGISTERED.

Clench & Co., Limited (55,749).—Registered January 21st, with capital £80,000, in £10 shares, to acquire the business of "Clench & Co.," of Lincoln Works, Chesterfield, and elsewhere, to adopt an agreement with F. and G. M. Clench, and to carry on the business of mining, electrical, mechanical and general engineers, tool and implement makers, boiler makers, metal workers, &c. The subscribers (with one share each) are:—F. Clench, Lincoln Works, Chesterfield, engineer; G. M. Clench, Lincoln Works, Chesterfield, engineer; H. S. Johnstone, Springfield Road, St. Leonard's-on-Sea, solicitor; S. G. McDakin, 15, Esplanade, Dover, retired captain; E. Clements, 74, Southgate, Sleaford, engineer; E. W. Whattan, Rutland Road, Chesterfield, clerk; D. H. Davis, Longlands, Chesterfield, solicitor. The number of directors is not to be less than three, nor more than five; the first are the first five subscribers. Qualification, £500; remuneration as the company may decide. Registered by Devonshire & Co., 1, Frederick's Place, Old Jury, E.C.

Trehearne Electrical Engineering Company, Limited (55,798).—Registered January 26th with capital £2,000 in £1 shares, to carry on the business of electrical engineers, suppliers of electricity, electricians, electrical apparatus manufacturers, &c. The subscribers (with one share each) are:—S. G. Trehearne, 155, Fenchurch Street, E.C., electrician; J. A. England, 118, Abbeville Road, Clapham, stationer; A. J. Jackson, 66, Heaton Road, Peckham, gentleman; R. Bridge, Innellan, Cavendish Road, Sutton, printer; W. H. Hughes, 155, Fenchurch Street, E.C., clerk; F. C. Powell, 248, Haydon's Road, South Wimbledon, clerk; H. C. Clarke, Oakleigh, Merton Hall Road, Wimbledon, assistant. Table "A" mainly applies. Registered by S. G. Trehearne, 155, Fenchurch Street, E.C.

W. J. Jenkins & Co., Limited (55,826).—Registered January 27th, with capital £20,000 in £10 shares, to acquire the business carried on as "W. J. Jenkins & Co.," at the Beehive Works, East Retford, Notts., to adopt an agreement with W. J. Jenkins, and to carry on the business of gas, electrical and mechanical engineers, iron founders, millwrights, metal workers, contractors, &c. The subscribers (with one share each) are:—L. F. Trafford, 2, Sloane Street, S.W., major; Mrs. A. R. Trafford, 7, Sloane Street, S.W.; G. R. Trafford, Oxford and Cambridge Club, S.W., gentleman; J. Goodman, Yorkshire College, Leeds, professor; C. P. Smith, 41, St. Michael's Road, Northampton, traveller; J. W. Durnford, 24, Caledonian Road, East Retford, engineer; W. J. Jenkins, 125, Thrapston Road, East Retford, engineer. The number of directors is not to be less than three nor more than five; the first are:—L. F. Trafford, J. Goodman and W. J. Jenkins; qualification £1,000; remuneration as fixed by the company. W. J. Jenkins is the managing director with £400 per annum. Registered by Jordan & Sons, Limited, 120, Chancery Lane, W.C. Registered Office, Beehive Works, Retford, Notts.

Langdon Davies Electric Motor Company, Limited (55,830).—Registered January 27th, with capital £70,000 in £1 shares, to adopt an agreement with the Davies Motor Company, Limited, for the acquisition of certain agreements relative to alternate current motors, and to carry on the business of electricians, engineers, light and power contractors, and electrical manufacturers. The subscribers (with one share each) are:—E. W. S. Crawley, 44, Castletown Road, West Kensington, engineer; C. E. Cree, 12, Nevern Road, Earl's Court, barrister; A. W. Cree, Brodsworth, Beckenham, solicitor; H. E. Cree, Benenden, Eastbourne, solicitor; W. S. Matingly, 113, Highbury Hill, N., clerk; W. L. Davies, 61, Gwendwr Road, West Kensington, engineer; A. Soames, Walpole Lodge, Bromley, Kent, engineer. The number of directors is not to be less than three nor more than nine. The first are C. E. Cree, A. W. Cree, W. Langdon Davies, A. Soames, and E. W. S. Crawley. Qualification £1,000; remuneration not more than either 10 per cent. of the profits, or a £1,000 per annum dividend. Registered by Cree & Son, 13, Gray's Inn Square, W.C.

United Ordnance and Engineering Company, Limited (55,860).—Registered January 29th with capital £550,000, in £1 shares (275,000 £5½ per cent. cumulative preference), to acquire and turn to account the benefit of a contract with Schneider & Co., of Creuzot, for the manufacture of the Schneider-Canet Artillery, in the United Kingdom and its colonies, to acquire and carry on the business of mechanical, hydraulic, electrical and mining engineers, carried on by Easton, Anderson & Goolden, Limited (registered in 1894), and to adopt an agreement with E. T. Hooley. The subscribers (with one share each) are:—H. F. Nicholson, Cobham, Kent, admiral; C. Cammell, Sheffield, gentleman; H. K. Baynes, 15, Chapel Street, S.W., gentleman; W. T. Marriott, 56, Ennismore Gardens, S.W., Queen's councillor; E. Legge, 7, Albion Street, W., barrister; P. B. Dobson, Zulla Road, Nottingham, gentleman: H. P. King, 36, Savernake Road, South Hampstead, clerk. The number of directors is not to be less than five nor more than eleven; the first are—H. F. Nicholson, K.C.B., F. Elgar, H. McCalmont, E. Cammell, P. Mosley, T. Wilson, and H. K. Baynes. Qualification £1,000; remuneration £300 each per annum (£500 for the chairman), together with £1,000 per annum, divisible, for every 1 per cent. in the ordinary dividend above 5 per cent. Registered by Golding & Hargrove, 93, Cannon Street, E.C.

OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

Railways' Electric Supply Syndicate, Limited (52,812).—This company's statutory return was filed on November 13th, when 7,000 shares were taken up and issued as paid, out of a capital of £10,000 in £1 shares.

Silicon Electric Lamp Syndicate, Limited (47,238).—This company will not be proceeded with, as the patents, for the acquisition of which the undertaking was formed, have been otherwise disposed of and the name of the company will be struck off the register.

Rand Central Electric Works, Limited (43,712).—This company's annual return was filed on January 7th, when the capital of £300,000 in £1 shares was taken up in full. 25,000 shares are considered as paid, and £275,000 has been received.

Single-Wire Multiple Telephone Signal Company, Limited (16,875).—This company's annual return was filed on December 24th, when 374 shares were taken up and paid for in full, out of a capital of £5,000 in £10 shares.

CITY NOTES.

The St. James' and Pall Mall Electric Light Company, Limited.

The ordinary general meeting will be held at Carnaby Street Central Station, Golden Square, W., on Tuesday, February 8th, at 12 o'clock, and the directors' report to be then presented reads as follows:—"The directors submit their report for 1897, with the accounts as certified by the company's auditors. The extension of Carnaby Street Station is on the point of completion, and will soon be equipped with a full plant of 5,000 horse-power. It has been working satisfactorily throughout the year in connection with the station at Mason's Yard. Steady progress has been made in the increase of the company's supply to private consumers, and the principal streets of the district are now lighted by electricity. An agreement, dated December 16th, 1897, has been made with the holders of founders' shares by which, subject to confirmation by the shareholders, they will receive an allotment of 120 ordinary shares at par in exchange for each founders' share, such exchange to take effect as and from January 1st, 1898. In order to carry out this agreement steps are being taken to increase the capital of the company to £300,000 by the creation of 20,000 new ordinary shares of £5 each, of which 12,000 £5 shares are to be issued at par to the holders of the founders' shares. This will give the company £60,000 additional capital at once, and will, in effect, extinguish the founders' shares. The net earnings of the company during the past year have amounted to £29,093 17s. 7d. Of this sum, £6,996 10s. was distributed in August last in payment of an interim dividend at the rate of 7 per cent. per annum for the half-year ending June 30th, 1897, on the ordinary shares, and of 7 per cent. per annum on the preference shares. The balance, £22,097 7s. 7d., together with the undivided profit of £327 15s. 9d. from last year's account, leaves £22,425 3s. 4d. now to be dealt with.

"The directors propose to divide the amount as follows:—

	£	s.	d.
(a) By payment of a dividend at the rate of 7 per cent. per annum on the preference shares for the second half of the year	3,500	0	0
(b) By payment of a dividend on the ordinary shares for the second half-year of 11s. per share, making, with the interim dividend paid on August 2nd last, a total distribution of 14½ per cent. for the year	10,989	0	0
(c) By payment of a dividend of £75 10s. 4d. per share on the founders' shares...	7,551	13	4
(d) Amount to be carried forward to ordinary shareholders' undivided profit account ...	384	10	0
	£22,425	3	4

"Sir John H. Morris, K.C.S.I., and Mr. Bennett Fitch, M.Inst.C.E., are the directors who retire by rotation under clause 79 of the articles of association, and, being eligible, offer themselves for re-election. The auditors, Messrs. Deloitte, Dever, Griffiths & Co., also retire, and, being eligible, offer themselves for re-election."

At the conclusion of the annual ordinary meeting of the company, an extraordinary general meeting will be held for the purpose of confirming the following resolutions passed at the extraordinary general meeting of the company, held on January 18th, 1898, so as to make them special resolutions:—

"1. That the agreement bearing date December 16th, 1897, and made between the company of the first part, the parties whose names are subscribed in the first column of the schedule thereto, being the registered holders of the 100 founders' shares of £1 each in the company of the second part, and Eustace James Anthony Balfour and Josiah Latimer Clark of the third part, be, and the same is hereby approved, and that the directors be, and they are hereby authorised to carry the same into effect.

"2. That the capital of the company be increased to £300,000 by the creation of 20,000 new ordinary shares of £5 each, and that notwithstanding the provisions of article 4 of the articles of association, 12,000 of such 20,000 new ordinary shares of £5 each be issued at par to the registered holders of the 100 founders' shares of £1 each in the company as provided by the said agreement, December 16th, 1897.

"3. That the directors be and they are hereby authorised to issue to any registered holder of a founders' share at any time hereafter, not more than 120 new ordinary shares of £5 each at par upon such founders' shareholder transferring each founders' share, of which he is the registered holder to Eustace James Anthony Balfour and Josiah Latimer Clark as trustees for the company, nothwithstanding that the said agreement of December 16th, 1897, may not have been executed by the holders of the whole of the said 100 founders' shares within the three months provided by Clause 5 thereof."

City and South London Railway Company.

The ordinary general meeting was held last Friday at Winchester House, Mr. Charles G. Mott presiding. In moving the adoption of the report, the chairman regretted that they were not able to recommend an increase in the dividend on that occasion over what they paid for the corresponding period of the previous year. In the December half of 1896 they had what was for them a very large increase in their traffic owing to two very important matches of the Australian cricketers at the Oval, and, moreover, that half-year was favourable for them, the weather having been severe as compared with the mild and dry autumn or early winter they had had this year. It was, he thought, very satisfactory that they were able to show, in the circumstances, an increase in their receipts from passengers and parcels of about £40. He thought it clear that a natural increase was going on in their traffic, apart from what they might derive from exceptional causes. Their line at present had no connections with any other railways, nor did it run through a district which was a very busy one. The extensions were going on very satisfactorily, and considerable progress had been made at Finsbury Pavement. Both tunnels were very nearly completed along Moorgate Street to the Bank. It would take some weeks before one of these tunnels was quite finished up to the Bank, and they would then only have to tunnel a very little further up to the station in Lombard Street. The tunnel on the south side of the river, starting at Denman Street for the London Bridge Station, and going in a southerly direction, was very nearly completed, and would in a few weeks be up to the junction with the old line, where the new line left the existing line. One of the tunnels from that station northwards towards the City was completed to the extent of about one-third under the river. The necessity which they were under of upholding the church of St. Mary Woolnoth, at the corner of Lombard Street, which had given them a great deal of trouble in the past, would probably cause them some delay. In view of this fact and the necessity which had been thrown upon them of upholding the church, they were asking Parliament in a Bill they were promoting this Session to empower them, if there was any consequent delay in completing the line within the time expected, and they therefore had to incur expenditure in dividend on the preference shares they had issued, to charge such dividend in the first instance to capital account. As they were aware, they issued for these extensions £200,000 of preference shares, the dividend on which was deferred, and was not to begin to accrue until January 1st next. The first half-yearly dividend on these shares would not become payable until August, 1899, and he might state that the reserves they now had in hand were equal to one-half of the dividend which they would then have to pay. They had been acquiring property for the station for the Clapham extension, as they thought it very desirable that that line should, if possible, be completed by the time that the other extensions were finished and opened. Most of the property necessary for the two stations in connection with that extension had been acquired. They were negotiating for letting the contract for this extension, in connection with which they were, of course, providing for increased power, &c., at the generating station. The contract time for completing this extension would expire on September 30th next, and they had good hopes for believing that a year hence they might be able to announce that that line was ready for opening. Having referred to the City and Brixton Railway, and to the negotiations which had gone on with certain parties who were willing to construct this line, he stated that their company would work it from their central generating station. They would hold a Wharncliffe meeting on the 17th prox., when they would submit that company's Bill and also their own Bill, when full details would be given and the provisional arrangement with the City and Brixton Company would be set forth. With a view to an interchange of traffic they had entered into an arrangement with the Central London Railway Company, whose line commenced at the Mansion House and went by way of Holborn and Oxford Street to Shepherd's Bush. That company, he believed, would have a very important traffic, and it had been arranged that the platforms of their stations at the Bank and their station below should be connected by a short subway. They believed there would be a very large interchange of traffic in consequence of this arrangement, which would prove of great convenience to a vast number of people. Their Finsbury Pavement station was exactly opposite the booking office of the Moorgate Street station, and there should be a considerable interchange of traffic between the two lines. They would also have an interchange of traffic at London Bridge with the South-Eastern and Brighton companies. When, too, the Clapham extension was completed, they would have a station very near the Clapham Road station of the Chatham and Dover Company, and there also there would be a means of interchange of traffic. In addition, powers had already been obtained for two other lines, which were going to Finsbury Pavement—he referred to the Great Northern and City Railway, which would go from Finsbury Park to Finsbury Pavement, and the Epping Forest and Walthamstow line, the terminus of which would be very close to Finsbury Pavement station. Traffic would be brought to their undertaking by these lines from all parts of London, and an immense interchange of traffic might be looked for with these different railways. They had deposited a Bill for extending the time for constructing that part of the line which it was not at present proposed to build—namely, from Finsbury Pavement to the Angel at Islington.

Mr. Sampson Hanbury seconded the motion, which was adopted.

Buenos Ayres and Belgrano Tramways Company.

An extraordinary general meeting of this company was held on Tuesday, at Winchester House, for the purpose of considering a draft agreement with the Buenos Ayres and Belgrano Electric Tramways Company, Limited, for amalgamation with the latter.

Mr. John Morris, who presided, said the proposed new company would have a larger mileage of lines than the present one, and for horse traction it was intended to substitute electricity. The advantages of electric traction had long been before the public in other countries to a greater extent than in England. In the United States it had almost everywhere superseded animal power, and on the Continent of Europe, especially in Germany, it was well known and highly appreciated both on account of its convenience and economy. With electric traction it was possible to estimate accurately the cost of running cars, as it made companies independent of good or bad harvests, and other temporary causes of that kind. The cost of traction was practically reduced by one-half. He quoted the experiences of Montreal and Hamburg, in both of which the old tramways had fallen upon evil days, but had been resuscitated and made prosperous by the adoption of electricity.

The proposal was carried.

Official Announcements re Companies.

The Registrar of Joint Stock Companies gives notice in the *London Gazette* that the following and many other companies will be struck off the register within three months, unless cause is shown to the contrary:—

Birmingham House-to-House Electricity Company, Limited.
Caustic Soda and Chlorine Syndicate.
Dalziel's Atlantic Telegram Company.
Electrical Accessories Company.
Electric Light and Power Share Trust.
Exeter Electric Light Company.
Irish House-to-House Electricity Company.
Lancashire and Cheshire House-to-House Electricity Company.
Liverpool House-to-House Electricity Company.
Manchester House-to-House Electricity Company.
Midland House-to-House Electricity Company.
Nightingale Automatic Electrical Machine Company.
Northern House-to-House Electricity Company.
Pacific Telegraph Company.
Railway Electric Fog Signal Syndicate.
Railway Electric Reading Lamp Company.
South of England House-to-House Electricity Company.
Western House-to-House Electricity Company.
Wrexham and District Electric Supply Company.

Metropolitan Electric Supply Company.

The following letter from a holder of founders' shares in this company appears in the *Financial News*:—"The proposal of the directors of the Metropolitan Electric Supply Company to offer in exchange for each founders' share an allotment of 140 ordinary shares at par, strikes me (a holder of two of the founders' shares) as a very inadequate proposal considering the present rapidly-increasing revenue of the company. It must be remembered that there are only 100 founders' shares in this company, and that the holders thereof are entitled to one-half of the entire profits after 7 per cent. is paid on the ordinary; this will ultimately mean a very large sum indeed as the capital increases. I venture to think, therefore, that the holders of founders' shares will do well to decline the directors' proposal at the forthcoming meeting.—C. Temple Layton."

Anglo-American Telegraph Company, Limited.

The report of the directors to the ordinary general meeting of the proprietors, to be held at Winchester House to-day, at 2 o'clock p.m., states that the total receipts from July 1st to December 31st, 1897, including the balance of £8,507 5s. 11d. brought forward from the last account, amounted to £187,832 0s. 11d. The traffic receipts show an increase of £6,540 as compared with the half-year ended December 31st, 1896. The total expenses of the half-year, including the repair of cables, &c., as shown by the revenue account, amounted to £58,372 4s. 5d., being an increase of £371 16s. 8d. over the corresponding period of 1896. The directors, under the powers conferred upon them by the articles of association, have, before declaring the net profits, set apart the sum of £12,000 to the renewal fund, leaving a balance of £117,459 16s. 6d. Interim quarterly dividends of 14s. per cent. on the ordinary stock, and £1 8s. per cent. on the preferred stock, were paid on November 1st last, absorbing £49,000, leaving a balance of £68,459 16s. 6d., out of which the directors recommend the proprietors to declare final dividends of 19s. 6d. per cent. on the ordinary stock, and £1 19s. per cent. on the preferred stock, amounting to £68,250, thus making a total distribution for the year ended December 31st, 1897, of £3 per cent. on the ordinary stock, and £6 per cent. on the preferred stock. The balance of £209 16s. 6d. will be carried forward to the next account. The cables and land lines of the company are in good working order. In accordance with the articles of association, two directors of the company, Sir Gerald FitzGerald and Charles Burt, Esq., retire at this meeting, and, being eligible, offer themselves for re-election. Mr. Joshua Dean and Mr. John Gane, F.C.A., the auditors, retire, and offer themselves for re-election.

Central London Railway Company.

The fifth ordinary general meeting was held on Wednesday at 16, Great George Street, S.W., Mr. Henry Tennant presiding.

The Chairman remarked that the number of shareholders had slightly increased during the half-year, and the number now stood at 1,073. In moving the adoption of the report, he said: On reference to the report you will perceive that the expenditure up to the end of the half-year now under review, has been £1,606,948 7s., and that the amount received on shares is £1,407,042. The expenditure, therefore, appears to have been more than the receipts, and the capital account shows a debit balance of £199,906 7s. Now this, in the main, is explained by the fact that £228,000 odd appears as owing to the Electric Traction Company under certificates from the engineers—that is, the engineers have certified that this sum is due to the contractors, and the company have not paid them. If you will look at the accounts, you will see that the Traction Company covenanted to take up a certain number of shares, and they now stand in the accounts as unissued shares. This, the Traction Company are ready to do, and therefore the sum entered as payable to them will be disposed of on the transactions as to the shares being completed, and that will be so completed before very long. The share capital, when that has been done, will stand thus:—The whole of the share capital will stand as issued with no less than £6 per share paid up thereon. I think there is nothing else in the accounts which I need trouble you about at present. What is more important is the question of the progress of the works which is dealt with in the engineers' report. According to that report, good progress has been made during the past six months, and I am glad to say that no serious hindrance to the engineers' operations have occurred during the half-year. You will observe the interesting fact that three-fourths of the ordinary tunnel—that is the main line tunnel, has been completed as well as one-half of the station tunnels—these station tunnels are, of course, a good deal wider than the ordinary tunnels so as to make room for platforms. One-half of these have been completed, and the shafts for the lifts, and staircases, the engineers say in their report, have been constructed. Of course, there may be some finishing work, but the main operation has been completed. I think I have said before that a very difficult work had to be undertaken, viz., the diversion of sewers. They are very difficult things to touch, especially in London, I think, and then gas and water pipes had to be taken up or removed, and all that had to be done under the pavement at the Bank Station. Now, this is proceeding satisfactorily, and part of it is practically complete, and the public subways are well advanced. The operations in connection with access from the Waterloo and City Company to the public subways at the Bank are also, according to the engineers, making satisfactory progress, although great difficulty was encountered in the construction of this part of the work owing to sewers and other obstructions which had to be dealt with. I hope that all these difficulties are now practically surmounted. We have agreed provisionally for the construction of a low level connection between the platforms of the City and

South London Railway and the platforms of the Central London at the Bank station. The terms are to be embodied in an agreement, which the South London Company are preparing, and as we have not yet received it, I am not in a position to say anything further at the present moment respecting it. The arrangements for the supply of electrical equipment have been made, and the works have been commenced. In the present position of the railway, there are no materials for any long speeches. The time will come when the occupant of the chair, whoever he may be, will have plenty to talk about—that is, when the line has been completed for traffic, and is earning a dividend. He moved the adoption of the report, and the payment of interest at the rate of 3 per cent. per annum on the paid-up capital of the company.

Lord Colville of Culross seconded the motion, which was agreed to.

Mr. Tennant was re-elected a director.

The Liverpool Overhead Railway Company.

The directors' report to be presented to the half-yearly meeting of the shareholders, to be held at the Law Association Rooms, 14, Cook Street, Liverpool, on Tuesday, 8th inst., reads as follows:—

"In presenting the half-yearly statement of capital and revenue accounts to December 31st, 1897, the directors have to report that the gross revenue receipts amount to £37,583, and the working expenses to £24,240 4s. 1d.

"The number of passengers carried during the last two years is as follows:—

	Half-year ending June 30th, 1896.	Half-year ending December 31st, 1896.	Half-year ending June 30th, 1897.	Half-year ending December 31st, 1897.

leaving a balance of £2,878 1s. 11d. to be carried forward to next half-year.

"The directors retiring by rotation at this meeting are Mr. Edward Lawrence and Mr. George Hunter Robertson, who, being eligible, offer themselves for re-election. The auditor retiring by rotation is Mr. George Nicholson, who is also eligible for re-election."

The Yorkshire House-to-House Electricity Company, Limited.

The annual general meeting of the shareholders of the Yorkshire House-to-House Electricity Company, Limited, was held on Tuesday afternoon at the Great Northern Hotel, Leeds, Mr. Grosvenor Talbot presiding.

The Chairman, in moving the adoption of the balance-sheet and report, said that he hoped it would prove satisfactory to all. The amount of capital now raised by shares was £131,932, an increase of £33,372 over last year. The total amount expended on capital account was £161,009, representing an increase of £55,632. The large additional expenditure had been due in the first place to the erection of new buildings. They had added 1,000 horse-power to their engine capacity, the total capacity being now 2,800 horse-power, and had also largely improved the means of supplying the current to the centre of the town. They proposed to pay the same dividend as last year, and for this half-year at the rate of 7 per cent., making 6 per cent. for the year. The depreciation fund now amounted to £6,660, and the reserve fund to £8,000, while the total amount they held in reserve in one form and another was £17,929. During the past year they had increased the number of lamps by 9,754, and the units sold by 131,871. The Chairman then referred to the recent reduction of price, which, he said, had made electricity in Leeds the cheapest illuminant, and then went on to deal with the proposed acquisition of the company by the Corporation. In connection with this matter, he said that the directors knew no more about the subject than the shareholders themselves. He felt sure that they would endeavour to meet the demand in a fair spirit. The Corporation were sending a deputation to meet the directors in a week's time. The company was a flourishing and progressive concern, and he was confident that whatever they would be able to get from the Corporation would not be anything like its value either in the property or the rights which the Corporation would gain and which they would have to surrender.

Mr. A. G. Lupton seconded the resolution, which was carried unanimously.

A number of questions were asked as to the suggested taking over by the Corporation. Mr. Colbeck said that he had heard that some of the founders' shares might come into the market in order that their position might be tested.

The Chairman said that he had not heard of there being any likelihood of anything of the sort taking place. He did not think that anyone really knew what the value of those shares was, though a gentleman had written from London offering £170 each for them. Not a single share of that class had ever changed hands.

In answer to a question as to whether an effort had ever been made to redeem the founders' shares, the chairman said that the directors had inquired into the matter, and discovered that they could not redeem the shares without putting such a burden upon the concern as to render it extremely improbable that the shareholders would consent to the scheme. It would be such an exhaustive process that it would do away with dividends for some time to come.

Mr. A. G. Lupton and Mr. J. T. Pearson were re-elected directors, and the meeting closed with a vote of thanks to the chairman.

National Telephone Company.—The directors last week resolved, subject to final audit, to recommend, at the forthcoming general meeting of shareholders, the following dividends for the half-year ending December 31st, last: At the rate of 6 per cent. per annum, less income-tax, on the amounts paid up on the first and second preference shares; at the rate of 5 per cent. per annum, less income-tax, on the amounts paid up on the third preference shares; at the rate of 6 per cent. per annum, free of income-tax, on the amounts paid up on the ordinary shares, carrying £40,000 to reserve, and about £9,000 forward. The transfer books will be closed from February 4th to the 17th, both days inclusive, and the dividend warrants will be posted on the latter date. With regard to the 130,766 third preference shares issued in June last, the dividends thereon will be calculated from the dates fixed for payment of the various instalments.

Stock Exchange Notices.—The Stock Exchange Committee has appointed Wednesday, February 9th, a special settling day in New General Traction Company, Limited—20,000 6 per cent. cumulative preference shares of £5 each, fully paid, Nos. 34,001 to 54,000; and has ordered the undermentioned securities to be quoted in the Official List: City and South London Company—further issue of 832 5 per cent. perpetual preference shares, Nos. 8,420 to 9,251; New General Traction Company, Limited—20,000 6 per cent. cumulative preference shares, Nos. 34,001 to 54,000.

General Electrolytic Parent Company.—The directors of the General Electrolytic Parent Company, Farnworth, near Widnes (owners of the Hargreaves-Bird Electrolytic Alkali process), have issued warrants to the shareholders for the payment of an interim dividend of 50 per cent. on the capital of the company, free of income-tax.

Waterloo and City Railway Company.—The report of the directors and statement of accounts for the half-year ended December 31st, 1897, states that the sum of £113,170 was expended during the half-year. The shares being now fully paid up, the directors recommend that they be converted into a general capital stock.

Cuba Submarine Telegraph Company.—The directors have declared a dividend for the past half-year at the rate of 6 per cent. per annum.

The Electric Light Company.—A private meeting of the above (a new company) was held on Monday last, at Cannon Street Hotel.

London Electrical Cab Company.—The letters of allotment for the new issue of shares, have been posted.

TRAFFIC RECEIPTS.

The City and South London Railway Company. The receipts for the week ending January 30th, 1898, were £1,059; week ending January 31st, 1897, £1,101; decrease £42; total receipts for half-year, 1898, £5,393; corresponding period, 1897, £5,488; decrease, £95.

The Liverpool Overhead Railway Company. The receipts for the week ending January 30th, 1898, amounted to £1,337; corresponding week last year, £1,227; increase, £110.

The Western and Brazilian Telegraph Company, Limited. The receipts for the week ending January 28th, 1898, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £2,808.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

ABSTRACT OF INAUGURAL ADDRESS.

By J. W. Swan, F.R.S., President.

(*Concluded from page* 132.)

Gold Extraction.

Before the introduction of the cyanide process for the treatment of gold ore, various electrolytic methods, chiefly based upon the solvent action of electrolytic *chlorine*, had been proposed and worked; but the purely chemical cyanide process has largely, if not wholly, superseded these electrolytic methods for the primary treatment of gold ore. Messrs. Siemens & Halske, however, have patented and successfully introduced a method for treating the cyanide liquors from the tailings, or waste sludges, produced in cyanide gold extraction, and containing a very small amount of gold. An extremely dilute solution of cyanide is employed to dissolve the gold. This is afterwards subjected to electrolysis, with iron anodes and thin lead cathodes, with a current density of one or two-tenths of an ampere per square foot. This results in an almost complete recovery of the gold in an adherent form upon the lead cathode. When the required amount of gold has been deposited, the cathodes are removed, and the gold separated by cupellation. This process appears to be exactly suited to the clean quartzite ore of the Transvaal. Over 1,000,000 tons a year of tailings, such as were formerly discarded as useless, are now profitable treated by this process.

Zinc Extraction.

The extraction of zinc from its ores by electrolysis is a problem, on the solution of which much ingenuity and a considerable amount of money have been expended. It is a tempting problem, inasmuch as the method in common use of reducing the native sulphide or the carbonate of zinc to the state of oxide by calcination, mixing this with non-bituminous coal, and distilling in clay retorts at an extremely high temperature, is absolutely barbaric in its primitiveness and its wastefulness.

A step has been recently taken towards this object by means of a process (the invention of Dr. Hoepfner) at present being worked by Messrs. Brunner & Mond. In this process zinc chloride is electrolysed; the products are chlorine and zinc. Such zinc is purer than ordinary commercial zinc, and will no doubt be welcomed by the users of zinc in primary batteries.

For the electrolytic treatment of that hitherto intractable class of ore such as the Broken Hill Mine produces—the mixed sulphides of lead and zinc—two processes deserve mention—one, the Ashcroft process, because very extensive preparations have been made for carrying it out on a large scale; and the other, that of Cowper-Coles.

These bold attempts in new directions deserve success.

Aluminium Extraction.

One of the largest, the most important, and in many respects the most interesting of the electro-chemical industries is that of the production of aluminium. In 1855 the price of aluminium was not far from the price of *silver*, when silver was twice its present value. Now, bulk for bulk, it is the price of *copper*. It is no longer bought by the *ounce*, but by the *pound* or *ton*. The full measure of change has been brought about by the employment of electrolytic extraction. It is an instance of an electrolytic method displacing a thoroughly elaborated and established chemical method, and of the enormous increase in demand that has followed a reduction of price. The production at the present time is, I estimate, not less than 2,000 tons a year. At least 10,000 horse-power is absorbed in this industry alone, and power to double that amount is about to be applied to it. There is every probability that new uses will be found for the metal, and that the manufacture will become a much larger one than it is at present.

Although English enterprise was prompt to adopt and improve the original chemical process, the production of aluminium had wholly departed from us until the British Aluminium Company recommenced the manufacture in the electrolytic form, across the Border, attracted there by the advantage of cheap water power.

The process by which aluminium is extracted, in *America*, on the *Continent*, and in *Scotland* to-day, is in principle exactly similar to that by which Davy extracted potassium from potash 92 *years ago*. The electrolyte is kept in a state of fusion by the electrically generated heat. There are nominally two processes in use, but the difference is extremely small—chiefly a slight difference in the composition of the electrolyte. That known as Hall's process has as its distinctive feature an electrolytic bath composed of potassium fluoride in which alumina prepared from bauxite is continuously dissolved; while in

Heroult's process the solvent of the alumina consists of cryolite, the double fluoride of aluminium and sodium. The electrolytic furnace consists of a carbon-lined iron box connected with the negative pole of a dynamo; this contains the electrolytic bath. Massive blocks of carbon are connected with the other terminal of the dynamo, and form the positive pole. These are immersed in the bath of fused material, and nearly reach the bottom.

The carbon used in the manufacture of the anodes and for lining the furnace is required to be of great purity and hardness. The current density employed is very large—about 700 amperes per square foot of cathode surface, about 8,000 amperes per cell. A difference of potential of 5 volts is maintained between the electrodes. In practice, 14 electrical horse-power hours are expended in the production of 1 lb. of aluminium. If a mean pressure of 5 volts is assumed, the theoretical yield should be nearly one-third of a pound more; there is, therefore, some secondary and wasteful action as well as true electrolytic action going on, and room for further economy.

Sodium Extraction.

The experiment by which Davy set free the few minute globules of metallic potassium in the little pool of fused potash has to-day its fruition in the electrolytic process of Castner for the extraction of *sodium*. In the Castner sodium process an electrolyte of fused caustic soda is employed, with an anode of iron and a cathode of copper. The sodium is reduced at a comparatively low temperature, and while in a fused state is run off into moulds. By this process there is produced in one works 260 tons of sodium a year.

Sodium is also extracted electrolytically in Germany, and, I believe, in America. The electrolytic process of sodium extraction is so much more economical than the chemical process as to have almost completely displaced it.

Electrolytic Alkali Production.

I now come to perhaps the most important of all the applications of electro-chemistry at present engaging the attention of chemical and electrical engineers, namely, its application to the alkali manufacture.

There are now several processes in commercial operation for the production of caustic alkali, and chlorine from brine.

In the process of Holland and Richardson brine is electrolysed in a tank divided into anode and cathode compartments by impermeable partitions reaching nearly down to the bottom of the tank. The anode compartment is enclosed, and provided with a flue for conducting the chlorine to bleaching powder chambers. Carbon anodes and iron cathodes are used. During electrolysis the caustic alkali formed at the cathode dissolves, sinks down to the bottom of the tank, and is drawn off; this alkaline solution is subsequently evaporated and fused.

A somewhat similar process has been introduced by Messrs. Hargreaves and Bird for the manufacture of bleaching powder and alkaline carbonates.

In the process of Hulin—in which brine is electrolysed for the process of soda and chlorine—the anode and cathode are both of carbon, but the carbon cathode is in the form of a thin porous partition. The peculiarity of the process is the percolation through the cathode partition of the stratum of the electrolyte in contact with it. This portion of the electrolyte is most strongly charged with alkali, and is forced slowly through the diaphragm by slight pressure on the surface of the bath, caused by restraining the escape of chlorine.

In the processes described, considerable loss and many disadvantages arise from imperfect separation of the products of the electrolytic action at the anode and cathode. There have been a number of inventions with a view to avoid this defect. The apparatus of Castner and Kellner is one that grapples with the difficulty in a most ingenious and effective manner, and it is especially entitled to notice because it is already in extensive commercial use. 10,000 tons of caustic soda and over 20,000 tons of bleaching powder will be produced by it this year.

The elementary apparatus consists of a shallow rectangular slate trough, divided into three compartments by two partitions. These cross the trough from side to side, but do not quite reach the bottom, which is grooved to form a shallow gutter under each partition. The partitions dip into the gutters sufficiently deeply to ensure complete isolation of the three compartments when the gutters are filled to the level of the bottom of the trough with mercury. During operation the mercury not only fills the gutters, but extends in a thin stratum over the bottom of the trough. The trough is so mounted that a slow and extremely slight oscillatory movement is given to it. This results, when one end is tilted up, in the stratum of mercury on the bottom running out of the upper end compartment into the middle compartment. The alternate rise and fall of the ends of the trough is so small that the movement is almost imperceptible, but it is sufficient to cause the mercury in the compartment at the raised end to run into the middle compartment, and that from the middle compartment into the lower end compartment; that is to say, there is an alternate flow of mercury from end to end, which alternately leaves the raised end compartments denuded of mercury, but the floor of the middle compartment and of one of the end compartments are always covered with mercury. The grooves into which the partitions dip always contain mercury, and completely prevent the mixing of the electrolyte in the three compartments. The two end compartments contain brine and carbon anodes, and the centre compartment an iron cathode and water. The anode compartments are covered with glass, and provided with pipes for the conveyance away of chlorine to bleaching powder chambers. During the working of the process, sodium is deposited upon the mercury, with which it instantly amalgamates; the tank is then tilted until the mercury in an anode compartment runs into the cathode compartment, where the sodium is oxidised and dissolved by the water. The current generated by the oxidation and solution of the sodium helps to reduce the power required for electrolysis; for it will be seen that the sheet of mercury lying on the floor of the trough and divided by the partition is always negative in the end compartments and positive in the middle compartment relatively to the opposed electrodes.

The chlorine evolved at the anode is, so far, entirely used for the manufacture of bleaching powder. The caustic soda produced by this process is of great purity.

Closely resembling the Castner-Kellner apparatus is that lately invented by Rhodin, in which the mercury-sealed anode compartments are capable of being rotated, and the construction is such that external heating may be applied, a higher current density employed, and such temperature conditions maintained as are necessary for obtaining the best result.

Electrolytic chlorine is also extensively applied to the production of chlorate of potash. The manufacture of chlorate of potash by electrolysis is performed in a tank divided by a porous partition, with very thin iridio-platinum anodes and iron cathodes. The electrolyte in the anode compartment is usually a solution of chloride of potassium maintained at a temperature of 45° to 50° C. The solution from the cathode compartment containing caustic potash is continuously supplied to the anode compartment, where the potash absorbs the chlorine, with the production of hypochlorite, which is almost immediately decomposed, with the formation of chloride and chlorate of potassium. The chlorate is removed from the electrolyte in crystals. The yield of chlorate of potash is about 1 lb. per 5 electrical horse-power-hours—nearly 45 per cent. of the theoretical amount. In Switzerland and in Sweden chlorate of potash is now largely produced electrolytically by water power. I am informed on very good authority that preparations are in progress for a large increase of production, and that there is no question as to the electrolytic method entirely superseding the purely chemical method.

Electro-thermal Processes.

The electro-chemical processes I have so far described or referred to are all of them of the electrolytic kind. There are other electro-chemical processes which are not electrolytic, but which are important, and deserve mention. I refer, in the first place, to a group of processes and effects which depend on the principle of dissociation and combination at extremely high temperatures, and which involve the employment of the electric furnace, first suggested and applied experimentally by Sir William Siemens.

In this class is included the electro-thermal manufacture of phosphorus; also that most useful and interesting polishing and cutting material next in hardness to the diamond, carborundum—the invention of Mr. Acheson.

Mr. Acheson has developed the size of the electric furnace to enormous proportions, and made it yield results of great industrial value. Amongst these I must mention incidentally—for it is not a chemical, but a physical action—the complete transformation of amorphous carbon into graphitic carbon. It is not new to produce this transformation on a small scale, but to completely convert large masses of carbon into graphite is both new and of great importance.

It is well known that blocks of carbon as ordinarily manufactured, when used as anodes in an electrolytic cell, rapidly disintegrate; and until now this has been a serious difficulty in the construction of electrolytic apparatus like that of Castner-Kellner. This difficulty is completely met by the use of graphite anodes, into which ordinary amorphous carbon anodes are now being transformed by the electric furnace.

Some idea of the scale of these electric-furnace operations may be formed when it is realised that 1,000 electrical horse-power for 36 hours is expended in one heating.

To the same class of electro-thermal products belong carbide of calcium and a great number of analogous products, first obtained by M. Moissan by means of the electric furnace, employed with the most admirable skill, guided by thorough scientific knowledge, and the exercise of that kind of imagination which apprehends and realises far-off possibilities. I am informed by Mr. Worth, of the Acetylene Company, that carbide of calcium is now being manufactured at the rate of probably 20,000 tons per annum. Considering the value of this substance as a means of easily generating the highly illuminating gas, acetylene, and other products, there appears to be great probability of this manufacture becoming much larger.

Ozone Manufacture.

I must not omit to mention a quite different order of electro-chemical effects, in which alternate or intermittent currents of high tension are employed to induce the formation of ozone. By means of ozone, secondary chemical effects of great value are obtained; among these I may mention the manufacture of vanillin and heliotropine, now established manufactures.

Ozone has also been applied to wax bleaching, and to the thickening and bleaching of oils, and to a number of other important uses.

Prospects of the Electro-Chemical Industry.

Although I have but touched the fringe of this matter, I will not weary you with further examples of the value and extent of the applications of electricity to chemical manufactures. I have shown that already there is a large amount of valuable electro-chemical work being done, and that there is a limitless prospect of expansion.

Looking at the immediate future, many interesting questions present themselves, which must be considered, even though we may not be able to completely answer them. Amongst these are the questions, To what extent, and in what cases, are electro-chemical methods likely to supplant old-established chemical methods? And it is not too soon to ask where, and by what means, will the new electrolytic manufactures be ultimately carried on?

Will the introduction of electro-chemical methods of manufacture uproot the old manufactures from their ancient habitat?

In the time that has passed, Britain has enjoyed in chemical manufactures a great advantage in the possession of an abundance of coal.

We are about, in some measure, to lose the benefit of this advantage through the innovations of electro-chemistry.

Whether we profit or lose by the change, largely depends on our readiness or unreadiness to adapt ourselves to the new order of things.

Whatever happens, nothing can be more certain than this—that the electrical engineer who adds to the ordinary knowledge of his profession a competent knowledge of the principles of electro-chemical practice in manufacturing operations, is thereby making broader and surer his path to success.

Addendum—Ratio of Cost of Power to Production in Electrolytic Manufactures.

Material.	Electrical Horse-Power-Hours consumed in the Production of 1 Lb.	Cost of Power to produce 1 Lb. with 1 E.H.P. at £5 and £10 a Year.

PHYSICAL SOCIETY.

Ordinary Meeting, January 21st, 1898.

Mr. Shelford Bidwell, President, in the chair.

Prof. Fitzgerald exhibited some photographs by Mr. Preston in illustration of the Zeeman effect for various cases, including those of iron, cadmium, zinc, and sodium. These photographs, and the method of obtaining them, have already been described. The cause of doubling is now attributed by Prof. Fitzgerald to absorption by the surrounding vapour. In a particular case he examined a double line that exists in one of the photographs. Under the polariser the two lines are at first distinctly seen; but when the polariser is turned, a thin line appears in the middle, and this central line is therefore circularly polarised in a direction opposite to that of the outer pair of lines. The reason for the appearance of doubling in the first position of the polariser is that the central line is there completely absorbed out by the surrounding vapour.

Prof. Oliver Lodge then gave a communication concerning his work on "Electric Signalling Without Connecting Wires."

From the nature of the oscillatory disturbances emanating from any of the customary forms of Hertz vibrator, syntony has hitherto been only very partially available as a means for discriminating between receivers. There is, in fact, so rapid a decrease in the amplitude of the vibrations that almost any receiver can respond to some extent. Discrimination by syntony is possible with magnetic systems of space telegraphy where the magnetic energy much exceeds the electric, *i.e.*, as between two separated inductive coils; and by the use of such coils, appropriately applied, the author has been able to attain fair syntony even with true Hertz waves—*i.e.*, he has constructed spark-gap oscillators, with sufficient persistence of vibration, and syntonised resonators. The "coherer" principle can be applied to either a purely magnetic or to the Hertzian system. It was first used by Prof. Lodge in devising lightning guards, and afterwards in his magnetic system of telegraphy by inductive circuits, each in series with a Leyden jar; a pair of knobs in near contact, or other overflow gap, being provided in the receiving apparatus. This was the first meaning of a "coherer" in the electrical sense, as used by Prof. Lodge. It referred to a *single* contact between two metal knobs. The term has since been extended by others to the filings-tube of M. Branly, and some confusion has arisen, for M. Branly does not consider that simple coherence and break explains fully the behaviour of his instrument. Prof. Lodge is disposed to agree, for he finds that the resistance of almost any form of coherer varies in rough proportion to the received impulses, and that there are other peculiarities (to be mentioned later); he is, therefore, inclined to think that the action cannot, after all, be entirely explained as due to mere "welding," but that there is something more to be learnt about it. The sensitiveness of a coherer depends upon the number of loose contacts; it is a maximum for a single contact, *i.e.*, for a needle-point lightly touching a steel spring. With this sensitive coherer, hardly any "tapping-back" is required for decoherence, but it wants delicate treatment when properly adjusted, and the greatest current through it should not approach a milliampere. On the other hand, a Branly tube rather improves under rough treatment; in such a tube the author prefers to use iron filings in the best possible vacuum; brass too is very good, but rather less easy to manage. Aluminium is thoroughly bad, and gold, for the opposite reason, will not work, its surface is too clean. Points, or small surfaces for making contact with the filings, are better than large surfaces. The usual method of connecting the coherer across the gap of an ordinary Hertz receiver, in parallel with the telegraph instrument and battery, has the unavoidable objection that they shunt away part of the received oscillations. In the syntonic receiver of Prof. Lodge, which contains no gap but a closed wire coil instead, the difficulty no longer exists; for the coherer can now be in series with the detecting instrument, and in so far as these obstruct the oscillations, they may be shunted out in various ways, as the author describes. The main feature of his new systonised vibrators is this self-inductance coil, whose function it is to prolong the duration of the oscillations, and thereby to render syntony possible. Although such a coil acts disadvantageously, in so far as it possesses resistance, the resistance does not increase so fast as the self-induction. The coil should consist of thick copper of highest conductivity, and it should have maximum inductance for given resistance. For similar reasons, the capacity-areas should also be of highest conductivity, their dimensions should increase outwards from the spark-gap as triangles. The receiver must have no gap, it should be accurately bridged over when a transmitter is used as receiver. The limit of speed of response depends upon the telegraphic instrument. Dr. Muirhead adapted a siphon-recorder to the purpose, because it is one of the quickest responders; he arranged it so that it could be used with intermittent currents, direct. Under these intermittent impulses the siphon trembles; and instead of the ordinary siphon-signals, the slip is marked with dots and dashes. Constant mechanical tremor is usually employed for decoherence, but the author finds that decoherence can be brought about by electrical means, without any mechanical tremor, by connecting the coherer momentarily to a circuit less effective as a collector than that of the proper capacity-areas of the syntonised receiver. The battery and galvanometer detector-circuit may be used for this purpose; the coherer being momentarily connected to it, and while so connected letting it experience an impulse from a distance. Prof. Lodge has designed a revolving commutator, by means of which the coherer can be rapidly changed over from the resonating circuit to the instrument circuit, and finally to the "tapping back" apparatus. A coherer is more sensitive when thus isolated and exposed to the full influence of the received oscillations; the subsequent detection of the effect by altered connections is very convenient for laboratory measurements. A diagram of a series of plotted measurements showed that the resistance of an undisturbed filings tube is approximately a direct function of the intensity of the received stimulus, whether successive stimuli increased or decreased in strength. This electrical process of "tapping back" is to be depended upon, but the process long continued fatigues the tube until a mechanical shake is employed to restore it. Large size apparatus made by Dr. Muirhead for actual distant syntonic work was exhibited, and means were shown for protecting and isolating the coherer when its receiving areas were being used as emitters; also a switch used for changing at one moment all the connections from "sending" to "receiving."

Prof. Threlfall said he had come to the same conclusion as Prof. Lodge as to the advisability of diminishing the number of contact points in the coherer. He had endeavoured to produce longer and more persistent waves, and thus to set afield greater effective energy. It was desirable to keep the waves as parallel as possible. He thought there was some probability that the wave-fronts could be altered and rendered more conformable by a process of diffraction.

Mr. Rutherford also had found it best to work with long waves. He fully appreciated the advantage of increasing the capacity of the oscillator by extending the surface of the metallic plates.

Mr. Campbell Swinton asked whether experiments had been made to verify Hertz results as to the influence of reflectors behind oscillators and receivers. He had found them disadvantageous. A single wire behind either apparatus seemed partially to annul the effect. He also asked whether Prof. Lodge had observed the extraordinary sensitiveness of coherers to small changes of current in neighbouring circuits.

Prof. Lodge, in reply, said he had observed the sensitiveness to slight, sudden variations of current referred to by Mr. Campbell Swinton, for instance, when electric lamps were switched on or off. The effect of mirrors had been studied by Prof. Fitzgerald. They required to be of large dimensions as compared to the oscillator and receiver, otherwise the true reflections were not obtained.

Dr. Silvanus Thompson afterwards exhibited a Tesla oscillator. This apparatus is intended to replace the two induction coils and spark-gap arrangements used by Mr. Tesla for high frequency experiments. It consists of an induction coil with a separate self-inductance coil in the primary circuit. This self-inductance coil is also used as an electro-magnet for the separate interrupter of the primary circuit. A condenser is connected between one end of the primary coil and one terminal of the interrupter, so as to include both of them between its terminals. The primary is a single turn of copper strip, six inches wide. The secondary is one layer of thick wire; each turn separated from the next by an air space. The supply current, about half an ampere, may be taken from the electric light mains at almost any voltage from 50 to 200, direct or alternating.

Prof. Lodge said it would work quite well at 10 volts. He pointed out, also, that if the straight discharge rods at the spark-gap were free to slide, the discharge drove them back into their sockets.

Prof. Fitzgerald said it was stated at Toronto that the spark was broken at the interrupter when the condenser was charged, and that by the time the condenser was ready to discharge, the contact at the interrupter had been made again. It seemed to him that the condenser discharges and surgings must take place at a rate far higher than the period of the mechanical movement of the interrupter. The condenser charges and discharges were very rapid. It was not what is ordinarily called the "time constant" that was involved, for that only referred to constant voltage. Here the voltage was changing very rapidly indeed.

Prof. Herschel asked if such an apparatus was suitable for work with Röntgen rays.

Dr. Thompson, in reply, congratulated Mr. Tesla upon the perfect working and compactness of his invention. The present form was not suited for Röntgen ray experiments, but Mr. Tesla had designed a special coil that was excellent for that purpose.

The President proposed votes of thanks, and the meeting was adjourned until February 11th.

NOTES ON THE ELECTRO-CHEMICAL TREATMENT OF AURIFEROUS ORES.

The object of the gold mining industry is to obtain the precious metal from its ores in the simplest, cheapest, and most efficient manner. First, the ores are pulverised, then the gold which they contain has to be absorbed by mercury, or dissolved by chlorine, bromine, cyanide, or their compounds, or by other solvents; then comes the operation for the recovery of gold by distillation of amalgams, precipitation by chemicals, or by electro-deposition.

Is the *rôle* of electricity confined to the precipitation of the metal or does it assist in dissolving gold?

Major-General C. E. Webber, read on the 28th ult., at the Institution of Electrical Engineers, a paper on "Notes on the Electro-chemical Treatment of Ores containing the Precious Metals," in which he says that "the precipitation of gold and silver with the aid of the electric current has a history which may help his audience to appreciate the present situation of a question which cannot be devoid of interest to the members of the Institution of Electrical Engineers."

This preamble sounded well and looked very promising for electro-metallurgists, who expected that some light would be thrown on the influence of electrolysis on auriferous ores in a dissolving liquid containing either chlorine, bromine, cyanide of potassium, chloro or bromo-cyanogen.

Major-General Webber passed in review a legion of patents, and went back to Becquerel (1835), Crosse (1837), Prince Bagration (1844), who "described in the *Bulletin de l'Académie des Sciences de Saint Pétersbourg*, some experiments with finely divided gold dissolved in an aqueous solution of potassium cyanide under the influence of the galvanic current, by which means he precipitated the precious metal on a copper cathode."

With all due respect to the gallant Major-General, this is a little error. Bagration noticed that gold was soluble in an aqueous solution of cyanide of potassium *without*, and not *under the influence* of the galvanic current.

Next comes Rae, whose process is incorrectly described by Major-General Webber, who confines himself to the mechanical details of the electrolytical apparatus, while the only important electro-chemical question is the statement made by Rae, that he made use of the combined action of the current of electricity and of suitable liquids, such as cyanide, so that by the action of cyanide the metal is *reduced*, and can then be collected. What Rae says is that "under the influence of the current, the action of the chemicals is *materially facilitated*, and from the solutions, the precious metals are precipitated on the cathode."

Here we have the whole thing in a nutshell! Does the current aid the cyanide of potassium in dissolving the gold, or is it the cyanide of potassium alone, which dissolves the gold without any aid from the electric current, the action of which is simply to deposit the gold dissolved by the cyanide of potassium on the cathodes?

If the electric current does not accelerate the dissolving action of the cyanide of potassium or other similar chemical agents, we shall have done at once with all the processes in which a gold dissolving bath is supposed to accelerate the exhaustion of the auriferous ores when in conjunction with the electric current. The author has not ventilated this question, and we do not hesitate to say that this is to be regretted.

He tells us, and this we accept as a fact, that the Breakwell and Haycraft electro-amalgamator is a copy of the Rae system, except that they "use *no solvent* of the precious metals present in the mixture under treatment."

There is, however, a little mistake in this statement, since if the cyanide of potassium in Rae's apparatus dissolves the gold, the electric current is merely an agent for precipitation, and it would be much more practical to dissolve the gold in one tank and to precipitate it in another. In an electro-amalgamator, on the contrary, the current helps immensely the absorption by a mercurial cathode of the fine and coarse gold.

It may be that in 1888 "MacArthur and Forrest neglected or discarded the assistance of electricity in combination with a weak solution of cyanide of potassium because of the great expenditure of chemicals which they alleged to be the result," but they know better now, and there are already several MacArthur patents for the electro-deposition of gold from its cyanide solutions.

What is the use of the very dry abridgments of the Body and Hannay specifications?

Major-General Webber states that the Breakwell and Haycraft apparatus is the first example in which the bottom of the vessel, described as of basin shape containing mercury, as in the case of the ordinary amalgamating pan, is also the cathode. Here again he is misinformed; has he never heard of the electro-amalgamator, invented by the French engineer Bazin who died a fortnight ago?

At all events, he ought to know Nolf and Pioche, and also Partz, who, in their well-known electrolysers, used mercury as a cathode at the same time as Rae invented his electro-amalgamator between 1868 and 1869.

Here is a more serious blunder:—Major-General Webber modifies and distorts the text of the Molloy specification and states that "he dissolves gold by means of bromine, chlorine, cyanogen or *other compounds*." Bromine, chlorine, iodine, are not compounds, and the characteristic feature of the Molloy process is the employment of bromine, chlorine, iodine *and cyanogen* or THEIR *compounds* as solvents of gold. Accuracy is as much indispensable as impartiality for critics. If the version of the Past-President of the Institution of Electrical Engineers is correct, how could Molloy maintain that he was the first to think of the bromo-cyanogen as a solvent of gold?

We still fail to see where we are driven by the lecturer, who goes on quoting patents such as that of Kendall, who added barium per-oxide to a cyanide of potassium solution, or to use the *ipsissima verba* of Major-General Webber, who "treated pulverised ores with peroxide of barium and a suitable cyanide in a *water solution!!*"

Then comes Pielsticker, who treats the ores with a solution of cyanide of potassium in conjunction with an electric current of low tension, and with circulation of the liquid through the space between the electrodes which are fixed respectively, the anode to the bottom, and the cathode to the top, of the tank. This time, we were, so to speak, entitled to have the opinion of Major-General Webber on this claim, identical with the theory of J. Rae, viz.: that the precious metals are attacked more energetically by a cyanide solution in connection with a current of electricity than without. But this question appears to be immaterial to the learned author, who simply says:

"To recapitulate: This process has, in common with Rae and his successors, the combination of a solution of potassium cyanide with an electric current, by which it assists solution and effects precipitation on a cathode; and, in common with Molloy, it effects the treatment in more than one stage, and by means of 'circulation.' In this latter respect Molloy and Pielsticker are at one with the process of Siemens & Halske, in contradistinction to the processes in which 'agitation' is essential. With reference to my observations further on as to 'agitation,' it may be here observed that in such processes the density of the sludge at various points in the system of circulation must depend on its rate of motion."

What is the resemblance to be found between the arrangement of Pielsticker, who has a mass of ore between his electrodes, and that of Molloy, who has a layer of mercury over which the gold solution passes, or the large Siemens vats where a large volume of weak gold solution passes between numerous electrodes close to each other, and circulates at a rate of more than 5,000 gallons per hour?

We must congratulate Major-General Webber upon the chivalrous generosity which made him spare us the tedious detailed description of all the existing patents for the use of the electric current in combination with mercury, cyanide of potassium, and halogens. Those processes and their theories are not new things for electricians, and the Institution of Electrical Engineers is not quite the proper place for their discussion. This is not a paper on electro-chemical treatment of ores; it looks more like a report on a mongrel patent with a view to prove that, although there are many breeds in it, as a whole it is not similar to any of them. We can only compare this paper to the "Notes on the Treatment of Gold Ores," a book in which, about 10 years ago, Florence O'Driscoll depicted all the patents for the chlorination of auriferous ores, which he said were superseded by the Newbery-Vautin system, with this difference, however, that the book was extremely interesting, while we cannot say the same of the paper on the electro-chemical treatment of ores, the sole object of which seems to be to enable the author to speak highly of the Pelatan-Clerici process.

"In this we have, I believe, for the first time, a process and apparatus which effectively combines, in a way that can be constructed and worked by a workman of average intelligence, the following:—

"(1) A vat made of a material, dielectric in its nature; (2) an agitating apparatus of various specific forms, each form calculated to carry out one and the same process—being the result of considerable experience—having an agitator, part of which constitutes the anode in an electrolytic circuit, which is carried so that it can by no means make contact with the bottom or sides of the vat; (3) the presence of a cathode, which covers the whole of the bottom of the vat, made of a metal (preferably copper) plate or sheet, and suitably contained and fixed so as to carry on it a layer of mercury; (4) the use of a graduated current from an electrical generator, having large quantity and low potential; (5) the mixture or sludge under treatment being composed of water in given proportions, ore finely pulverised, potassium cyanide or other solvent of gold and silver, and common salt, with the addition as required during the process of alkalies or organic acids as may be required."

We would welcome a paper depicting the progress and the actual state of the electro-metallurgy of gold, or describing a new, simple, and original process for the extraction of the precious metals from their ores, but this lengthy panegyric of an electro-cyano-chloro-mercurial method does not contain much beyond the ancient history of patents which have been dead, buried and forgotten for a long time, to which are added the descriptions of the Molloy, Hayward, Danckwardt, Clark, Keith and other apparatus, and finally of the

Pelatan-Clerici installation. Here and there are a few chemical equations with which every electro-chemist is acquainted and which are to be found in specifications or in books on electrolysis, and also a little dissertation on the fouling of mercury.

This evidently is the electro-chemical budget of the report, and it strikes us at almost every paragraph that we have already read it somewhere. With regard to the Pelatan-Clerici process itself, nothing can be said in favour of a combination of ores, kept agitated over a mercury cathode in a solution of cyanide of potassium and chloride of sodium.

It is a complication more than an improvement; Major-General Webber has valiantly made great efforts to prove that his favourite system is different from the others which he has described, and we do not pretend that he has not succeeded in doing it, but he has altogether failed in his attempt to show that, from the technical point of view, the Pelatan-Clerici apparatus is constructed according to the canons of electro-metallurgy. We sincerely regret to have to perform the unpleasant duty of criticising this lecture, but we do not see how we could have acted differently: silence would be interpreted as the recognition of the excellence of a process which no competent man will recommend as a sound application of the electric current to the extraction of gold. We do not, in any way, say that the Pelatan-Clerici system is not an effi ient one, that it does not extract the maximum of the precious metals contained in the ores; we vaguely know that it has been worked about two years at the Delamar mine; its merits or demerits as a gold extractor have nothing to do with us, we simply look on it as an electro-chemical apparatus, and it strikes us as being a very faulty one, almost as bad, and perhaps worse, than those in which carbon anodes are used as stirrers of the ore. In the present case we have a metallic agitator which acts as an anode, and the sole fact of using a metallic anode in hard and constant contact with the ores in a solution which consists of chlorine and cyanide of potassium, is a breach of the laws of commercial electrolysis, especially when currents, such as those stated by Major-General Webber, pass through the electrolyte. He finds it quite natural that the potential must be between 5 and 14 volts for a vat of 9 feet interior diameter, capable of treating 2½ tons of ore per shift of 12 hours, total 5 tons per day of 24 hours, and he informs us that the potential must be governed by resistances "fixed" in the circuit of each vat.

He further makes this remark that "the quantity is regulated by the resistance in that part of the external circuit which lies between the electrodes. Provision is made for a minimum quantity of 1½ amperes per square foot, being half the sum of the cathode and anode together in square feet," thus, if that area is equal to 52 square feet, the current should not be less, and not much more, than 39 amperes.

When the voltage is high and the current heavy, there is no economic extraction of gold and there is no good deposition of gold.

Evidently there is something wrong in such an arrangement; a rather large proportion of cyanide of potassium is used; then some specific oxidising agents and chloride of sodium are added to increase the conductivity: and, nevertheless, this electro-chemical process requires 14 volts and 1½ amperes per square foot. This is preposterous! And, leaving aside the question of the enormous consumption of cyanide of potassium, no man who understands the application of electricity to the extraction of precious metals, would, for a moment, entertain the extravagant idea of adopting such an electrolytic apparatus, in which the expenditure for the electric current is considerable, and, besides, necessitates a costly installation of motive power for stirring the ore in the vats.

We do not insist on the drawback of the agitation of the ores; we do not even ask whether or not the quicksilver is broken up by the sand with which it mixes, with subsequent loss of mercury and gold; but it does not seem that Major-General Webber has gone very deeply into the investigation of the electro-chemistry of the process. We do not even discuss the value of the following theory:

"The expressions I have used—namely, 'reduction of resistance' and 'increase of conductivity'—are useful because they are easily understood; but, be it remembered, they are not correct as applied to the solvent, *i.e.*, water. Indeed, these descriptions of the effect of the mixture of sodium chloride in a solution, and then placing that solution between an anode and a cathode, is scientifically inaccurate. What happens to the sodium chloride in solution in the water is, that it is disintegrated and re-formed, and thus it becomes the intermediary by which, at the instant that chlorine gas and sodium are set free, the current is enabled to 'communicate' between the electrodes."

Each one of those who listened to the paper know what takes place in the electrolysis of a chloride of sodium solution in presence of mercury cathode. We also know, as Major-General Webber says, that: "In the first place, one might expect the nascent chlorine to attack some of the baser metallic ores present in a finely divided state. For instance, sulphides, selenides, arsenides, &c., often attached to particles of gold or silver, would be so attacked; the chlorine uniting with the metallic base iron (Fe) or copper (Cu)." But what we are certain takes place at the same time, is the corrosion, disintegration and destruction of the metallic anode. With such a powerful current as the one used by Pelatan-Clerici, the anode cannot last long.

There would have been a really startling actuality in the "Notes on the Electro-chemical Treatment of Ores" if Major-General Webber had introduced in his memoir the subject of the two electrolytic methods for which their respective promoters claim at present the most marvellous properties. One is the Electro-bromine process which would have evidently called for some instructive comments, the other one is the Chloro-cyanide method, which would suggest many interesting remarks. As they are, the "Notes on the Electro-chemical Treatment of Ores" do not seem to present an essential character of utility for the electrical profession.

A SURVEY OF THE POSSIBILITIES OF ELECTRIC HEATING AND COOKING.*

By W. P. ADAMS, A.K.C., A.I.E.E.

My desire this evening is, if possible, to pave the way to a better understanding of the possibilities of electric heating so that engineers may be able to assume that confidence as to its merits which is necessary before any real progress can be attained, and which is at present lacking in many a professional mind. The feeling is general that the cost is, and will be to the end of the chapter, so great that its adoption can only be hoped for by those of more than ample means, but I hope to show that, while it undoubtedly deserves to rank as a luxury, it will be well within the means of those with average incomes when the cost of current is somewhat modified. The reason why electric heating, more especially in the direction of cooking, is able to compare favourably with other methods, is, that the heat can be applied just where it is required, and there is remarkably little waste.

Heating appliances do absorb what appears to be a large amount of electricity, and many electricians, especially those more closely connected with electric lighting, are surprised at the large amount of current which is necessary for cooking purposes, and mentally compare what might be done with the same current if devoted to the production of electric light.

As it is in the direction of electric cooking that I anticipate the largest development in the near future, I shall confine myself at first to a consideration of this subject.

In a kitchen suitable for supplying the needs of a family of from 8 to 10 persons the following apparatus would be necessary: Oven, absorbing 2,500 watts when heating up for about 15 minutes, and on the average about 1,200 watts afterwards. Breakfast cooker, wound for two circuits, each absorbing 600 watts. Two grillers, each wound for 500 watts. Two frying-pans, also wound for 500 watts, and several hot plates for warming ordinary saucepans, or in place of these several self-contained electric saucepans. These plates or saucepans would probably absorb 1,500 watts together. The household supplied from such a kitchen would probably have a maximum demand for not more than 2,500 watts for lighting purposes. The total watts which could be absorbed by the cooking apparatus is 7,200. It must, however, be borne in mind that these various appliances are used at different times, and never altogether.

We shall now consider the difficulties in the way of the adoption of electric cooking. First and foremost is the question of the cost of current. This is all important. In addition to this the first outlay cannot be overlooked, owing to the rather high cost of the apparatus.

The largest field for the development of electric cooking is undoubtedly in private houses supplied from central stations, and if there is to be any large extension in this direction the central stations must be prepared to supply current at a more moderate price than is now charged for lighting. It is generally recognised that electric cooking will eventually prove to be the means of solving the much-vexed question of securing a day load for central stations; and, in view of this fact, many of the central stations offer special terms for supplying electric currents for heating. A number of the central station engineers are, however, still doubtful as to the advantage of adopting electric heating, partly owing to the question of the load overlapping the lighting load. This question I shall touch on later, but I would venture to point out that, if the demand is spread over a sufficient number of hours, electric heating is worthy of consideration quite apart from electric lighting, and it would therefore pay to put down extra plant to meet the additional demand. In fact, I do not think the day is far removed when the demand for current for electric heating will vastly exceed that for lighting purposes; and I submit that the solution of the question lies mainly in the hands of the present suppliers of electricity. If they are prepared to adopt a liberal policy of supplying electricity for heating purposes, perhaps at little more than the actual bare cost, they will very soon find that the improved conditions under which they run their plant will begin to repay them handsomely.

The price to be charged is of the greatest importance, and I will, therefore, make a few comments upon the methods of charging now in vogue. It is becoming usual to make the charge for heating and power about half that made for light. A very usual figure is 3d. per unit, while some supplies have brought the price down to an even lower figure. I may say at once that the ideal to be aimed at for heating and power purposes is a charge of 1d. per unit, and although it is only possible at present for one or two companies to charge such a figure and cover the bare cost of production, I think the figure is well within the range of practicability, and with a rapidly growing load on supply stations, I think it will soon become general. It is noticeable that the local authorities are moving more rapidly in this direction than supply companies. I would commend this to the attention of the supply companies. Their policy of making high charges is, to say the least of it, unprogressive. Only about four are charging so little as 3d., while 26 of the local authorities supply at 3d. or less, 13 of these charge 2½d. and less.

The Wright system of charging for electricity appears to be securing considerable support amongst central station engineers, and the maximum demand system seems to have been receiving even greater favour. With both of these systems I can foresee a trouble in connection with the supply of electricity for heating purposes.

Under the Wright system it is conceivable that the demand meter

* Abstract of paper read before the Northern Society of Electrical Engineers.

may run up to a most unusual height, through the inconsiderate switching on of a number of the heating appliances together, the indicator therefore furnishing quite an abnormal record upon which the charges are to be based. Again, with the maximum demand system, if the charges are to be made upon the usual understanding that the whole apparatus is to be run for an hour at the maximum charge before any reduction is made, the charge cannot come down to anything like a reasonable figure. It is, of course, obvious that the whole of the appliances will not be in use together, and I think this point is worthy of close consideration.

In a certain kitchen it was found that the various cooking appliances were in use for from five to seven hours a day, during which time the highest point reached was 1·5 kilowatts. The average consumption during the day was from 8 units. It will thus be seen that if generating plant to the capacity of 2 kilowatts was installed for supplying these cooking appliances, it would have an earning capacity of about 1,400 units per kilowatt installed per annum.

I find that the number of units sold per annum per kilowatt of plant installed varies considerably among the different stations in country towns where the load is almost exclusively a lighting one and the supply is very small during the day time; about 400 or 500 units represent the work done during a year by one kilowatt of plant installed. In the larger towns, where there is probably a small day supply for power as well as one for lighting in dark offices and basements, the demand is larger. In Brighton, 840; Edinburgh, 640; Glasgow, 696; Manchester, 700. It will be seen that Brighton, which might also be termed a country town, as there are no factories there to absorb power in the day, shows the best results of those named. This, I think, is traceable to the moderate nature of the charge for current.

As a load for summer time, cooking should prove invaluable to supply stations, and the question of overlapping during this period does not arise.

In winter, however, the conditions will be different. A certain amount of overlapping will occur owing to the prevailing fashion of late dinners, but I submit that the load for electric heating is likely to be of sufficient importance to warrant putting down additional plant to meet this.

Much, of course, depends upon the acuteness of the peak as to how this question is to be met. If it can be arranged, it will be desirable to utilise for heating during the day the plant installed for lighting purposes, but if the demand for heating grows to such an extent as to greatly surpass the lighting load, the question becomes of less importance. It is not, perhaps, within my province at this moment to suggest how this difficulty is to be met, but with some stations in this country the question does not arise at the present time, as ample plant has been installed to meet the lighting requirements and still leave a balance in hand to allow for the overlapping. A number of stations appear to be provided with twice the amount of plant required to meet the maximum demand. Of course, some portion of this is reserve plant, but there still remains a good balance in hand to meet this contingency.

I am inclined to think that a secondary battery would prove of great value in meeting the peak difficulty, as there are several depressions on the day load curve which could be filled up if the generating plant were employed during these times of light load for charging the accumulators. How far it is possible to economically utilise accumulators for this purpose in alternating supply stations is an open question.

While considering the charges made by the various supply companies it is noticeable that several have adopted the enlightened policy of charging for power and heating purposes, a price which is actually less than the total works' cost. Putting on one side for one moment the question of overlapping, it is obvious that this is a right policy to adopt, as, assuming that the plant used for lighting is employed for supplying heating appliances, the charge for rent, management, &c., will remain practically the same.

I have the misfortune to be situated in a district served by the City of London Company, which company holds a monopoly and takes advantage of this to maintain a charge which is worthy of the very early days of electric supply. Although their works' cost compares anything but favourably with other large towns, having in many cases a much smaller output, I think you will agree with me that the charge of 8d. is somewhat extravagant, and I may say that such a charge absolutely prohibits any demand for current for power and heating purposes. It is true that a rebate is made if more than a stated quantity of electricity is used, but this is fixed so that it is of little value in the way of reducing the price.

It seems almost incredible that, in these enlightened days, the foremost city in the world should be one of the worst supplied in the matter of electricity.

I have so far made no comparison between the cost of cooking by electricity and that by other means. I shall not deal with this question much in detail, as I think it more practical at the present time if a general idea is given as to what the actual consumption of electricity will be, for the cost by other means varies largely under different circumstances. I have, however, some figures to hand obtained in a kitchen where both gas and electricity could be used at will. The household was a small one, consisting of about five persons, and the consumption of electricity was approximately 30 units per week when cooking was done solely by this agency. When gas was employed exclusively, 1,240 cubic feet of gas were used during a week. The cost, then, of electricity at 2d. per unit is 5s. a week, and of the equivalent amount of gas at 3s. per 1,000 cubic feet is 3s. 9d.

The figures of consumption which I have given above are the most complete at my disposal, and this is my reason for bringing them before your notice, but I have other results to hand which indicate that the consumption of current may be reduced below the figures given when the appliances are used intelligently and with care. For small installations such as we have considered one may assume roughly that a unit per head per diem will suffice for all cooking purposes. These figures will naturally be reduced in larger establishments and experience seems to point to about 1s. 2d. a unit as a sufficient allowance in kitchens where more than 30 or 40 persons have to be provided for. The best results will be obtained where there is a hot water supply. Many of you are probably aware that heating water by electricity is a most uneconomical proceeding, at any rate at the present prices, and where an establishment is sufficiently large it is always recommended that a slow combustion stove is fitted to supply all the hot water for the household. In many houses such a stove is already fitted.

(*To be continued.*)

THE PACIFIC CABLE.

LETTER TO THE RIGHT HONOURABLE SIR WILFRED LAURIER.
BY SIR SANDFORD FLEMING.

Ottawa, *December 28th*, 1897.

The Right Honourable Sir Wilfred Laurier, Premier.

Sir,—For some months past I have frequently been asked by writers of the press to furnish information respecting the Pacific cable. I have been so applied to, as it is well known that I have long felt the deepest interest in the project, having been appointed by the Canadian Government to take part in the Colonial Conferences of 1887 and 1894, and in the Imperial Committee of 1896. I have invariably declined to comply with the request from the feeling that it was distinctly understood that the proceedings of the investigation by the Imperial Committee should be treated as confidential until made public by Her Majesty's Government. I have, in consequence, felt debarred from alluding either to the evidence obtained by the Committee or to the conclusions submitted in their report, or in the special reports presented to the Canadian Government by the Canadian Commissioners and by myself.

These several documents were presented nearly 12 months ago; since then questions have arisen, which were not considered by the Imperial Committee, and many important facts are also obtainable from other sources, explanations respecting all of which should, I conceive, be communicated to the public.

Since the Imperial Committee closed its investigations, the Conference of Colonial Premiers has been held in London. Among other matters, the Pacific cable was brought before this Conference, and from what has transpired the subject was complicated by a new proposition having been submitted by the Eastern Extension Telegraph Company. Consequently, the consideration of the project was deferred. Six months has since elapsed, and I feel called upon to make known some facts and explanations bearing on the questions which, in my humble judgment, the public should understand. I trust you will approve of the information being given to the public in the form I have now to submit to you.

I have the honour to be,
Your obedient servant,
SANDFORD FLEMING.

THE PACIFIC CABLE.

Everywhere it is apparent that the British Empire is being formed by a process of growth and development, and there are many forces actively in operation, all tending to give it shape and strength and distinctive character. Lofty ideals are entertained by men of thought, experience and patriotism; but the future is veiled from us, and we cannot foretell the precise form of relationship which will eventually be assumed by members of the British family of nations in so many meridians of longitude.

If the form of the development to be attained is not clearly foreseen, it can at least be said that the entire British people in all parts of the globe are inspired by a unity of sentiment, and that they are simultaneously moving onwards in one general direction. Progress is the watchword in all quarters. It is impossible not to recognise the advancement perceptible in the colonies of the southern seas, and equally the amazing vitality in British Africa. The Dominion of Canada plays an important part in moulding the destiny of her own people, and in promoting more intimate relationships between the motherland and the colonies.

It is but 30 years since the scattered provinces of British North America became federated in one government. The Dominion thus created inherited many remarkable advantages. It can lay claim to the most important geographical position, owing to its extension between the two great oceans; a position which confers the only means of establishing under the British flag communications between the eastern and western territories of the globe. It enjoys the possession of vast fields of the richest virgin soil, with still unexplored mineral regions of immense extent, and presumably of immense value. The population retains the high qualities of the foremost nations of western Europe, from which it has sprung, and the wide expanse of unoccupied areas leaves ample room for a large accession to its number. These rich possessions of the Dominion give promise, under wise guidance, of a splendid future.

It soon became evident that the development of a country continental in its extent exacted public works of corresponding magnitude. Lines of railway and telegraph were projected from ocean to ocean, and immediately after Confederation, both were proceeded with. In 1874 the policy of establishing the telegraph in advance of the railway was determined upon, and as a corollary to the trans-continental telegraph the proposal to extend the electric wire across the Pacific naturally followed. It can be said that ever since the telegraph reached the coast of British Columbia the Pacific cable has engaged public attention, and that the necessity of this undertaking has been repeatedly affirmed. It received recognition in the Conference of Representative Colonial Statesmen in London in 1887, in that of Ottawa in 1894, at telegraph and postal conferences in Australasia almost annually, and at various times by Chambers of Commerce at home and abroad.

The dominant idea with those who have most strongly advocated the establishment of a Pacific cable has been the unity of the Empire. They foresaw the difficulty of effecting any practical union between communities separated by distance, so long as they remained without the means of direct and cheap communication. At the same time it was plain to them that a telegraph across the ocean would foster trade and commerce—the life of an Empire such as ours.

Among the memorable gatherings of representative men, not the least important was the Conference of Premiers in London on the occasion of Her Majesty's Diamond Jubilee. Before these statesmen met, hopes had been entertained that some definite action would be determined for the inauguration of the scheme. Preparations had long been made for joint action. It was one of the chief objects set apart for special consideration at the conference of the Imperial and Australasian Governments held at Ottawa in 1894. With this view, the Canadian Government, agreeably to a resolution of the Conference, obtained much information on the subject, and transmitted it to all the governments interested in the projected work. Soon afterwards the Secretary of State for the Colonies (Mr. Chamberlain) invited the Canadian and Australasian Governments to send representatives to London for the purpose of taking part in an Imperial Committee to be appointed specially to receive evidence and consider the project in every detail. The Committee first met on June 5th, 1896, and on January 5th, 1897, they reported the results of an exhaustive inquiry.

The proceedings of the Committee and the conclusions which have been formed have not been made public. They have been repeatedly asked for, but as nothing transpired respecting the labours of the Committee up to the Jubilee week, the opinion gained ground that when the Conference was concluded full information would be given to the public with the decision arrived at by the imperial authorities and the Colonial Premiers. In many quarters it was expected that action would on that occasion be taken, and that the inauguration of the cable would result as a practical outcome of the Queen's Jubilee.

The old proverb tells us that it is often the unexpected which comes to pass. The proceedings of the Conference of Premiers were first made known to the public by an article purporting to be published by authority in the London *Standard* of July 25th, and the subject of the Pacific cable is thus alluded to:—

"The Conference left the Pacific cable scheme in mid-air, and it is very unlikely that anything more will be heard of it for a considerable time. The position was entirely changed by a proposal by the Eastern Extension Telegraph Company to lay an all-British line from Western Australia across the Indian Ocean to Mauritius, thence connecting with the Cape and St. Helena and Ascension. . . . . The Eastern Extension Company, it is understood, does not ask for a direct subsidy for the new lines, but seeks other concessions from the Australasian Governments which, if made, will justify them in proceeding with the work."

In the account of the Conference of Premiers laid before the British Parliament, there is a reference, in two sentences, to the cable, no mention, however, is made of any proposal having been submitted by the Eastern Extension Company. But the Premier of New South Wales (Mr. Reid) returned home from England through Canada, and being interviewed by reporters in Montreal, Toronto, and Vancouver, confirmed the statement with respect to the proposal of the Eastern Extension Company. The character of the concessions asked by the company has not been made public, but it has been stated that they desire to obtain exclusive rights for Australia on condition that they connect the colonies with the Cape and lay a new cable from the Cape to England *via* St. Helena, Ascension Island, Sierra Leone or Bathurst and Gibraltar. This scheme is put forward by the company as a substitute for the Pacific cable.

Owing to the fact that telegraphic connection with the Cape is at present extremely defective, the proposal of the company is undoubtedly of great importance to South Africa.

There are two telegraphic routes from England to Cape Colony. Both have landing stations at Lisbon, one passes through the Mediterranean to Alexandria, through Egypt to Suez, through the Red Sea to Aden, and from Aden the cable follows the east coast of Africa, touching among other points at Mozambique and Delagoa Bay in foreign territory. The other route leaves the first at Lisbon, and follows the west coast of Africa, touching at some 14 points; eight of which are under foreign flags, those of Portugal, France, and Spain.

Interruptions are frequent on both routes. There is evidence to establish that during the past four years communication between England and the Cape has been broken many times, and that the aggregate interruptions have averaged in each year 75 days on the west coast route and 87 days on the east coast route, showing that each cable is unavailable from six to seven days per month. While this refers to the average period that the cables have been thrown out of use, the durations of single interruptions have varied from one to 30 or 40 days. As both lines are liable to be broken at the same time serious inconveniences have not seldom resulted. Everyone will remember this contingency occurring when the Transvaal difficulty was at its height. Intense anxiety was then caused during the cable interruption of 11 days, when South Africa was passing through an acute crisis in her history.

Obviously a new cable to the Cape is much required, and as the frequent interruptions to traffic by the two present routes is to a large extent owing to the fact that the cables are laid in the shallow water which prevails along the African coasts, they are in consequence exposed to accidents to which cables in deep waters are not subjected. That part of the proposal, to touch at St. Helena and Ascension, where the water is of ample depth, would give to the cable the necessary security and avoid the difficulties experienced on the present routes. It is, however, not so clear that the northern half of the new cable would be so fortunate. By landing at Sierra Leone or Bathurst and Gibraltar, and terminating in Cornwall, the cable of necessity would be laid for some distance in shallow seas, where it would be exposed to injury from various causes, and where, too, the agent of an unfriendly nation, or, indeed, an evil-disposed fisherman, would have it in his power to destroy the cable with ease, totally unobserved. For hundreds of miles it would be exposed to such risks.

The question may be asked, would not this proposed new cable from England to the Cape, with an extension to Australia, be of general advantage? To such a question there is but one answer. It certainly would be of general as well as special advantage, for the reason that we cannot have too many lines of communication. They are needed in the every-day business of trade and shipping, and moreover, we must come to recognise that a complete telegraph system, ramifying wherever Her Majesty's wide domain extends, is an essential condition of the life and integrity of the British Empire. It is on this, and on other grounds, impossible to admit the claim of the Eastern Extension Company, that the proposal submitted by them is preferable to a trans-Pacific cable, and that it will render it unnecessary.

At the Colonial Conference of 1894, the outline of a telegraph system for the Empire was submitted. It was not confined to one side of the globe; the system projected, embraced, and encircled its whole extent. The scheme was illustrated by a map of the world, with the chief cable lines laid down upon it. If the proceedings of the Conference be referred to, it will be seen that a trunk line of telegraph was projected from London through Canada to Australasia, with extensions to South Africa, India and China. It was shown that by the Canadian route all the chief British possessions on the four continents would be brought into electric touch with each other, and with the Imperial centre in London. It was demonstrated, moreover, that this result could be accomplished without touching a single acre of foreign soil, and without traversing shallow seas, where cables are most liable to injury from ship's anchors and other causes, and where they can be so easily fished up and destroyed. No fact can with greater confidence be affirmed than that the cables by the Canadian route would be far less vulnerable than the existing cables, or those now projected by the Eastern Extension Company. But even if no advantage in this respect could be claimed, it requires no argument to prove that telegraphic connection between England and Australasia would be infinitely less subject to interruption from accident or wilful injury, by having the Canadian line established, in addition to the Eastern Extension lines, especially as the former would be on the opposite side of the globe, and far removed from the immediate theatre of European complications.

It is not possible to believe that anyone disassociated from, and uninfluenced by, the Eastern Extension Company, can view the proposed Canadian Pacific cable with disfavour. If it be important to strengthening the connection between the United Kingdom and the out-lying portions of the Empire, no one can question its necessity. But the Eastern Extension Company has never taken a friendly view of the Pacific cable. From the first it has been its determined opponent. The proceedings of the Colonial Conferences of 1887 and of 1894 give evidence of this fact. The report on the mission to Australia by the Canadian delegates gives some indication of the intense and persistent antagonism displayed by the company, and the manner in which its powerful influence has been employed to thwart the enterprise. It may not be an unwarranted surmise that the immediate purpose of the company in submitting to the Conference of Premiers their new proposal was to divert attention from the Pacific cable.

(*To be continued.*)

ELECTRIC LIGHTING AND DUST DESTRUCTORS FOR GLOUCESTER.

The vexed question of the selection of site for the proposed electric light works for Gloucester came before a meeting of the City Council again last week. The matter has been under the consideration of the Council for many months, and even now an essential and governing factor, viz., as to whether electric light works and dust destructor shall be erected in combination, or otherwise, has not been determined. Mr. Hammond, the consulting electrical engineer, attended the Council meeting, and stated that he had, at the suggestion of the Mayor, inspected the sites which had been pointed out to him. With regard to some of them, they were confronted by the question as to the advisability of separating the two projects. At the present time the Council appeared to have made up their minds that the electricity works and the dust destructor should be combined, and it was useless for him to go on viewing sites which were condemned if the decision of the Council were adhered to. If he might venture to say a word on the point, he would recommend them to avoid going past the best site, or what was approximately the best site, for the electricity works, for the sake of the dust destructor, and, although, as he had already pointed out, there were advantages in the combination, yet they might run that combination too far. Personally he would rather not have the dust destructor next door to his electricity works, for the one reason that the dirt and dust made it more difficult to carry the electricity works on with a dust destructor in the immediate vicinity. Besides they could not keep the machinery and building so smart and tidy as they could if the dust destructor was half a mile away.—The ex-Mayor said Mr. Hammond had stated in committee that the combination of dust destructor and electric light works would mean a saving of £250 per annum. Would the presence of a dust destructor be any danger, or did Mr. Hammond object to it simply because without it the works could be kept cleaner?—Mr. Hammond replied that at Shoreditch the dust considerably interfered with the machinery. The works there were ill designed, and if he were asked to draw up a scheme of combination he should take care that the dust destructor portion was entirely closed up from the electricity works, instead of being connected by windows and doors as at Shoreditch. Of course, he would rather not run the risk of having his smart machinery interfered with, but still he believed those difficulties might be got over, and the saving undoubtedly would be what had been stated.—Mr. C. G. Clark asked if there was any possibility of the dust interfering or damaging the machinery providing the works were properly constructed.—Mr. Hammond replied that an engineer liked to speak from experience, and he must say that the nearest approach to the works not being interfered with was at Cheltenham. There the destructor was separated from the electricity works by a promenade. They had plenty of room there, more than they wanted to take in Gloucester. He knew of no place where a certain amount of dust did not come in. When he recommended the combination he had, of course, considered the *pros* and *cons*, and if they had it they must put up with the disadvantage of some amount of dust, and that would require greater care in cleaning the machinery, because there was nothing so dangerous to electric plant as dust. At Shoreditch some of the machinery was disabled from that cause, but as to whether he could keep it out he would be able to tell them better when he had erected the Gloucester works.

Mr. Clutterbuck, Chairman of the Committee, withdrew the recommendation that the old gasworks site be purchased, after hearing Mr. Hammond's wish to further investigate the question.

The Mayor stated it was useless to discuss the matter further at present. A special meeting of the Council could be called when Mr. Hammond had completed his further investigations.

THE LEYTON DESTRUCTORS.

In last week's "Notes" we briefly alluded to the public inspection of the Leyton sludge and dust destructors, erected at the sewage works by the Beaman and Deas Syndicate, of London and Warrington. In this issue we deal in another place with the general aspects of the destructor question, and here we will just quote sufficient from a paper read by Mr. Liversedge, engineer and director of the syndicate, before the Gloucester Engineering Society on the 18th ult., to enable our readers to understand the construction of the Beaman and Deas plant.

"In the Beaman and Deas destructor each cell of a pair acts alternately as a fume cremator to the other; when the one cell is comparatively green the gases from the other are at their hottest, and with ordinary refuse a minimum temperature of 2,000° F. is maintained in the common combustion chamber where the gases unite, provided only that a reasonable supply of refuse be maintained. It is difficult in working this destructor to avoid one or the other of the pair of cells being in a sufficiently vigorous state of combustion to completely consume, by the gases it throws into the fume combustion chamber, anything whatever of an objectionable character which may happen to be proceeding from its companion. The Beaman and Deas destructor is avowedly, purposely, and openly a quick combustion and high temperature furnace. I submit to you a brick recently, at my request, cut out of the crown of a Beaman and Deas cell which has now been at work for four years, burning rarely less than 15 tons of refuse per day, working continuously day and night for every working day, but allowed to cool down at the end of every week during the whole of that period. It is almost impossible to say by measurement whether the brick has really undergone any wear at all. What happens in this cell appears to be this. As soon as combustion is commenced, particles of siliceous matter, at a very high temperature, are projected against and adhere to the brickwork of the cell. They enter to a certain extent into combination with the material of the bricks, but in doing so they at once form a coating on the surface of the brick, which effectually stops any further action of a corrosive nature. That is to say, there is formed upon the bricks what would doubtless become with a little higher temperature a fine protective enamel, though it actually presents itself as a kind of coke. In practice this crude enamel grows so much more or less in the form of tentacles, that it is necessary from time to time to remove it. It fulfils in my opinion two other useful purposes—it helps to prevent the escape of particles of half charred paper, and assists to mix the gases arising from the drying hearth with those from the fire proper. I submit to you some pieces of this 'enamel.' The temperature by which this effect is produced is necessarily high, doubtless over 3,000° F. The quantity of house refuse which may be effectually destroyed in a pair of Beaman and Deas cells, has been demonstrated to be over 50 tons per day of 24 hours. The normal duty for which the standard pair of cells is supplied is 30 tons, though this amount is often enough exceeded. You will naturally wish to know by what means so large a quantity of refuse can be treated in one of these cells and such high temperature regularly attained. The explanation lies partly in the fact that the combustion is aided by forced draught supplied by fans."

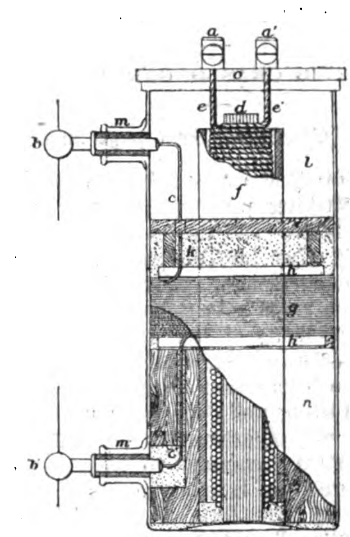
A NEW INDUCTION COIL.

Since the discovery of the Röntgen rays induction coils have acquired a much greater importance. Ruhmkorff's is still the only one in common use. The defects of this coil may be summarised as follows: low efficiency, which hardly amounts to 20 per cent.; high cost of construction both on account of the great weight and cost of the materials employed, and the labour required to wind the enormous length of secondary wire; the delicacy of the apparatus, which is easily damaged by perforation of the insulator or burning of the secondary wire; the great weight of the apparatus which renders transport difficult.

M. De Rochefort-Lucay has studied this question with M. Wydts, and finds that most of these defects are due to imperfect insulation of the secondary wire.*

At the high tensions which are generated in the coil, and which amount, often to as much as 400,000 volts, solid insulators such as glass are in the course of time, very much modified in their molecular constitution, so that in the end they usually break down. In liquid insulators a kind of electric convection takes place.

Viscous or pasty insulators, however, which have neither the porosity of solids, nor the molecular mobility of liquids, offer great advantages. Such insulators are generally hydro-carbons, which decompose slowly under the action of internal electric forces, depositing particles of carbon in suspension which, to a certain extent, reduce the insulating



properties of the material. MM. Rochefort and Wydts have been able, by a special arrangement, to use a viscous insulator without permitting the deposition of carbon.

In their coil, fig. 1, the primary coil is the same as in the ordinary Ruhmkorff coil. It consists of a core of soft iron, *d*, about which a double layer of thick copper wire, *e e'*, which ends at the two terminals, *a* and *a'*, of the external circuit supplying the current. The primary coil, *f*, is surrounded by an insulating tube.

The secondary coil consists of a single bobbin, *g*, containing 600 grammes of copper wire, 0·16 mm. in diameter.

This secondary bobbin is placed round the centre of the primary, and rests upon two tubes of glass, *h'*, supported by a block of wood. A stopper of wood, *i*, furnished with two brackets, rests on the secondary bobbin, from which, however, it is separated by two tubes of glass, *h'*.

The two ends of the secondary wire are connected to the two secondary terminals, *b b'*, in the stoppers of two necks, *m m'*, of the glass vessel in which the whole coil is contained.

The glass vessel is filled with the pasty hydro-carbon insulator.

The apparatus, thus constructed, gives sparks of 20 to 22 cm. in length, with 6 volts and 3·3 amperes (about 20 watts) applied to the primary circuit.

The primary circuit of a Rhumkorff coil giving the same length of spark, would consist of 50 to 60 flat bobbins

* Société des Ingenieurs Civils de France, November 5th, 1897.

coupled in series and separated by partitions of solid insulator. The weight of the secondary wire would be 5 to 6 kg. The number of watts required to work such a coil would be about 120.

In the new apparatus the strength of the current is greater than in the Ruhmkorff, on account of the lower resistance of the secondary. This is a very important characteristic for the production of Röntgen rays, since the time of exposure of a photographic plate necessary in any given case is inversely proportional to the strength of the current used to excite the tube.

There is nothing special about the condenser or the interrupter used in the primary circuit. Those which have been found most suitable for the Ruhmkorff coil are employed with the new apparatus.

MM. Rochefort and Wydts have shown their coil at work in comparison with a Ruhmkorff, before the Société des Ingenieurs Civils de France. The tension obtained was about double that of the Ruhmkorff, and the remarkable density of the spark showed that the strength of the current in the secondary must have been very high.

THE TELEGRAPH TROUBLES.

The Clerks' Point of View.

By CHAS. H. GARLAND.

(*Continued from page* 96.)

More than a century ago Adam Smith wrote in his "Wealth of Nations" a striking passage upon the nature of wages. "The wages of labour are the encouragement of industry, which, like every other human quality, improves in proportion to the encouragement it receives." Although it is only recently that such views have triumphed over the time-worn doctrine of the economy of low wages, the trend of modern thought and modern industrial progress is more and more in the direction of a recognition of the economy of high wages. "If you want a thing well done you must expect to pay for it" is a popular way of expressing the traditional belief in the efficacy of good treatment to ensure good work. All the best authority in labour matters leans towards the view expressed by Mr. John A. Hobson in his work on "Modern Capitalism." "Every rise in wages, leisure, and in general standard of comfort, will increase the efficiency of labour." Without pushing this view to the point of absurdity, it is easily demonstrable that a well paid contented body of servants is the source of the highest efficiency, and turns out the largest quantity of work. Towards obtaining such a body of servants it is surely the duty of administrative officers in large public departments to strive. The value of willing, efficient work cannot be over-rated in a service so important as the telegraph service. Unless the highest speed and the utmost accuracy are assured the main object of a telegram is lost sight of. The greatest value can be extracted from the expensive trunk lines by placing willing, efficient operators at either end.

When so much depends on the goodwill of the men it is surely to the advantage of the Department—to place it on no higher basis—to secure that goodwill. Yet we find a tendency rather to parsimony, and irritating refusal to listen to all appeals against anomalies. In a matter that so nearly affects the daily life of the men as the supply of their refreshments, complaints seem powerless to produce an effect upon the red-tapish system, and meals have to be taken under conditions which are a source of constant annoyance and indignation. Yet an inexpensive measure of reform would remove the ill-feeling. So with pay and prospects, whatever may be the view of the administrative officers, to the clerks it seems as though always the least generous view is taken of all schemes and scales in the matter of interpretation, and King Red Tape sits enthroned upon a mountain of anomalies with ears quite deaf to all the clamours for sympathy.

The history of the £190 maximum is an illustration of this attitude. Prior to 1881, the scales of pay for telegraph clerks were as follows:—

Senior telegraphists...	...	£140 by £5 to £160
1st class " ...	...	£100 " £5 " £160
2nd class " ...	...	£70 " £5 " £90
3rd class " ...	...	12s., 14s., 16s., a week, then £45 by £5 to £65 per year.

Complaints of "stagnation of promotion and inadequacy of pay" led Mr. Fawcett, who was Postmaster-General at the time, to make a full investigation of the matter and he found these complaints to be justified. He recommended to the Treasury a scale which was subsequently adopted and which abolished some of the classes and left the pay as follows:—

Senior telegraphists...	...	£150 by £8 to £190
1st class " ...	...	£110 " £6 " £140
2nd class " ...	...	12s., 14s., 16s., a week, then £45 by £5 to £100 a year.

This revision came into operation in 1881, and it will be seen that the most important change was the raising of the maximum from £160 to £190. This was the improvement which was to meet the "inadequacy of pay." It must also be noted that the whole of the scale was a scale for telegraphists, that is, for operators. No special qualifications were demanded for promotion to the Senior Class, men were advanced into it in the ordinary course as telegraph operators and no one doubted that if he arrived at the maximum of the first class with a good character he would pass automatically into the Senior Class. Long waits at the maxima of the classes, now so common, were not then known. Mr. H. C. Fisher, C.M.G., the Controller of the Central Telegraph Office, who was then, and is now, the chief officer who deals with the advancement of clerks, in a memorandum dated January 10th, 1896, and published as an appendix to the "Minutes of Evidence taken by the Committee on Post Office Establishments," said "Ordinary manipulative ability, combined with regular attendance and good conduct were considered sufficient qualifications for promotion to the Senior Class." This statement of the Controller is important, because it clearly demonstrates the point upon which the whole controversy hinges. Was the whole scale up to £190 a scale for telegraph operators in Mr. Fawcett's intention? As soon as the scheme was applied, and during Mr. Fawcett's administration, it was so regarded. Everybody, clerks and administrative officers alike, believed it to be so. From 1881 to 1892 the scale was so applied by officers who were familiar with Mr. Fawcett and presumably knew and carried out his intentions. Concerning this scale Mr. Fawcett said, in writing to the Treasury, "The rates of pay which I propose are not more than sufficient to afford just and reasonable remuneration to those on whose efficiency and contented service so much of the interests and the convenience of the community depend."

So we had a scale of pay established for telegraph clerks which led, with no great obstacles intervening, from 12s. per week by a slow progress to £190 per year. In a memorandum attached to the papers issued by the Civil Service Commissioners to intending candidates for the post of telegraphist, it was stated that the scale of pay offered "a prospect of obtaining £190." This memorandum was issued with the authorisation of the Postmaster-General. Surely one would have thought that with such a weight of authority and practice behind it, the "prospect of £190" for telegraphists was sufficiently secure. But in 1892 a change came over the scene. Mr. Raikes had previously, by an obvious slip of the tongue, described the Senior Class of Telegraphists as a "moribund class," and had sedulously denied having said it. Suddenly, and without notice, a special qualification was demanded over and above "manipulative ability" for promotion to the Senior Class. A technical examination requiring considerable study in leisure time was set and made, not qualifying, but in a limited degree competitive. At the same time the trend of departmental utterances was to the effect that the Senior Class was a "superior appointment," requiring special qualifications. And in 1894, in a Return prepared for Mr. Provand, M.P., we find them wrested from the place which they had hitherto so honourably filled among the "general body" in all official returns. Now they were treated and classed as "supervisors." So at last the Senior Class as a class of telegraphists had passed the moribund stage, and from its ashes has sprung, phœnix-like, a new class of supervisors who performed no supervising duties. Protests and petitions were useless. It was represented that to ask of a man well advanced in years and well up in all the duties he was required to perform, to set about theoretical study in order to secure promotion, was a terrible and unjustifiable hardship. Throughout the Tweedmouth Commission's sittings the protest was pressed, but to no purpose, and £160 per year, which Mr. Fawcett had found inadequate in 1881, was declared to be a sufficient reward for the duties of a telegraphist.

Simultaneously with this change in the definition of the Senior Class, an alteration occurred in the ratio it bore to the general body. As a class of telegraphists it had maintained a relation of 1 to about 7·5 to the classes below. But upon the new definition the basis of calculation was altered and the ratio became and has been maintained at about 1 to 10·5. The following table will illustrate the alteration of ratio :—

Date.	No. of seniors.	No. of 1st and 2nd Class.	Proportion of general staff to each senior appointment.
1881	126	966	7·66
1886	161	1,224	6 60
1888	175	1,321	7·54
1890	219	1,590	7·26
1892	170	1,740	10 23
1897	172	1,870	10 87

It will thus be seen that quite apart from the difficulty of the technical examination there was, and is, a lesser chance of advancement to the Senior Class than existed from 1881 to 1892.

The fight against the change in the Senior Class appellation, qualifications and duties was waged throughout last year, and at last, at the conference between the Postmaster-General (the Duke of Norfolk), Mr. Hanbury (Secretary to the Treasury) and a number of M.P.'s, which was held in August, 1897, at the House of Commons, I was able, with the aid of Sir Albert Rollitt, M.P., to argue the matter upon the basis of a "breach of contract." This was the sole basis then taken up. As a result the technical examination was abolished, but the words in which this act of reparation was couched are instructive and typical, "The Postmaster-General and Mr. Hanbury are struck with the consideration that it (the technical examination) may in certain cases operate to bar the advancement of an officer who—though in other respects a skilled operator and efficient servant of the department—may not possess the requisite technical knowledge required for an examination on purely technical subjects. They have therefore decided to abolish this rule, &c., &c."—*Post Office Circular*, *No.* 1,216, *August* 10*th*, 1897.

So the technical examination was abolished, but the proportion of seniors to the lower classes is still less than before 1892.

With the fall of the technical examination, our contention that the scale to £190 was an operators' scale was in effect conceded. What is now our position on the matter? This is not the place to discuss the admitted evils of classification. Suffice it to say that we had contended before the Tweedmouth Committee for the abolition of classification, on the ground that it was a system full of evils, and this contention had been admitted by the Committee, in its report, to be justified. Sir S. Walpole was one of the five members of that committee. The words of the report run thus :—

"*Promotion and Classification.*—The complaints under this head are threefold. (*a*) The uncertainty and stagnation of promotion within the classes into which the rank and file of the various grades of Post Office servants are divided. (*b*) The slowness and uncertainty of promotion from these classes to the supervising classes; and (*c*) the delay in filling up vacancies.

"We think that on entering the service it is most desirable that a man should be under no uncertainty as to his future career and prospects of promotion. While the present system of classification prevails, the realisation of this ideal must be difficult. For instance, the sorting or telegraph staff consists, as a rule, of so many second class sorters, or sorting clerks, and telegraphists. The duties of the two classes are largely similar, and in those duties many members of each class are equally proficient; yet it is only as vacancies occur in the first class that there is a chance of promotion for men in the second.

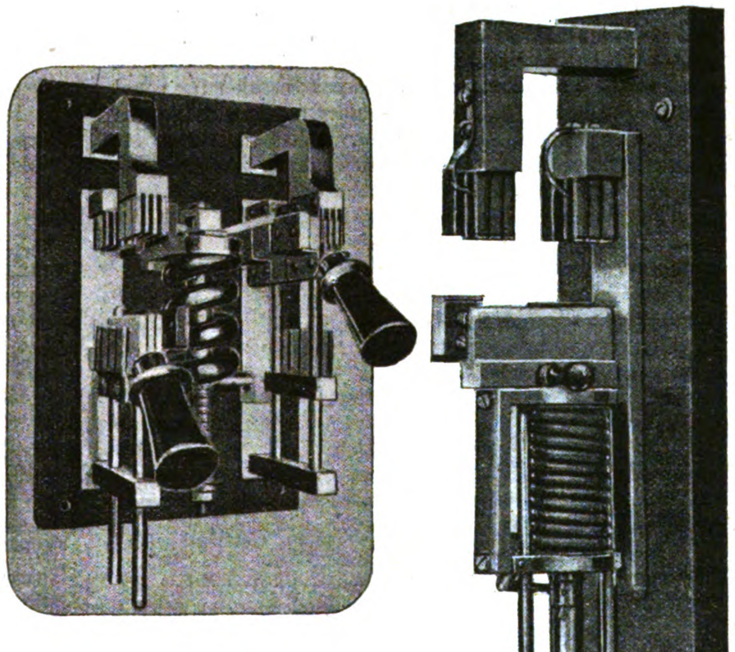
"We therefore recommend that wherever in the case of officers not performing work of supervision such classification exists, it should be abolished, and the officers under certain conditions hereafter to be specified when we deal with the cases of particular classes, should proceed by annual increments from the minimum wage of their class to its maximum."

Telegraph clerks, then, claim that the scale of their class is from a minimum of 12s. weekly to a maximum of £190 per year; that the scale was so intended by Mr. Fawcett, that it was so administered by his officers, and that the demand for any other qualifications than those of manipulative ability and good conduct have been proved to be a violation of their vested rights in this scale. All the evils of classification which led to its condemnation by Lord Tweedmouth's Committee exist in the retained classification now in force, and they demand its abolition. Unless this is done the actual maximum obtainable is only £160, a sum adjudged inadequate by Mr. Fawcett in 1881, and a sum which, under the changed conditions of to-day, is ridiculously insufficient. The prospect of a telegraphist obtaining £190 is less than it was 16 years ago, and so my contention is justified that during a period of progress a large section of public servants have slipped back and have now a lower prospect than in 1881.

(*To be continued.*)

IDEAL CIRCUIT BREAKER.*

A NOVEL circuit breaker has been put on the market by the Ideal Electric Corporation, of New York, the apparatus differing somewhat from anything yet offered to the public. The movements of the blades, or contact bars, are in a



FIGS. 1 AND 3.

* New York *Electrical World.*

vertical position, having a reciprocating motion up and down.

The illustration (fig. 1) shows a circuit breaker of the double-pole type, each pole working independently of the other, so that if an overload or short circuit should occur, both blades drop simultaneously. After closing one side of the switch, if the overload or short circuit still exists, in attempting to close the other side, the side already closed will instantly and automatically open. By this arrangement it is practically impossible to close the circuit breaker as long as an abnormal amount of current is passing. The most commanding feature of this switch is that at no time during the entire action of opening or closing, does any part protrude more than 6 inches from the face of the switchboard, thereby avoiding the danger of striking the operator, and very often injuring him. A man of ordinary strength can with rapidity and ease close circuit breakers of this type up to 5,000 amperes capacity. All conducting parts are made of hard-drawn copper, and all parts not made of copper are heavily copper plated, the entire switch being highly polished and lacquered.

The switch is self-contained and can be easily mounted on the switchboard, no lining up being necessary.

Fig. 2 shows the template and all the drilling necessary for

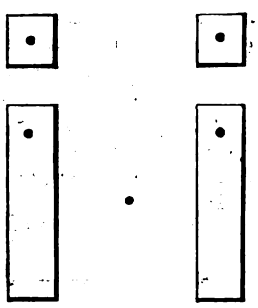


Fig. 2.

a 500-ampere breaker. In the operation of other circuit breakers two large compression springs are commonly used, but in the Ideal there is only one small one, gravity doing the rest. These breakers are also provided with an evenly divided scale, and can be adjusted from 40 per cent. to 50 per cent. overload.

Fig. 3 shows a self-contained single-pole breaker for panel and switchboard work. Only three holes need be drilled in the switchboard to mount the breaker. With the Ideal independent circuit breaker no auxiliary switch is necessary, on account of its independent action.

NEW PATENTS.

[*Compiled expressly for this journal by* W. P. Thompson & Co., *Electrical Patent Agents*, 322, *High Holborn, London, W.C., to whom all inquiries should be addressed.*]

1,258. "An improved cord grip ceiling rose for electrical work." F. W. Heaton and H. Smith. Dated January 17th.

1,290. "Means for augmenting lifting-power by electricity." H. Wolff and W. Brase. Dated January 17th. (*Complete.*)

1,294. "An improved coin-operated telephone instrument for public call." F. J. Clendinnen and G. A. P. Weymouth. Dated January 27th. (*Complete.*)

1,301. "Electric signalling apparatus." F. B. Herzog. Dated January 17th. (*Complete.*)

1,303. "Improvements in magnetic ore separators." G. J. Cream. Dated January 17th.

1,379. "Improvements in electrical insulating conduits and in the method of and apparatus for making same." P. M. Justice. (The Lithosite Manufacturing Company, United States.) Dated January 18th. (*Complete.*)

1,380. "Improvements in the regulation of dynamo-electric machines and motors." F. A. Johnson. Dated January 18th. (*Complete.*)

1,557. "Improved clockwork-operated mechanism for switching electrical current." A. S. Scull. Dated January 20th.

1,564. "Electric striking mechanism for clocks and the like." H. Whidbourne. Dated January 20th.

1,628. "Improvements in and relating to secondary batteries." W. A. Crowdus. Dated January 20th.

1,678. "Improvements in, and connected with, dynamos and electric motors." F. O. Prince. Dated January 21st.

1,686. "Improvements in secondary batteries and in means for combining electric lamps therewith." W. A. Crowdus. Dated January 21st.

1,687. "Improvements in electric signalling apparatus." S. P. Thompson. Dated January 21st.

1,691. "Improvements in electric switches." J. G. Dixon. Dated January 21st.

1,697. "Apparatus for the electrolytic treatment of bleaching liquids." M. Haas. Dated January 21st. (*Complete.*)

1,702. "Improvements in electric batteries." M. Reynard. Dated January 21st.

1,706. "Code telegraphing and circuit-testing apparatus for fire-alarm and other purposes." R. Pearson. Dated January 21st.

1,742. "Improvements in, and relating to, electro-magnetic engines or motors." C. McCallum. Dated January 22nd.

1,787. "Improvements in tools and appliances for bonding the rails of electrical railways, tramways, and the like." P. U. Askham and R. Herd. Dated January 22nd.

1,803. "Improvements in, and relating to, electric arc lamps." L. B. Codd and J. A. Codd. Dated January 22nd.

1,809. "Automatic time switch." E. A. Claremont (c/o Messrs. F. H. Royce & Co., Limited). Dated January 22nd.

1,826. "Improvements in rheostats." H. B. Cutter. Dated January 22nd. (*Complete.*)

1,828. "Improvements relating to the transmission of drawings, hand-writing, and the like by telegraph and telephone." J. Walter. Dated January 22nd.

ELECTRICAL PATENTS OF 1884, EXPIRING IN FEBRUARY, 1898.

We are informed by Messrs. W. P. Thompson & Co. that about 95 applications for electrical patents were filed in the month of February, 1884. Of these some were never completed, and those that were only three have been maintained to run their full length of term, viz., 14 years, and being of some interest we give short abstracts of them below:—

2,858. "Improvements in means for producing and utilising electric currents in secondary circuits." L. Gaulard. Dated February 6th, 1884. The induction coils consist of a round or flat primary conductor surrounded by a number of conductors connected in parallel forming the secondary conductor. The compound conductor thus formed is wound upon a bobbin which may have an iron core. The secondary coils may be grouped in various ways by suitable switches according to the requirements of the system. 5 claims.

3,034. "An improvement in apparatus for electrically controlling railway signals." C. Hodgson. Dated February 9th, 1884. Relates to electrically controlled railway signals and consists of interposing between a signal and its motor, a sway beam or its equivalent, one end of which is worked by the motor, the middle of which is connected to the signal, and the other end of which is either held stationary or is left free as determined by an electro-magnet excited by a current transmitted or brought into action from a distance. 2 claims.

4,025. "Improvements in the manufacture of electrical conductors for telephonic or other purposes." E. T. Trueman. Dated February 27th, 1884. Two or more wires are wound spirally round a hard core (of insulated wire, hemp, India-rubber, &c.). The whole is then passed through a gutta-percha covering machine. The core or the wires of the core may be first taped with insulating tape. After leaving the machine the cable may be passed into water containing plumbago finely powdered, which impregnates the surface forming a double surface. 4 claims.

THE

ELECTRICAL REVIEW.

VOL. XLII. FEBRUARY 11, 1898. No. 1,055.

CONTENTS:

THE ELECTRICAL REVIEW.

Published every FRIDAY, Price 4d.

The Oldest Weekly Electrical Paper. Established 1872.

TO BE OBTAINED BY ORDER FROM ANY NEWSAGENT IN TOWN OR COUNTRY.

OFFICE:—4 LUDGATE HILL, LONDON.

Telegraphic Address: "AGEEKAY, LONDON." Code A B C.

Telephone No. 988 Holborn.

ALL Letters should be addressed to the Proprietors, H. Alabaster, Gatehouse & Co.

ADVERTISEMENT RATES ON APPLICATION.

The "Electrical Review" is the recognised medium of the Electrical Trades.

SUBSCRIPTION RATES.—In *Great Britain*, Post Free per Year, 19s. 6d. To *all other countries*, per Year, £1 4s.

BINDING.—Subscribers' numbers bound, including case, for 4s. each volume.

CASES.—Cloth Cases for Binding can be had, price 2s. 6d. each.

READING CASES, to hold from One to Twenty-six Numbers until the Volume is complete for Binding, can now be had from the Publishers, Price 6s. or Free by Post (in Great Britain), 6s. 6d.

FOREIGN AGENTS.—*New York:* D. VAN NOSTRAND, 23, Murray Street. *Paris:* VEUVE J. BOYVEAU, 22, Rue de la Banque. *Berlin:* ASHER & Co., 5, Unter den Linden.

Cheques and Postal Orders (on Chief Office, London) to be made payable to Mr. H. ALABASTER, 4 Ludgate Hill E.C.

THE RELATIONS BETWEEN CUSTOMER, ENGINEER, AND MANUFACTURER.

THE above is the title of a recent paper presented before the New York Electrical Society by Mr. S. W. Greene. There is some sound sense in this paper. We read that "many consulting engineers, especially those who have recently commenced practice, seem to think that it is improper for them to consult with the manufacturer, or to examine his plant or to ask him for information or advice." The inevitable result is, that specifications often contain provisions which are a source of annoyance and expense to the manufacturer and purchaser alike, and which have no compensating advantages from either the engineering or the commercial standpoint. "Some of the provisions are impossible or impracticable, and the contractor has the awkward task of asking for this modification." These remarks apply to all trades, and to none more than to trades of special character. There are many contractors who, if they pay proper attention to their business, must inevitably become the best experts, and if they be also engineers, it is difficult for any outside consulting engineer to draw up a specification that will meet the views of the experts, unless the consulting engineer has taken the trouble to first place himself in communication with them.

Some of the worst faults in the drawing up of a specification with the form of tender and schedule of prices, are the adherence to old and abandoned methods, the specifying of materials, to make which or obtain from foundries, &c., will require more time than is given for the completion of the contract, whereas better goods of modern commercial sizes are, perhaps, to be had direct from stock for less money. Then the schedule of prices is often drawn up in what is evidently absolute ignorance of the conditions and necessities of carrying out work, and as a fixed printed form is insisted upon, the contractor cannot place his corrections upon it, and the result is, that what should be a good job proves to be dear and bad. We might take the majority of specifications issued within rifle shot of Westminster Hall, and none of them would pass the judgment of a sound practical builder, contractor, engine manufacturer, or other experienced man in each particular kind of work specified. Now all this is decidedly unfair to purchasers. Why should a man who wishes to have certain work done for him pay a 5 per cent. commission to some engineer to specify things which will cost 50 per cent. more, and be twice as difficult to repair as the plant that he could have bought direct from some good firm of contractors. It is because there are shoddy firms that consulting engineers are needful as go betweens, but this is no reason for the too prevailing egotism that disfigures so much of our English work. Mr. Greene finds the same to prevail largely in America, where special apparatus or methods are called for to the exclusion of standard apparatus of equal efficiency. His idea of the consulting engineer is, that his place is to see that his client selects the best system, and purchases good materials, and the engineer's business is to see he gets them, and he should, therefore, consult with manufacturers, should visit their establishments, and keep himself up to their practice. This, he thinks, no manufacturer would refuse. We should think manufacturers would be glad to keep engineers posted up in view of the chance of having to fill the specifications of these same men at any time, and there is now no mystery in manufacturing that need demand closed doors. On the question of standardising, there is too little done in England. Many things are standardised in America, and great benefit results, especially in railway work. English engineers are perhaps too desirous of making some special mark. Thus, if a railway has worked for years on certain patterns of locomotives, and is working as economically as any other railway, is it not a gross injustice to all concerned that a new locomotive superintendent should hastily alter everything, so as to be able to put his mark on the engines until the rolling stock has as many patterns as there have been superintendents? There must be progress, but a large amount of specified work we constantly meet has not even the merit of being a step forward. It is too often a step backwards into methods properly abandoned by better informed men. Naturally, in the early days of the electrical industry, the types of apparatus have been legion, but then we had not got out of the area of experimentation. Yet there are men in practice who will get up a drawing and a specification for a 20-H.P. steam engine, or for a Lancashire boiler, about which he knows less than the office boy in the boiler-maker's works. Our author points out that some specifications not only specify the conditions of service, the apparatus required, and the tests which will be applied, all which is quite proper, but they specify how the contractor shall make it, which is another.

We all know that he is right. Only a few days ago we saw some general work specified for, which went so far as to specify and show a drawing of certain plummer blocks which were inferior to what any manufacturer of shafting and mill-gearing specialties supplies in his ordinary run of standard work at half the cost these particular new designs would involve.

Many consulting engineers seem to think they ought to supply designs for their clients throughout. Never was a greater mistake made. It is their business to avoid this as much as possible, because the fewer the drawings the cheaper the cost—standard articles being purchased. It is unfortunate there should be so much payment of engineers by commission on cost. The better the engineer does his duty the less he is paid by that system, which we have heard more than once stated to be responsible for the outlay of thousands of pounds where hundreds would suffice. Manufacturers are themselves responsible for much evil. Pick up a manufacturer's catalogues, and how much information will they afford?

Take the above-named item for plummer blocks, and there is found the diameter of the bore and the price, but not a figure as to the length of bearing, the bolt centres, sole length, or breadth, or height of centre. The catalogue is useless, as compared with a German book before us, which gives every detail, so that, by its aid, a scheme of machinery becomes merely the suitable arrangement of certain standards. The truth is, we are to-day, in the commonest articles of engineers' use, in much the same condition as we were before Whitworth standardised the screw thread. The only difference is the screw thread. Everything else is much as it was. English manufacturers ought to look to this. They pay far too little attention to either standardising, as between each other, or making their own goods interchangeable. Pipe makers are grievous sinners in this respect, and of all people, they ought to follow standard sizes and interchangeableness. It is the same with makers of rolled girders, who again fall lamentably behind the American mills, in not providing suitable catalogues, with weights and all other properties of their sections.

Finally, the powers taken by engineers in their specifications to harass contractors ought to be more limited. Every contractor knows the constant trouble which arises, no matter how good his work, because of some busybody of an underling who is continually finding fault and hindering progress, too often for the sake of really spoiling what he is professing to improve. When the engineer is devoid of practical knowledge he is sure to take the part of his man, who is, perhaps, acting as clerk of works, against the word of the more experienced contractor, who is, of course, tainted because he is supposed to be making money out of his work, and must be prevented doing so at all costs.

We take it that the principal duty of a consulting engineer is, or should be, to use a practical knowledge, acquired in a contractor's works, in advising his non-technical client what to purchase from contractors. In the end, it is the contractors who make and employ their own special experts to design. Can a consulting engineer get out plans from steam boilers to incandescent lamps that can compare in any one item with the work of the dozen engineer experts who devote themselves the one to boilers, the other to engines, the third to the dynamo, and so on? Yet this is what we seem to find is the motive underlying most specifications. The system cannot even be claimed good for trade, for it runs up expense and chokes off progress, and the engineer himself is worse off, for he gets his commission probably on a single job costing, say £2,000, where otherwise he might have drawn on two or more jobs at £1,500 each, had an easier time of it, and given better satisfaction.

A Difficulty in Electric Traction.—If one pair of wheels in an electric locomotive combined in series should happen, from any cause, to slip, its high speed of rotation will set up so much counter E.M.F. that the current will be checked and torque reduced, and this will happen to every wheel in a series combination. Coupling rods to check the tendency of one wheel to slip are undesirable additions to an electric as to any other locomotive. As series working is very usual at times of starting, a single greasy spot on the rail might destroy the tractive force of the whole machine. One of the most promising systems of control is stated by the *Electrical World* to be the Leonard system, using separately excited motors with fully-saturated fields in starting, and with armatures supplied from a motor generator with adjustable secondary voltage. If, then, any one wheel slips its torque will be reduced and slipping will stop, but the remainder of the wheels will be unaffected, and as electrical locomotives are not overweighted for tractive purposes, the additional mechanism will be an advantage than otherwise. For yard purposes the electrical locomotive is extolled. It can be run into sheds without risk of dirt, smoke, or fire. It is also quieter and not so alarming to horses.

EXPERIMENTS ON INDUCTION AT LONG DISTANCES WITH HIGH FREQUENCY CURRENTS.

In an article in the *Electrical World*, N.Y., by Messrs. Northrup, Pierce and Reichmann, a series of experiments are described in which several novel instruments and methods were made use of.

The receiver employed was a kind of galvanometer for high frequency currents, and indicated approximately the maximum value of the current in the receiving circuit by the deflection of a copper disc suspended by a quartz fibre inside a coil. The copper or silver disc is set at an angle of 45° to the plane of the coil, and when an alternating current is sent through the latter, currents are induced in the disc which tend to twist it into the plane of the coil.

Considering the importance which the study of high frequency currents has recently acquired, some details as to the construction of this detector may be worth giving, and we therefore quote the description given by the authors:

"The delicacy of these instruments was due to the use of fine quartz fibres for suspension, and rapid damping was obtained by placing the disc between the poles of a permanent magnet. Any motion of the disc generated currents in it which brought it back to rest. Some details regarding the construction of these instruments are worthy of note, since care and experience in these details can alone make the instrument delicate and serviceable. The deflections were read by means of a telescope and scale. The complete period of the first instrument was 16 seconds, and that of the second was 13½ seconds. In the first instrument the system consisted of a ring of pure silver, with an external diameter of 12 mm. and an internal diameter of 7 mm., mounted upon a fine glass rod, which carried a thin, small mirror just above the coil. In the second instrument a silver disc 6 mm. in diameter was used instead of a ring. The mirror in this instrument was 4 mm. × 7 mm. Such mirrors can readily be made by silvering ordinary microscopic cover glass. They may be given the desired shape by breaking them in the following manner: The mirror is laid face down upon a hard smooth surface; the edge of a steel rule is placed upon the silvered surface and pressure exerted, when the mirror breaks along the edge of the rule. Since cover glass is extremely thin, using varnish upon the back of the mirror, or mounting it directly with any kind of cement, will distort the glass and give a confused image of the scale. The mounting is best accomplished by first fastening with hot sealing wax a small strip of cover glass to the rod. The surface of this should then be touched with shellac, and the extreme upper edge only of the mirror laid upon it. The greater portion of the mirror is thus unstrained, and a clear scale can be obtained from an extremely light mirror. The coil of the instrument shown in fig. 1 was wound in several layers upon a hard rubber bobbin with very thin walls. Waxed paper was placed between the layers, and the whole coil was soaked in hot beeswax and rosin. This precaution is required to prevent short circuits between the layers. At the top of the coil all the wires made a semi-circular turn, so as to leave a slot in one side of the coil, through which the glass rod bearing the silver ring could pass, thus bringing the axis of rotation of the ring in the centre of the coil. This made the coils detachable. Various coils with different numbers of turns were tried. One which gave satisfactory results, when the frequency of the induced current was comparatively low, contained 104 turns of No. 36 B. & S. wire. The axial depth of the coil may be as great as, but not greater than, the axial distance from one edge to the other of the silver ring or disc, when placed in the coil at an angle of 45°. The ends of the quartz fibre were attached with hot sealing wax.

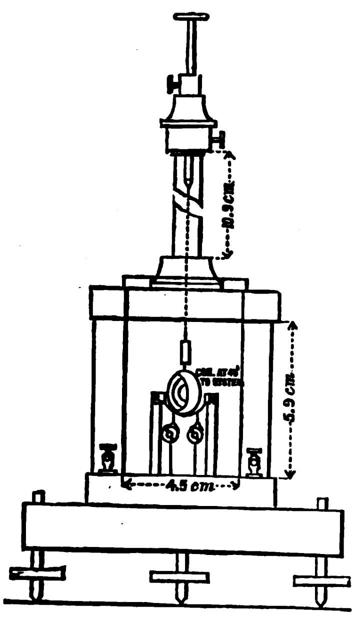

Fig. 1.

"It is essential that the silver ring should not come in contact with iron, for since the ring is suspended between the poles of a magnet the attraction upon the ring due to the presence of iron may greatly decrease the sensitiveness of the instrument. On the other hand, the silver may be found dia-magnetic, in which case the system, when brought by the torsion of the fibre into the right position, may be found to be unstable. This difficulty may be overcome by brushing the silver disc with a weak solution of iron sulphate. A few trials will serve to nullify the action of the magnet on the system."

Using this indicating instrument, the authors made a number of experiments to show the importance of resonance in the two circuits between which the electric waves are being transmitted. In one series of experiments, the inducing circuit A, fig. 2, consisted of a rectangular loop of bell wire, the dimensions of which could be varied. A condenser, *a*, of small and variable capacity, and a spark gap, *b*, were inserted in series in the loop. The receiving circuit, B, consisted of a similar loop with a condenser and the indicating instrument in series. The condensers in both circuits were built up of tinfoil and glass plates 18 × 20 inches. Fractional values of the capacity of one pair of plates were obtained by folding back the upper tinfoil sheet a known amount. The spark gap consisted of two brass balls, about 2 cm. in diameter, their separation being effected by means of a micrometer screw.

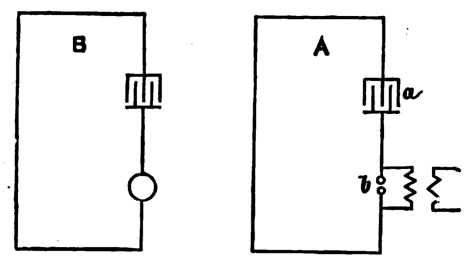

Fig. 2.

In experiments on the production of electric waves, it is important that energy should be supplied to the radiator continuously during the period when the indicating instrument in the receiving instrument is deflecting. Since an induction coil or an influence machine supplies energy only for a time, which is short compared with the intervals between each discharge, it is evident that the maximum amount of radiation cannot be obtained by the use of such sources of current. To obtain the best effects a source of current should be employed which will give a continuous discharge across the spark gap. It is further necessary, in order that oscillations may occur in the circuit, that the discharge across the spark gap should not be of the nature of an arc.

The following simple and effective method of generating a continuous stream of high frequency currents was employed by the authors. The E.M.F. of the alternating 100-volt city circuit was raised to the required amount by means of a high potential transformer. The terminals of the secondary were directly connected to the opposite sides of the spark gap, *b*, fig. 2, and the primary to the city circuit terminals, through a variable inductive resistance. Arcing was prevented at the spark gap by a strong blast of air supplied by a foot bellows. Without this air blast to blow out the arc only very feeble oscillations occur, and practically no induction effects could be obtained; but, with it the oscillations are strong and continuous. It is unnecessary with this arrangement to keep the balls bright and polished. Moreover, the effects obtained can be made extremely uniform if we insert in series with the secondary of the coil a condenser of such capacity that the arc between the balls ceases to have a flaming character.

The experiments with the above described apparatus verified, in a very striking and simple manner, the importance of resonance and high frequency in the effective transmission of inductive effects. The authors deduce by an elaborate mathematical investigation, a formula for the deflection of their high frequency galvanometer. This formula is somewhat complicated and contains many factors. It indicates that the deflection is inversely proportional to the sixth power of the distance between the radiator and receiver, so that this style of apparatus is not very suitable for wireless telegraphy to long distances. Indeed, the authors estimate that signals could not be transmitted over a greater distance than 1,600 feet with the best arrangements of their wire loop apparatus. These experiments are, however, of considerable scientific interest, and the methods described of generating and detecting electrical oscillations appear to possess some novelty, and to have considerable practical value.

COMPARATIVE COST OF STEAM AND ELECTRIC POWER.

II.

THOUGH perhaps less convenient than electric transmission, mechanical methods may, if well designed, be more economical where the load factor throughout the year is high. But a large class of power users make such variable demands for power that the ratio of average to maximum is very small. Such conditions favour electricity both as a power transmitter and as a prime mover in that particular place. Illustrative of the first case is taken an engine of 1,000 H.P., delivering 750 H.P. to machinery and 250 H.P. to power transmitters. But if the load factor be 35 per cent. only—not a specially small factor—the useful work will be only 28·6 per cent. But electrical transmission would give the same total efficiency of 75 per cent. from engine pulley to machinery, and for a load factor of 35 per cent. the total efficiency would be 50 to 60 per cent., or double that for mechanical transmission. Thus, while the total power would be the same and the 1,000 H.P. engine would be retained, coal would be saved to the extent of 30 to 40 per cent., which with coal at 12s. would mean £400 to £600 per year in a non-condensing plant.

In particular cases the main plant could be reduced by at least a fourth with all that this implies of saving.

If at full load the constant charges are £1,000 a year, and the same figure stand also for the variable charges, the variable charges will remain about constant per H.P.-hour. If the load factor becomes 50 per cent., the constant charges remain the same, and the variable charges become halved.

At half a million H.P.-hours annually, the constant charges will be 1 cent per hour, and the variable charges also 1 cent. With only a quarter million H.P.-hours annually, the constant charges will become 2 cents per H.P.-hour, the variable charges being, as before, 1 cent. The total full load cost is thus 2 cents, as against 3 cents when the load factor is 50 per cent.

Hence the total costs must, for economy, be chiefly a summation of variable costs. Constant charges on plant become higher, out of all proportion, as steam engines become smaller. This is a well recognised fact. One man can attend to a 200-H.P. plant. In smaller shops either one man must attend to the small boiler and engine of 2 H.P., or they must be left to anyone, and there is an enormous but not directly visible waste. Central station working has the advantage of a better average load than any individual consumer, but there is the disadvantage of the costly system of mains, and these have proved fatal to central station power distribution, except for small consumers who have been willing to pay as high as 20 cents per H.P. hour. This, of course, applies to steam distribution. Electricity steps in here, and proves capable of transmitting power economically to scattered consumers, and this apart from its higher efficiency for distribution. Much of this arises from the ability of distributing two energies over one main, viz., lighting energy and power energy, both generated by the same machinery. As in a large station the variable charges are small on all loads which do not "peak," a small charge for power brings in a handsome return. With special bids thus possible for consumers of electrical power, it would seem impossible for small isolated steam powers to compete with electrical. This is Mr. Taylor's conclusion, and it should be the province of our English companies to look for customers among the small shops. We have some knowledge of the power consumed by small shops, and we are convinced there is a huge opening. We are also convinced that makers of small motors should lay themselves out to answer a few plain questions as to cost and power. At present the fashion seems to be to tell nothing. Surely there has by this time accumulated sufficient data as to the use of current by a lathe, a drill, or a fan to enable a rough estimate to be given.

The power absorption by machinery has always been a little known subject, but this is largely because the absorption by the machine has been complicated by the question of shafting. With electricity, it would be so very easy to know just how much a 9-inch lathe consumes idle, or cutting, that we wonder no one who has the opportunity has found this out and made a list of a few sizes of tools and their various power absorption. Such a table would, we feel sure, greatly facilitate business.

(*To be continued.*)

SOME NOTES ON SINGLE-PHASE MOTORS.

BY A. C. EBORALL.

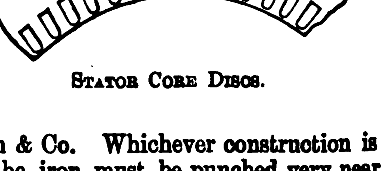
(*Continued from page* 137.)

The Stator.—The stator of modern motors is always built up of lightly insulated soft iron core discs, these, as shown in fig. 7 (A, B, C), being either slotted, or pierced with rectangular or semi-rectangular holes for the reception of the windings. Fig. 7A is Messrs. Brown, Boveri & Co.'s construction, fig. 7B that of the Oerlikon Company, and fig. 7C that of

FIG. 7A.

FIG. 7B.

FIG. 7C.



STATOR CORE DISCS.

Messrs. Kolben & Co. Whichever construction is used, the apertures in the iron must be punched very near the inner edge, or else there may be considerable leakage across the small iron bridges or air-gap. In practice, the distance of the hole from the internal periphery of the stator is rarely more than 3 millimetres in the largest motors, and is a mere shred of iron in the small ones. If the stator is of large size, the core discs are punched out in sections, these sections being afterwards bolted up together, the joints in one layer being covered up by the next.

The depth of the hole or slot varies in practice from $1\frac{1}{2}$ to 3 times its width; it should be as small as possible, as leakage increases with the depth of winding. The distance between each hole or slot is a little more than the width, there being preferably many small slots or holes rather than fewer large ones, as these would tend to destroy the evenness of the field, and might cause heating of the rotor.

The advantages of thus imbedding the windings (first introduced by Mr. C. E. L. Brown) are several. For example, the weight output is increased, the magnetic resistance is reduced to a minimum (and hence a smaller magnetising current is required, and larger power factor results), and all eddy currents in the stator windings are prevented. Further, if the motor windings are also embedded, as in practice is the case, the air-gap need only be large enough to give the necessary mechanical clearance, the strain comes on the iron, not on the windings, and both rotor and stator are smooth all round.

As to which is the better, the hole or slot, probably, taking them all round, there is not much to choose between them. The pole produced by hole winding is more even than that produced by slots, but owing to the absence of the small iron bridges, there is probably a little less leakage with the latter. Messrs. Kolben's semi-rectangular hole has more winding space than either of the other two, and gives a very even pole.

The next thing to consider is the winding. The speed of the motor, and the frequency of supply being known, the number of poles is given by

$$p = \frac{120 \times \text{frequency}}{\text{revolutions per minute}}$$

as already pointed out. They may be produced by either a ring or drum winding; but some form of the latter is invariably used, and is far the best. Ring winding has several disadvantages—its magnetic leakage is greater; it requires more wire for the same effect, and, moreover, precludes the use of an iron case for holding up the stator core discs on account of the leakage that would be produced through it. The bad effect of leakage on the starting and power factor of a single-phaser have already been pointed out.

Fig. 8 shows diagrammatically the form of drum winding introduced by Messrs. Brown, Boveri & Co., and now

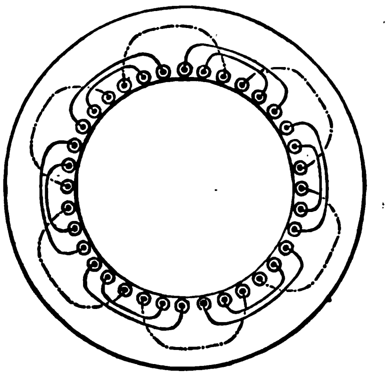


Fig. 8.—Stator Drum Winding.

invariably used on the Continent for all kinds of induction motors. The dotted lines indicate the starting winding. In practice, each coil of the working winding is wound quite straight, its shape being a simple rectangle, while the coils of the starting winding are bent up and over the others. It is usual to wind about two-thirds of the holes with the coils of the working winding, the starting winding consisting of equal ampere-turns of thinner wire, as it is only in use for a short time. The number of turns on the starting winding depends, however, on the nature of the starting device employed, as will be seen later.

The Rotor.—Rotors for single-phase motors may be of two kinds: a simple short-circuited bar winding, or a three-phase bar winding, whose ends are joined to slip-rings on the shaft and between which may be inserted resistances, used as a rule only during the starting of the motor, and whose function will be discussed later.

If the rotor is of the first form, it is built up of core discs of the shape shown in fig. 9A, each stamping being lightly insu-

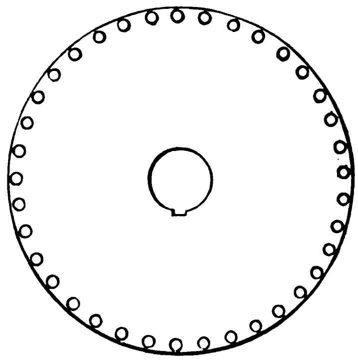

Fig. 9A.—Rotor Core Disc.

lated from its neighbour, and the two end plates being made considerably stouter than the rest for the sake of stiffening the rotor. Three or more bolts are generally passed through from end to end, and parallel to the shaft, for the same purpose. Through the holes in the core discs copper bars are passed through, the bars being insulated by paper or other material from the iron. The copper bars are short-circuited at each end by means of copper rings, the section of these rings, for a reason presently to be explained, being considerably less than the total section of the bars.

The reason for insulating the rotor bars at all is simply to fulfil one of the conditions previously enumerated as to confining the rotor currents to proper paths. The reason

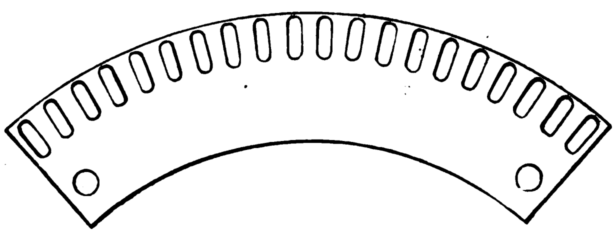

Fig. 9B.—Rotor Core Disc.

for using rings for short-circuiting the bars is partly because they offer a good cooling surface, and partly because by their use over-wrapping at the ends and the use of connectors is avoided, the whole forming a sound mechanical job.

If the rotor has to be of the second form mentioned above, with its windings connected to slip-rings, its construction is somewhat different. As such a rotor is generally of large size, the core discs are built up in sections, as shown in fig. 9B, and owing to the fact that the centre of the iron part of large rotors is inactive, these sections are built up either on a spider, or else on the rim of a fly-wheel, according to the size of the motor.

The number of holes or tunnels is determined by reference to those in the stator, they being always more numerous than those in the latter, and an uneven multiple of them when possible. It follows from this that the rotor holes or tunnels will be longer and narrower than those in the stator.

(*To be continued.*)

LEGAL.

Salmony & Co. v. Improved Electric Glow Lamp Company.

The hearing of the case, the verdict in which was briefly recorded in our last issue, was resumed on Monday last week.

Mr. Max Salmony was cross-examined at considerable length by Mr. Rufus Isaacs, but on the whole bore out his counsel's opening statement as to the agreement arrived at with the defendant company.

Mr. Ernest Rosenberg, also a member of the firm, called by Mr. Tindal Atkinson, gave evidence. He said that at the interview of September 16th, 1887, the defendants accepted their conditions, and an agreement was completed. Mr. Snell, the solicitor, and Mr. Fanta wanted them to guarantee that Mr. Brown, of Eastbourne, and Mr. McLeod, of Glasgow, would accept an assignment of their agencies, but they refused to give it. The invoices were returned by the defendants, but they ultimately agreed to take the goods.

Mr. Rubenstein said there was a discussion as to the £700 alleged profit from the agencies, at a meeting at the Hotel Metropole, but no guarantee, such as was suggested, was given. There was only an offer from Mr. McLeod, but no acceptance of any contract.

His Lordship said the questions seemed to be whether the defendants were entitled to rely on the special agreement which they set up, and to damages because the arrangement with McLeod was not a contract, but only an offer.

Mr. Rufus Isaacs said he would reserve his remarks on behalf of the defendants, and at once call witnesses.

Mr. Ferdinand Fanta said he was managing director of the defendant company, and was also manager of the syndicate before it was transferred to the company. At the interview of March 30th, 1897, when he gave the order for the lamps, he wanted them for the Jubilee. They were to be delivered by May 25th. It was a condition that the lampholders were to be delivered within 8 or 10 days. It was absolutely essential to have the goods some time before the Jubilee, June 3rd or 4th, when they were delivered was not in sufficient time. They were able accidentally to use some of them—some 2,200. He gave instructions to the employés to refuse to take delivery after May 25th, but they were delivered in the absence of the warehouseman. He met Mr. Salmony and Mr. Rosenberg about June 7th or 8th, and told them the goods were useless. As it happened, he was able to use some of them in connection with the illumination of St. James's Street, and plaintiffs agreed that he should do his best to dispose of part of them. He promised to do so. He did what he could, and there was no dispute about the price of those which he used. He never agreed to take the whole of them at the invoice prices. The remainder of the goods in respect of which he had not paid into Court were still on his premises, and could not be used. Plaintiffs told him they would hand over the contracts with Brown and McLeod, which showed £800 or £900 profit, but eventually £700 was agreed upon. He then believed he was getting the contract with McLeod, and the profit, but the company never got a farthing; as a matter of fact, Brown's contract was still in abeyance.

Mr. Tindal Atkinson: What is your complaint with regard to this matter of McLeod's?—Paying £300 for certain contracts, which were represented to us to show £700 profit. We found that no business resulted from it. There was no contract, no sale of anything.

Were you in a position to supply the lamps?—Certainly.

When were you first informed that it was only an offer from McLeod, and that there was no contract?—I found it out when McLeod refused to allow their letters and orders to be assigned to the company without his consent. The syndicate was formed to purchase certain patents and the sale of the lamps in the United Kingdom.

By His Lordship: They expected to get Schwaber's agency.

In further cross-examination, Witness said he thought he had been deceived in the matter of the contracts with McLeod and Brown. The syndicate was formed for the purpose of purchasing certain patents, Schwarber's amongst them. In order to successfully carry out his plans it was necessary that he should obtain the sole agency, which was then in the hands of the plaintiffs, and he had to purchase them out. That was not the principal object he had in view with regard to his agreement with the plaintiffs. In that particular negotiation the principal consideration was that witness would undertake to take delivery of all lamps which Messrs. Salmony might have, not only on their premises but which they might have on their premises six weeks after that date, and it turned out that those amounted to some 10,000 lamps which had been invoiced to them, and which the syndicate agreed to purchase for a higher price than the plaintiffs had paid for them. Witness stated that he never agreed to take the holders in dispute, but would try to dispose of them, acting as the plaintiffs' agents in fact. Witness told Mr. Salmony that if he did succeed in disposing of them, he should require a commission. He did not know that there was any representation as to the commission in the company's books. When the plaintiffs sent the company the invoices, they were returned to them, but re-returned by the plaintiffs to the company. Witness ordered the holders in question for the purpose of using them at the Brussels Exhibition. He told Mr. Salmony that they would not be any use to him unless he could use them for Jubilee Day, and then send them on to Brussels. Witness would have to decide about the Brussels contract in May. Not getting the holders delivered in time, he could not get the contract. As a matter of fact, he did not press for that contract, and it was not accepted.

Mr. Herbert Thompson, book-keeper of the defendant company, gave evidence, generally bearing out that of Mr. Fanta. This evidence closed the defendants' case.

Mr. Rufus Isaacs said the whole question was what was agreed upon between the parties. As to the 25 per cent. commission on the £100, though large, it was not, he contended, exceptional, under the circumstances. Having gone over the correspondence, he contended that the story told by his clients was the most probable one. Under the deed of assignment of the two contracts of McLeod and Brown for £300, he maintained that defendants were entitled to damages for breach of contract. It was said that the counter-claim was a bogus one, and only concocted for the purposes of that case; but nothing could be further from the truth than that assertion, and on that counter claim he was clearly entitled to damages.

Mr. Tindal Atkinson maintained that the counter-claim had been manufactured for the purposes of that trial, and complained that the want of pleadings in the case had materially lengthened the proceedings—a remark with which his Lordship concurred. Plaintiffs denied that they had guaranteed the contracts. The fact was, that McLeod had refused to homologate, and defendants took the risk of that when they made the agreement. He submitted that plaintiffs were entitled to judgment on both the claim and counter-claim.

His Lordship gave judgment on Tuesday morning. Having briefly gone over the evidence, he said there was no question in his mind that the contract with Mr. Brown, of Eastbourne, was an actual contract, and that the transaction with Mr. McLeod, of Glasgow, was one which might fairly be described as a contract in view. It was a contract in view and not in hand, although there was very little difference between them. Proceeding to deal with the counter-claim of the defendants, he said that if it was found that if a document or agreement had missed conveying what it was intended to convey, it was right and just that the document should be reframed for the purpose of getting at what both sides intended and what was meant. He had no doubt that at the time the agreement was made both the parties understood one thing only, and that was that the benefit of the correspondence and arrangement with Mr. McLeod was to be transferred, whatever it was worth. The defendants had the full benefit of the objection they took, but they did not communicate with McLeod, or try to verify what had been said with regard to him for fully two months. In fact, no question was ever raised until nearly a year later, in any serious form. Not until October 22nd did he find any serious complaint, McLeod had then refused to homologate and to transfer his contracts, and it was only after that that the liquidator of the syndicate, Mr. Bartlett, wrote and drew attention to the fact that the contracts with McLeod and Brown had not resulted in the business and profit which plaintiffs had guaranteed, and that Messrs. McLeod and Brown had repudiated the right of the plaintiffs to hand the contracts over to the syndicate. He repeated that there had never been any proper negotiations with McLeod, and that no claim was made with regard to him for nearly a year. The defendants' solicitors' letters were sufficient to show that what was intended and understood to be given was given and accepted on the terms of the guarantee which was written. He did not see why he should give the defendants damages on the counter-claim, because McLeod had declined to trade with them as the persons to whom his contract with another person had been handed over. Defendants took their risk of that. A. could not assign to B. a contract with C. against the latter's will. The defendants took the risk of McLeod agreeing to the assignment, and McLeod declined. He could not, therefore, give defendants damages on the counter-claim. With regard to the claim, the matter stood thus: In March, 1897, a contract was made for the sale of these goods, which had to be manufactured in Germany and supplied to the present defendants. It was said they were not supplied in a reasonable time, but reasonableness of time must depend upon the circumstances, such as the time necessary to give the orders, to construct the articles, and to bring them to England. It must be a time reasonable to the vendor as well as the purchaser. If April 14th was agreed upon, the order could not have been carried out. When the order was carried out, the defendants contended that delivery was too late, and sent back the invoices, but they afterwards took them back, and did, upon some terms which were not disputed, agree to take and pay for the goods. Therefore the question arose, on what terms and in what fashion did they take them as agents, or did they, when they found they could use a certain number, during the Jubilee, take them? The same could not be said as to the lamps, which were said to have been required for Brussels, as their tender there was refused. There was no sufficient weight of evidence to justify him in saying that any special agreement was come to. There was no trace in the books of any correspondence as to any such agreement, and no form of accounts was kept on that basis. In the face of the conflict of evidence, he must be guided by the letters which passed. It appeared to him that there was no proof that the goods should not be paid for, as they were ultimately accepted, taken into the stores, and used by the defendants. He therefore gave judgment for plaintiffs on the counter-claim and also on the claim, with costs. On the application of Mr. Tindal Atkinson, he made an order for the money paid into Court to be paid out.

The House-to-House Electric Light Supply Company.

A petition for the reduction of the capital of this company was sanctioned by Mr. Justice Romer on Saturday. The company was formed in 1888 with an original capital of £350,000, which had been reduced to £200,000. Amongst the shares issued by the company were 100 founders' shares, which it was desired to get rid of, and the general scheme of the petition was that the founders' shares should be surrendered to the company, and that the holders should subscribe for a certain number of ordinary and preference shares which were part of the original capital of the company, leaving the capital at £199,500 instead of £200,000.

Brown v. I. E. S. Accumulator Company.

This case came before Mr. Justice Romer, on Saturday, on motion for judgment as a short cause in default of defence. This company was incorporated in 1895 for the purpose of carrying on business as manufacturers of electrical batteries, and the plaintiff was the holder of debentures in respect of which the company made default. A company named New & Mayne were also made defendants, they being interested in the taking of the accounts. Mr. Justice Romer made the usual order in a debenture holder's action.

CORRESPONDENCE.

Wireless Telegraphy—A Forecast.

When reading the paragraphs appearing now and again in the lay newspaper, recording a further advancing step towards the solution of the problem of telegraphing without the aid of wires, how many are there who realise the possibilities—the certainties, it can be safely said—meant by its accomplishment? Very few, as few probably as foresaw the results of the experiments of Cooke and Wheatstone, 50 years ago, in telegraphing with wires. The adoption and practical application of the new discovery will, however, be probably far more prompt and decisive than those referred to of half a century back; indeed, it would be hard to find a more significant index of the progress made in that short length of time, than in contrasting the eager readiness with which a new invention is now taken up, with the indifferent treatment it then met. For instance, the big London dailies, probably the most liberal and eager of all concerns in availing themselves of any new thing to their advantage, were about the slowest to see the wonderful possibilities—and, to us, evident gain—of telegraphy. Reuter—a specialist even in pre-telegraphic times, in the rapid transmission of news by means of carrier pigeons—one of the first to realise the full meaning of the new discovery, and to utilise it, failed, month after month, in inducing any of the London papers to accept his reports; and even had, ultimately, to supply a month's reports free, that comparison might be made between them, and those of the "special correspondents" of the existing order, to see if his own were true and reliable. The *Daily Telegraph*, to its credit, was the first to accept the new order of things, being, of course, soon followed, in self-defence, by the others; the *Times* coming, with a due and fitting sense of weight and dignity, at the tail end of the procession.

Telegraphing without the aid of wires is already practicable, granted favourable conditions, at distances up to 20 or 30 miles, and as this is simply the thin end of the wedge, when that wedge shall have been driven home, as in due course it must be, to its full length, by the time the butt end is out of sight, telegraphing from one end of the country to the other will be possible. It requires but little imagination to combine the telephone with the new departure; and we will thus have practicable the power of talking in London as readily to a friend, say, in Edinburgh or Dublin, as though he were sitting the other side of the table. Electric energy having by then also become a household requirement, supplied by each municipality, stored, much as coal now is, in a cellar, and fulfilling in an infinitely more ready and cleanly manner all the present purposes of coal—with a host of others to boot, from rocking a cradle and working a sewing machine, to turning the mangle and closing the front gate—there will be everywhere available a ready margin for telephonic use.

Given this necessary first power, the only other thing needful will be suitable transmitting and receiving instruments, in which will be arranged the essentials to success, of ready adaptation to varying distances and directions, and a means of conveying the particular message to the particular receiver in the hands, or at the ear, of the one it is wished to communicate with. But let an instance be taken of probable use to illustrate the point, a traveller, say, wishes to despatch an order to his wholesale house—he would, of course, be himself unnecessary were it not for the necessity of showing samples of his goods. In his room in the hotel he takes out of its case his small portable transmitter, and attaches it by the stud at the end of a short length of wire to the slot in the wall, connected with the electric reservoir and wires in the basement. By the help of a small attached compass and a map, he next turns the revolving body of the instrument upon its stand until an indicator points exactly in the true direction of the receiver, and then sets a second indicating pin, after consulting a table of distances, to the figure representing his distance from head-quarters. There being little danger of his message getting mixed up amongst the thousands of others travelling in the upper air, as each one will take its own distinct path, like rays of light and heat, the only point now remaining is to arrange that the message will be delivered at the right receiving instrument. This will possibly be accomplished by the setting of some combination of letters and figures arranged beforehand by the two correspondents—in much the same way that a safe can only be opened by one who knows the word, or combination of figures the lock has been set to. These simple preliminaries over, the order is sent away by merely speaking against a vulcanite disc—so many yards of material to so-and-so, or so many tubs of butter to somebody else.

It looks a bit strange at first to us; but would not the prophecy of the possibility of sending a message from London to New York, under the sea, in a few seconds, have seemed equally strange, or stranger, to our fathers? Yet this is a commonplace of to-day; telephonic communication between the two centres is also, probably, on the point of being made possible, so there is, after all, but the thin substance of one wire between what is, practically, accomplished, and that which we regard as so strange.

And what a difference it will make both in the smaller and ordinary, as well as the larger and extraordinary, affairs of life! The smaller possibilities of commerce have been touched upon, but we can go much further afield, and anticipate totally different conditions to present ones, for the markets of the world. The American, Russian or Indian wheat grower will be closely and cheaply in touch, by individual word of mouth, with his English broker; the cotton grower with the Manchester weaver; the iron master with those on the spot selected for the placing of his rails and machinery. The fisherman at sea, with his latitude and longitude accurately worked out, will be able to send his Grimsby or Yarmouth buyer full particulars of the fish in the hold of the trawler under his charge; whilst the mariner in general, in the same easy and ready manner, will have it in his power to gratify his love and sentiment, by chatting with his wife and children ashore whenever he has the mind to.

Travellers, again, in distant lands, if they wish—which, in view of the inevitable book, they probably will not—will, at least, have the means of communicating items of their journeyings to friends at home, as it will simply mean the carriage of a battery on the head of an additional porter, or on the back of an extra mule. The Polar expedition of the future, too, instead of trusting to the evident insecurity and frailty of pigeons as news bearers, will be able to speak with the interested ones of the country they belong to—and order off the usual relief expedition at the exact time, and to the exact spot necessary.

In short, as will easily be seen, this one small point gained and the country will be changed in every respect, socially, commercially, and economically; and Signor Marconi, if not the discoverer, in popular estimation certainly the applier of the new style of thing, deserves his statue of bronze if any pioneer of progress ever did, whether the statue, considering the extra pace and nervous strain involved, will remain a well washed and honoured one, is another matter altogether.

J. Rees.

The Electric Arc.

I have been much interested in the renewed speculations with regard to the electric arc that American research seems to have given rise to, and with others have been somewhat amused at their methods. Some of M. Blondel's latest methods seem also to merit some criticism. It is against the laws of Newton that he should be able to detect a counter E.M.F. even $\frac{1}{800}$th of a second after breaking the current (1) because no storage action has been detected in the arc, and if such action did go on it would involve a difference between the striking E.M.F. and the constant E.M.F.

(2) Supposing the counter E.M.F. to persist for a certain time after the impressed E.M.F. has been withdrawn. Let it persist (*a*) for a definite time, say, $\frac{1}{n}$th second. Then, if in the alternating arc we increase the alternations, the resistance due to counter E.M.F. diminishes till at n ~ per second the counter E.M.F. is zero, which is absurd—as we used to say in Euclid.

(*b*) If the counter E.M.F. persists for a certain fraction of the time of impressed E.M.F., this would make peaky E.M.F. curves still more peaky, and would introduce a new harmonic in the curve, suppositions contrary to fact, as the flattening of peaky curves in the arc shows.

I have, therefore, the following hypothesis to offer for the action of the arc, founded on observations and experiments carried on for some time at the electricity station here (at Prospect Hill Waterworks), and I do so before these observations have been completely concluded, in the hope that some "mightier pen" may turn his attention to this aspect of the arc. Let us take the case of the arc between carbon electrodes. Carbon is a tetravalent element at ordinary temperatures, but we know little or nothing of its behaviour at very high temperatures, for instance, that of the arc. It struck me that it was not only possible but probable, that the carbon molecule became dissociated, forming two molecules, each divalent; the tetravalent molecule may be assumed for theoretical considerations to be a compound (of two divalent molecules) which we may term carbide of carbon. This dissociation takes place at the surface of the positive carbon and is a percentage dissociation, a phenomenon not unknown in chemistry. Now, if this be the actual state of affairs the formulæ for electrolytic action should hold good, because, although the second stage of the reactions is different, the first is the same. On this assumption, the electrolyte is carbide of carbon, the ion divalent carbon, whose chemical equivalent is therefore 6. Now,

$$\text{W} = \text{C T } \epsilon$$
$$= \text{current} \times \text{time} \times \text{electro-chemical equivalent.}$$

If C = 10 amperes, T = one second, $\epsilon = \cdot 000010384 \times 6$ we have

$$\text{W} = 10 \times 1 \times \cdot 000010384 \times 6$$
$$= \cdot 00062304 \text{ gramme dissociated per second.}$$

$$\cdot 00062304 \,\underline{)\, 1\cdot}$$
$$1{,}605 \text{ seconds to dissociate one gramme.}$$

Now for the arc under consideration the watts were 400,

$$\overset{\text{Secs.}}{\therefore 1{,}605} \times \overset{\text{Watts.}}{400} \times \overset{\text{Cals. in one watt.}}{\cdot 24} = 154{,}080 \text{ calories.}$$

Again, $10^8 \text{ E} = 10\, \epsilon \text{ H J}$, where E = volts, H = calories, J Joules equivalent,

$$\therefore 10^8 \text{ E} = \cdot 000010384 \times 6 \times 10 \times 154{,}080 \times 42 \times 10^6$$
$$= 40\cdot 316171344 \text{ volts.}$$

This was almost exactly the volts between the terminals of the arc.

Iron was now taken for electrodes, and the same observations carried out. The chemical equivalent of divalent iron is 27·95.

The watts consumed were, on the average, 270.

Taking the two formulæ as before,

$$(1)\ \text{W} = \text{C T } \epsilon. \qquad \text{C} = 10 \text{ amperes, T} = \text{one second.}$$
$$= 10 \times 1 \times \cdot 000010384 \times 27\cdot 95$$
$$= \cdot 00029035 \text{ gramme per second dissociated}$$

$$\cdot 00029035 \,\underline{)\, 1\cdot}$$
$$= 344 \text{ seconds to dissociate one gramme.}$$

$$(2)\ 10^8 \text{ E} = 10\, \epsilon \text{ H J},$$

and $270 \text{ watts} \times 344 \text{ secs.} \times \cdot 24 = 22{,}291\cdot 2$ calories.

$$\therefore 10^8 \text{ E} = 10 \times \cdot 00029035 \times 22{,}291 \times 42 \times 10^6.$$
$$\therefore \text{E} = 27\cdot 182805770 \text{ volts.}$$

This represents the calculated voltage of the iron arc. The iron is tetravalent and is dissociated, the tetravalent molecule becoming two divalent molecules. As before then we may assume an electrolyte "ferrous ferride," and the volts thus calculated are exactly those observed.

Returning to the physical aspect of the arc, it seems to me that the current on arriving at the end of the positive carbon dissociates a certain percentage of the carbon molecules, the electrical energy being absorbed *without heat* to keep up this dissociation. This accounts for the counter E.M.F. which I assume to be the energy of chemical affinity required to keep divalent carbon in that form. But the dissociated carbon molecules at once combine with others to form tetravalent carbon and the latent energy of affinity is given off as heat, and therefore light. But not all the carbon molecules re-unite *in situ*. Some are carried across by some means (akin to ionic progression it may be) and thus form a conductor between the positive and negative carbons. The resistance of this will vary with its length and area. According to observation the amount carried across seems to be almost exactly $\frac{1}{10}$th of the amount dissociated. This led to some experiments on enclosed arcs, the results of which are somewhat interesting, especially with regard to the duration of the carbons. These results together with the calculations for arcs with various electrodes, especially monovalent elements, and photos of arcs taken with special reference to the foregoing hypothesis, I hope to lay before the readers of the ELECTRICAL REVIEW, firstly, if the editors will give their kind permission, and secondly, if no "bolts from the blue" are hurled at my pet theory and bring it with a crash about my ears.

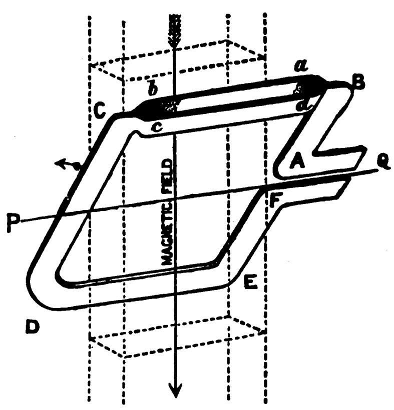
Walter D. Jamieson.

Shielded Conductors.

Mr. Price is evidently trying to get at the truth with regard to eddy currents in buried armature conductors, and I will not deny that he may be very near it; but he made a mistake when he selected one or two of the most carefully worded statements from my letter (which appeared in your issue of January 28th), and used them as a foundation upon which to build a number of misleading and altogether erroneous deductions.

I do not wish to hurt Mr. Price's feelings, and he must not conclude that he has "again incurred my contempt," when I say that, in my own mind, I am quite convinced of his having once more "missed the point." One of the sentences quoted—the one of which I am more particularly proud—is as follows:—"Surely we are right in assuming that, *for a given E.M.F. generated*," (yes, in the main dynamo circuit if you like, or in the path of the eddies if you prefer it), "the eddy current loss in a conductor depends upon the *time* which it takes in passing into or out of the uniform magnetic field under the poles." Of course it does! The eddy current loss depends, not only upon the amount of the eddy currents, and therefore of the E.M.Fs. producing them, but also upon the *time during which these eddy currents are flowing in the metal*; and as this line becomes shorter, the heating by eddy currents will be less, not *more*, as Mr. Price would have it.

In the hope of being able to express myself in the same language as Mr. Price, I will borrow his diagram and his formula.



He says that if N magnetic lines are threaded through the closed eddy current circuit, *a b c d*, in the time, *t*, the heat developed is proportional to $\frac{\text{N}^2}{t}$, which is quite true; but, in his endeavours to prove that my explanation conveys the opposite meaning to that which was intended, he has no right to consider N and t as independent variables. On the contrary, the whole argument is based on the assumption (printed in italics, which Mr. Price has omitted) that the E.M.F. generated $\left(\frac{\text{N}}{t}\right)$ is constant; hence $\text{N}^2 \propto t^2$, and the heat developed, is proportional to t.

Q. E. D.

[Perhaps I ought not to have taken it for granted that the E.M.F. tending to produce eddy currents bears a definite relation to the E.M.F. in the main dynamo circuit; but an inspection of Mr. Price's figure will show that the assumption is correct. A given conductor moves into, and through, a field of a given configuration at a certain speed. Let E be the E.M.F. in the compound bar, B C, as it moves through the field, and *e* the mean E.M.F. generated in the eddy current circuit, *a b c d*, as the bar enters the field. Now double the speed of the conductor, and halve the strength of field. It is quite evident that both E and *e* remain the same as before.]

Having disposed—it is hoped, successfully—of Mr. Price's criticisms, I may, perhaps, allow myself to step down, and say a word or two on his behalf. Although he did not do me justice, that is no reason why I should not deal fairly with him, especially as I am inclined to think that his point of view is the right one.

Mr. Price does not put his case clearly; but what he says amounts to this:—

Firstly, he does *not* believe in the "snapping across" of the lines as the buried conductor enters or leaves the field. On the contrary, he maintains that such a conductor will, other things being equal, take the same time in passing into or out of the uniform field under the poles as a surface conductor. (It is a pity he did not mention this at the start.)

Secondly, the uniform field in which the conductor finds itself after passing through the "fringe," is very much weaker in the case of a buried than in that of a surface conductor. To quote Mr. Price's own words, "The solution of the difficulty lies clearly in the small intensity of the maximum field, the rate of speed at which the bars enter that field being assumed to be constant." (I have slightly altered the second half of the sentence, as it is of more interest to know what Mr. Price meant to say than what he actually said). The fact that the above statement is diametrically opposed to the views which Mr. Price expressed in his article, tends only to enhance its value by clearly proving its author to be actuated by no meaner motive than a desire to get at the truth, and nothing but the truth.

In conclusion, I would advise anyone interested in the subject to go carefully through Mr. Price's letter, skipping only the one or two irrelevant paragraphs. If he will take the time and trouble to go sufficiently deeply into it, he may disinter much valuable information, which will be of use to him in after-life.

Alfred Still.

Is an Electric Traction Engine Subjected to Shocks, or is it not?

I gather from Mr. Raworth's further criticism in your issue of the 4th inst., on Dr. Emery's article, that the doctor, although, no doubt, right in intention, is wrong in contention.

Experience has shown us that it is advisable to employ a higher factor of safety in designing an engine liable to frequent, sudden, and extreme variations of load, as when driving a rolling mill or electric traction dynamo, than for an engine having a constant and regular load such as electric lighting.

In answer to the question at the head of this letter, I know of a peculiar shock to which engines not designed to do the duty they are called upon to perform, are particularly liable. Dr. Emery's experience, I can imagine, causes him to dread this shock, but Mr. Raworth appears to be in happy ignorance of it. I refer to the nasty jar occasioned by precipitation on to the "scrap heap."

I am glad Mr. Raworth no longer poses as the instructor of "young engineers," and the slayer of "dead dogs," for the former are probably competent to form opinions on elementary problems, and the "dog" of American experience and practice, judging by the ominous twinkle in his eye, is far from being killed by Mr. Raworth's frequent bladder belabourings.

I see that Mr. Raworth has now assumed the *rôle* of Pharaoh, which appears to me to be far more profitable and becoming, although it is rather late to dream the dream when the "lean kine" of American enterprise are so rapidly eating up the "fat kine" of British contracts. I can only hope that Mr. Raworth and other English manufacturers will bestir themselves, and speedily acting on the interpretation of the dream will, through their respective Josephs, gather in of the rich harvest of American knowledge before the famine is upon them.

James F. Rossiter.

Mr. Robert Hammond and Shoreditch Destructor.

I read with a huge amount of astonishment in your account of Mr. R. Hammond's opinion of the Shoreditch destructor, that several instruments or parts of our machinery have been rendered useless by reason of the dust, &c., emanating from the destructor. I can only say that no such thing has ever happened; and I certainly think Mr. Hammond should state his authority for the statement or withdraw the same as publicly as he has made it. He is entitled, of course, to his opinion as to the design or merit of the plant, but I must say his remarks do not harmonise with the voluptuous praise he bestowed upon the joint scheme and general design when he and our Gloucester friends were so courteously conducted over our works.

H. E. Kershaw,
Chairman of Electric Lighting Committee, Shoreditch Vestry.

In your last issue I notice, under the heading of "Electric Lighting and Dust Destructor for Gloucester," some comments made by Mr. Hammond, which are absolutely untrue and without the slightest foundation whatever. I refer to his statement wherein he says that some of the machinery has been disabled owing to the dust, and I now wish to state that no machinery or plant whatever has been disabled at this station, through the dust or otherwise.

And, in the interests of other Corporations having destructors under consideration, also of my staff and self, I trust that you will give publicity to this letter in your next issue.

Also, I would point out that such garbled and misleading statements, as put forward by Mr. Hammond, are but a poor return for taking the trouble to show him and his Gloucester friends over these works, when full information and particulars were given him by the Chairman of my Committee (Mr. Kershaw), and

C. Newton Russell,
Chief Electrical Engineer.

Coronet Street, Shoreditch,
February 8th, 1898.

THE ELECTRICAL ENGINEERS VOLUNTEERS.

Certain important modifications have been made in the constitution of this corps, which, we think, will tend to popularise it among engineers. We know from our own experience that a good class of men are ready to join if it is made easy for them to fraternise on terms of equality with their fellow privates. It is obvious, from the rules that have been formulated and reproduced below, that the corps will be one of high standing; that is to say, the terms of entry guarantee the rank and file being composed of men of some position in the industry. In its present form, the corps is deserving of the heartiest support, and we trust that electrical engineers will show their sympathy by enrolling themselves as members.

The following information has been issued from head-quarters:—

The head-quarters of the corps will be at 13, Victoria Street, Westminster.

The uniform will be the same as that worn by other Royal Engineer Volunteers, with such modifications as the War Office approve. Members will pay for their own uniforms; but the corps will reimburse the cost to efficient members to the extent of one-half of the Government grant they earn by their efficiency, so that after two years' efficiency the cost of the uniform will be repaid.

The corps will be armed with the Lee-Metford rifle.

The training is divided into two kinds—military and technical.

The military work consists of infantry drills, musketry, &c.

The technical work includes every application of electricity to war, with the exception of telegraphy, and such other work as will be useful to an electrician or engine driver in carrying out his duties, such as signalling, fitting, loading, priming, and connecting up submarine mines, a certain amount of boat work, and knotting, splicing, &c.

This work will be carried out partly at head-quarters, but mainly at defended ports.

In order to become efficient each member must attend a continuous training at a defended port for at least eight days each year. In addition, 78 hours' technical work must be done each year (48 after passing as "expert"). Each working day—after the first eight—of the continuous training counts as six hours; each full day counts six hours; each half day four hours. The remainder may be made up in periods of 1, 1½, 2, 2½, 3, and 3½ hours.

The capitation allowance is £5.

An allowance of 5s. is made for a whole day, 2s. 6d. for a half-day: but a "recruit" must attend 40, a "trained man" 20, an "expert" 10 hourly drills before earning these allowances. During the continuous training each member earns 5s. a day. The whole of these allowances will be devoted to the maintenance in camp and to the remuneration of efficient members.

Drills—both military and technical—will begin as soon as members are enrolled.

Intending members are requested to study the conditions of efficiency. Every effort will be made to make it easy to comply with them.

Below will be found an extract from the rules of the corps:—

5. Every enrolled member who is non-efficient in any year shall pay to the funds of the corps, on or before November 10th in that year, a sum equal to half the Government capitation allowance which he failed to earn. . . . . The commanding officer shall have power to remit payment, wholly or in part, in special cases.

8. No person shall be admitted as member or honorary member unless proposed by one or more members of the corps, and approved by the commanding officer.

24. Any member wishing to leave the corps may do so on November 2nd, providing he shall have given notice of his intention not later than the 30th of the preceding September. Failure to comply with this rule shall render him liable for half the amount of the succeeding year's capitation grant.

Intending members should write to the adjutant, Captain Brady, R.E., 13, Victoria Street, S.W., who will supply all information. They should give their full name, address, occupation, and electrical qualifications. If they wish to join as engine drivers they should state their qualifications for that work.

Every application must be accompanied by a reference to a member of the corps or to some other person well known to the commanding officer.

Before enrolment, each candidate must be passed as fit by a medical officer.

Every member shall be enrolled for three years at least. A member leaving before completing three trainings shall be liable to a penalty.

Hence a member who serves for three years, and is efficient in each year, will be put to practically no expense, as he will have incurred no penalties, and the cost of his uniform and camp expenses will have been refunded to him.

J. Hopkinson, F.R.S., Major,
Commanding the Electrical Engineers,
R.E. (Volunteers).

BUSINESS NOTICES, &c.

Agency.—We understand that the Edison and Swan United Electric Light Company, Limited, has appointed the Direct Importers, Limited, of Bulawayo, sole agents for Rhodesia.

Art Metal Work.—We understand that the business of Messrs. G. R. De Wilde & Co., carried on for the past 12 years by Mr. George Rexworthy De Wilde at 10 and 11, Archer Street, Shaftesbury Avenue, has been purchased by Messrs. Thomas Potter & Sons, and amalgamated with their own business, of ecclesiastical and art metal workers, which has been carried on since 1827 at 44, South Molton Street. Mr. De Wilde has joined Messrs. Potter & Sons, and will in future have charge of this branch of their business.

Bankruptcy Proceedings.—The *London Gazette* gives notice of the release, on January 12th, of the trustee (T. H. Stephens) in *re* Thomas Maddren (T. Maddren & Co.), electrician, of Cardiff.

A first and final dividend of 3s. 9d. in the £ has been notified under the failure of George Thompson (G. Thompson & Co.), electrical engineer, of Queen's Road, Brighton.

Brussels Exhibition Awards.—In last Friday's *London Gazette* we observe a long list of the awards made in the British Section of this Exhibition. Among the members of the Executive Committee of the British Commission, who have received awards, are the following:—*Diplomes d'Honneur* to Sir A. K. Rollit, Mr. James Dredge, C.M.G., Sir E. H. Carbutt, and *diplomes commemoratifs* to Sir F. A. Abel, Major S. Flood Page, Mr. E. Windsor Richards, Mr. Alex. Siemens. *Diplomes commemoratifs* have also been awarded to Mr. W. H. Massey, Mr. R. W. Blackwell, and Mr. Philip Dawson. Among the industrial exhibitors are the following awards: *Hors Concours* to Mr. R. W. Blackwell. *Grands Prix* to Brush Electrical Engineering Company (in participation with the Electrical Syndicate, Brussels Exhibition), Eastern Telegraph Company, Elliott Bros., Fielding and Platt (in participation with the Electrical Syndicate, Brussels Exhibition). *Diplomes d'Honneur* to Fielding and Platt, W. T. Glover, C. A. Parsons & Co., J. S. Raworth, Ruston, Proctor & Co., Tangyes, Limited. Gold medals to—Eastern Telegraph Company and Horsfall Furnace Company, Thomas Parker and Co. Silver medals to—Forced Draught Syndicate, Roller Bearings Company. Among the awards to collaborators are:—*Diplome d'Honneur* to Mr. George Elphinstone (Messrs. Elliott Bros.), and a gold medal to Mr. F. B. Behr (lightning express).

Calendars.—From the Peckham Truck Company (Mr. R. W. Blackwell, 39, Victoria Street, S.W.) we have received a calendar for the year, 1898. It is made up of very large sheets—one for each month, on each of which there appears a good photographic view of electric and cable cars, trucks, &c., supplied by this well-known company.

Messrs. King & Co., electrical engineers and contractors, Leith, also send a neat calendar.

A handy-sized and serviceable wall calendar has been brought out by Messrs. Nalder Bros. & Thompson.

Catalogues.—Mr. Harry W. Cox, of Cursitor Street, has issued a pamphlet describing and pricing various apparatus supplied by him for use in Röntgen ray research, such as induction coils, focus and vacuum tubes, screens, batteries, &c.

The Electrical Sundries' Company, of Berners Street, have issued a new and enlarged catalogue of their electrical fittings and accessories. Cut-outs, switches, fuses, wall plugs, lampholders, standards, counterweight and other hanging fittings, brackets, pendants, hall lanterns, electroliers, lamps, &c., are among the variety of electric light apparatus and fittings.

Copper.—Messrs. H. R. Merton & Co. have prepared tables showing the stocks of copper in England and France, and advised from Chili and Australia. Their statement is as follows:—

	Tons.		£	s.	d.
Jan. 31st, 1895	54,848	at	40	5	0
" 1896	46,128	"	43	17	6

Croydon Tramways Company v. The British Electrical Traction Company.—In the Appeal Court on Tuesday, the Master of the Rolls, Lord Justice Rigby, and Lord Justice Vaughan Williams, heard an appeal by the Croydon Tramways Company against a judgment of Mr. Justice Kekewich in the Chancery Division. This judgment was briefly referred to in the ELECTRICAL REVIEW for January 21st, page 79. In January, Major-General Kaye sued in the Lower Court, on behalf of himself and other ordinary shareholders in the Croydon Tramways Company, asking that the company might be restrained from carrying out an agreement for the sale by them of the undertaking and its lines to the British Electric Traction Company. After hearing counsel's arguments, Mr. Justice Kekewich granted an interim injunction restraining the directors from carrying out the agreement to sell their undertaking to the British Electric Traction Company. Mr. Cripps, Q.C., Mr. Warrington, Q.C., and Mr. Rowden appeared for the appellants; Mr. Bramwell Davis, Q.C., and Mr. Bradford for the respondents. The case was opened on behalf of the appellants, and Mr. Bramwell Davis and Mr. Bradford replied for the respondents, after which the hearing was adjourned.

When the case was resumed yesterday, the Master of the Rolls said their lordships had come to the conclusion that it would be extremely difficult to do justice in the matter in the absence of the British Electric Traction Company. He therefore thought that the appeal had better stand over in order to allow of the purchasing company being added to the motion. The case was adjourned for a fortnight.

"Isolacit."—This is the name of an insulating and acid proof material made by Messrs. Baeumcher & Co., of Dresden, who have just appointed Mr. Archibald Campbell, of 28, Gray's Inn Road, W.C., sole agent in England. It is stated to have given great satisfaction to a number of the best-known electrical manufacturers and electric railway companies, also in battery establishments, in Germany. It is produced in different mixtures, liquid, semi-liquid, and solid, and among the advantages claimed for it are the following:—It does not burn, ignite, or entirely lose its elasticity, but adheres to the movements of ductile and pliable objects without becoming brittle or cracked. It is not troublesome to use, and there are no unhealthy evaporations. It is not affected by the most acrid acids.

Lists.—Mr. C. R. Heap, 47, Victoria Street, S.W., the sole importer for the United Kingdom for the C. and C. Electric Company, of New York, sends us lists of that company's bipolar dynamos and motors. The list gives some very neat blocks of the straight and curved field types, and detailed particulars of same. The C. and C. slow speed generator is also described.

Lloyd & Lloyd v. D. & W. Henderson & Co.—Sheriff Strachan, on 31st ult., heard proof in an action at the instance of Lloyd & Lloyd, of Birmingham, holders of letters patent in the United Kingdom for the Benardos system of electric welding, against D. & W. Henderson & Co., engineers and shipbuilders. The pursuers sought to bind the defenders to an agreement which they entered into in 1892 to pay a royalty of £200 per annum for the use of the inventions comprised in the pursuers' patent. After paying royalty for two years, the defenders, it is alleged, refused to further implement the agreement, assigning as a reason, among others, that the invention could not perform the operations which it was alleged to be able to perform. Pursuers denied the defenders' allegations, and contended that the defenders, by letter, agreed to hold themselves bound by the deed and signature of Mr. Andrew Henderson. When the hearing was resumed, Mr. Bannatyne, addressing the Court for the defendants, said the first and most important question was whether or not there was a completed agreement between the parties, and the second point was, assuming there was a completed agreement, could the document be set aside on the ground of fraud and essential error. He did not mean deliberate fraud, but innocent and unintentional concealment of material alterations, amounting to fraud in a civil action. The precedents showed that, in order to have perfect obligation, there must be deliberate and voluntary consent. Defendants' case was that they were induced to sign the license sued on through concealment on the part of plaintiffs. The duration of the license was a matter of importance to defendants. They bought the plant for experimental purposes, and never contemplated the further burden of an annual payment of £200 to the end of the patents. The draft they approved of did not contemplate that, and it was amended to place the question of duration beyond doubt, if possible. If there was doubt about the meaning of the clause, apart from amendments, it must be read against plaintiffs. The Court would have to find there was no consent given by defendants to this contract. It was a Scotch contract, and must be construed by the law of Scotland. Accordingly, it should have been signed on each page by both parties before witnesses, and by all the partners of the firms. It was not a mercantile document, but it was a formal deed, and not being executed according to the formalities of signing in Scotland, the license could not be enforced in Scotland. Judgment was reserved.

Personal.—Mr. T. Scott Anderson, of Sheffield, asks us to state that his practice as a consulting engineer is being carried on as before, and is not a branch of the new firm of Scott Anderson and Beit. We understand that he has just received instructions from the District Council of Kilnhurst to survey and report upon the lighting of their district. He is further retained by the directors of new steel works in Yorkshire to report upon the complete equipment in their works of lighting, welding, and motor plants.

Private Bills.—The Examiners of Private Bills sat at the House of Commons on Monday to consider the standing order proofs of Bills lodged for consideration during the present session. There was "no appearance" registered in the case of the Folkestone Electric Tramways Bill. In the case of the Hastings and St. Leonards Tramways Bill, which had been part heard by the examiners, the petition was endorsed "no appearance on adjournment." The consideration of the Bill was further adjourned until the 21st inst. The consideration of the London United Tramways Bill and the Blackpool and Fleetwood Tramroad (Tramways Extensions) Bill was postponed.

South African Electrical News.—The *British and South African Export Gazette* has the following items:—A scheme having been mooted for lighting Kokstad, Cape Colony, with the electric light, opportunity will shortly be afforded for electric engineering firms to tender for the requisite material. Overhead wire to the extent of 47,300 feet, for the purpose of lighting Bulawayo, has been supplied to the order of the Bulawayo Waterworks and Electric Light Company. The installation of the electric light in the railway workshops at Mafeking is under the consideration of the Railway Department, and the extension of the system to the town is also mooted. In this event very considerable orders for machinery and material will shortly be placed. The two large alternating current dynamos, of 15,000 lamps capacity each, with 1,250 revolutions per minute and a voltage of 2,288, required for the electric lighting of Bulawayo, have been supplied to the Bulawayo Waterworks and Electric Light Company by the General Electric Company of New York. The completion of the equipment of the Village Main Reef gold mine only awaits the arrival of the electric plant, for some time on order, but delayed owing to the engineering strike. An order for a small dynamo, to supplement the existing electric lighting plant, has been placed by the Durban Municipality. Two automatic cut-off engines of 150 H.P. each have been supplied by Messrs. McIntosh, Seymour & Co. for the Bulawayo Waterworks and Electric Light Company.

Sunderland Exhibition.—At this Exhibition the Sunderland Forge and Engineering Company, who carried out the electric lighting of the buildings, putting in 50 arc lamps and about 30 100-C.P. and 250 16-C.P. incandescents, exhibit at their stand two inverted vertical compound double-acting enclosed self-lubricating central valve engines coupled direct to two compound-wound dynamos of the inverted two-pole pattern. They also show several ship lighting plants, and a 25-B.H.P. enclosed motor driving a joggling machine.

ELECTRIC LIGHTING NOTES.

Aberystwyth.—It is proposed, in view of having a fresh agreement with the Electric Lighting Company, to obtain their terms for the extension of the arc lighting and also for three years' incandescent lighting.

Beckenham.—The District Council has agreed to supply electricity to the district at an estimated cost of £36,000.

Bedford.—A correspondent says that the annual balance-sheet of the Bedford Liberal Club shows that by adopting the electric light a saving of £40 has been effected, for whereas electricity costs £41, with a gas bill of £5, the gas bill alone formerly amounted to a sum of £90.

Belfast.—The Electric Committee says that it cannot supply current for the Exhibition Hall, Botanic Gardens Park (as required for the year) until the new supply station is in working order. But as the parties will rest content for the present with 50 8-C.Ps., the supply is to be furnished and a main laid. The storage battery and switchboard contractors are ready to begin delivery. The central station is already partly insured in the Fine Art and General, and other companies are being negotiated with. The electrical engineer is to wait on Messrs. Harland & Wolff in reference to their application, and ascertain "what voltage they would require the electric current to be supplied at, and also to inform them that the Committee would be prepared to supply up to 1,000 Board of Trade units per annum on a maximum demand of not more than 500 H.P. at 2½d. per unit, and beyond that on the same maximum demand at 1½d. per unit, the cable to be laid to their gate."

The Board of Guardians are asking Mr. Clegg to submit an estimate of the cost of electric lighting plant, and the maintenance thereof, for the Workhouse.

Bromley.—The Bromley Urban District Council are still holding over the transfer of the Electric Lighting Order, having, in response to their inquiries, received what they consider to be a most unsatisfactory reply from the company.

Burnley.—The Council has accepted a tender (£4,888) for the supply of two combined engines coupled with dynamos for extending the electric lighting works.

Cardiff.—The electrical engineer has reported to the Lighting Committee upon the mains generally throughout the town. He suggests that the cables supplying the arc lights be replaced by others, and that the lamps be connected to them in accordance with the latest Board of Trade requirements. If this were not done, he would not be surprised at a failure of some of the lamps after any heavy wet weather.

Devonport.—The Council has appointed Prof. Kennedy to prepare an electric lighting scheme for the district.

Dorking.—The District Council has, after discussion, resolved to introduce the electric light into Dorking, and an Electric Lighting Committee has been appointed to report.

Dover.—Some of the consumers have been conferring with the Electricity Supply Company *re* the charges for current.

Dublin.—The Local Government Board having considered Mr. Cotton's report, have notified the Corporation that the £20,000 asked for will be "loaned" subject to approval of the specification and detailed estimates in connection with the new cables and works. The Corporation will therefore have financial resources so far to carry out their new scheme for an extension of the electric lighting of the streets.

Dudley.—The contract for lighting by electricity the Public Hall, for the purpose of the Industrial Exhibition, was carried out by Messrs. Webster, Michelson & Co., of Dudley. There were 4 2,000-C.P. arcs and incandescents equivalent to 500 16's. The plant employed for the purpose comprised a combined high speed vertical engine and multipolar dynamo. The same firm have a stand at the exhibition where they show various electrical fittings and several "C" type Dudley dynamos and motors.

Dundee.—Four electric lamps are to be erected in High Street, Lochee, the electric plant at the public baths supplying the current.

Durham.—At the last City Council meeting a letter was read from Edmundson's Electricity Corporation, Limited, stating that proposals had been made to them by the Dean and Chapter of Durham for putting down plant for supplying the Cathedral and College with electric light. They proposed to leave a margin for the use of private consumers, and asked the consent of the Council to mains being laid through the streets to enable them to supply intending customers. The consent asked for was granted.

Ealing.—A report is to be prepared on the subject of the proposed application of incandescent lamps to the arc lamp posts. A mechanic is to be engaged to remedy, as far as possible, the defects in the present arc lamps.

Edinburgh.—A committee of the Scottish Conservative Club report that they have entered into a contract for the re-wiring and extension of the electric light installation of the Club, as well as for the supply of electric light fittings at a total cost of £1,400. The re-wiring and fitting of the smoking and reading rooms has been completed, and the remainder of the work is to be carried out during the current year.

At the meeting of the Electric Light Committee on the 1st inst. it was reported that over 2,200 8-C.P. lamps had been applied for during the last two weeks.

Fire Station Lighting.—The L.C.C. Fire Brigade Committee has been going into the question of electric lighting for the chief fire station, with the chief officer. He suggests that the National Electric Free Wiring Company's system of wiring should be adopted, and he proposes that, instead of the necessary plant being obtained from various firms, a contract should be entered into with the company for the supply and fixing of the plant and fittings, but that some of the fixing and the making of brackets, &c., should be executed by the workshops' staff, the company reimbursing the Council the wages of the men thus employed. The company has submitted a tender amounting to £992, such sum to include the provision and fixing of an engine and dynamo, with switchboard, cables, mains, distribution boards, branch wires, switches, incandescent lamps, batteries, &c., and 14 arc lamps. The company undertakes to employ the Council's men to assist in every possible way. The Committee recommend the Council to accept the tender of the National Electric Free Wiring Company, Limited, to carry out the electric light installation at the chief station of the fire brigade for £992, less the amount of the wages of the Council's employés who will be engaged on part of the work.

Glasgow.—A member of the Corporation is to move that in view of the unsteady character of the electric light in St. Andrew's Hall, of the noises emitted by the arc lamps used, and of the fact that the roof is practically invisible under the present method of lighting, a system be adopted which will be both efficient and silent.

Greenock.—There is a suggestion that before anything further is done in connection with the electric lighting scheme, a plebiscite of the residents be taken. The Council require to notify the Board of Trade shortly whether or not they intend to apply for a provisional order, and Mr. Tighe, electrical engineer, Paisley, has been appointed to consult with the sub-committee.

Grimsby.—The Public Lighting Committee has been considering the report of the sub-committee on electric lighting. The following places were visited for the obtaining of information:—South Shields, Newcastle, Leeds, Manchester, Brighton, Shoreditch, and Westminster. The sub-committee recommended the engagement of Prof. Kennedy as consulting engineer. The sub-committee added that overtures had been made by the Tramway Company as to the supplying of energy for tramway traction, and authority was asked to negotiate with the company, and obtain a definite proposal from them. It is proposed to ask Prof. Kennedy to prepare an estimate.

Hampstead.—The Vestry has decided to apply for a loan of £40,000 from the London County Council in order to pay for some very extensive plant for electric lighting it has just added to the central station in Finchley Road. It is hoped to finish in about six weeks' time the installation of the public electric lighting from Heath Street to Chalk Farm, about a mile and a half in length.

Islington.—The Electric Lighting Committee's report just issued, of the working of the electric lighting system in Islington during the year 1897, shows that whereas in the previous year a profit on revenue account had been shown of £1,615, in 1897 the profit made was £4,432. With the repayments on capital account, the loss on the two years was reduced from £1,836 to £318 14s. 4d., and this loss might have been turned into a profit but for some delay in starting the new plant. Mr. Gay, the electrical engineer, in a note to the account, says the number of units sold in 1896 was 298,000, and this produced a revenue of £7,573. In 1897 there were 504,000 units sold, or an increase of 206,000, being equivalent to 69 per cent. In 1896, the working cost was £5,958, equivalent to nearly 4½d. per unit. In 1897, it was £7,858, an increase of £1,900, and equal to 31 per cent.; the cost per unit falling to 3⅝d., or a penny per unit less than the previous year. Thus, with an increased cost of production of 31 per cent., the out-put has increased 69 per cent., and the revenue 62 per cent. The gross profit in 1896 only amounted to 21 per cent. on the revenue, but last year it rose to 36 per cent., a very satisfactory increase. The capital account now stands at £150,850, of which £6,623 remains in hand.

The increasing demand for current here has necessitated further extensions, and £12,000 has been voted by the Vestry for purchasing and erecting the new plant, which will include two boilers, a 1,500 H.P. engine, and 1,300 kw. alternator, at a cost of £7,180. The steam and other pipes and fittings, also foundations, accumulators, boosters, and various accessories, will amount to £4,820. The Electric Lighting Committee has reported to the Vestry on the steps being taken by other local bodies regarding the payment of the trade union rate of wages.

Lambeth.—The Lighting Committee has reminded the vestry that the South London Electric Supply Corporation undertook to supply energy, free of charge, for 25 arc lamps, to be erected by the vestry in certain streets. The committee submitted a list of positions.

Lancaster.—The Electricity Committee has accepted the tender of Mr. Wm. Massey for oil, and the Scottish Asbestos Company for packing.

The Electricity Committee has increased the salary of Mr. C. E. M. Johnstone, electrical engineer, from £120 to £140 per annum.

Leeds.—At the present time part of Wellington Street, Boar Lane, and Briggate are illuminated at night by means of gas and electricity. It is intended shortly, however, to dispense with gas until midnight. At that hour the gas lamps will be lighted, and electricity switched off.

Leith.—The Special Committee on Electric Lighting has accepted the following tenders for the electric light station buildings:—Mason work, Kinnear, Moodie & Co., £7,693; joiner work, Kinnear, Moodie & Co., £934; plumber work, Patrick Knox & Sons, £269; iron work, A. Mather & Son, £1,972; glazier work, Robert Graham, £307; slater work, M'Lean & Reid, £99; plaster work, Stuart's Granolithic Stone Company, Limited, £69.

Leyton.—The Guardians having asked for terms for a supply of current for lighting all the workhouse buildings for two years, the Council has resolved to charge 3½d. per unit. A deputation from the Council is to go to Brighton to see how they charge for current there.

The resident engineer has reported as follows:—Electricity generated during December, 25,062 amperes; units sold, 15,981 amperes; number of applications during December, 8; total applications to date, 100; largest number of lights on at any one moment, 3,734, being 71 per cent. of the total connected.

Liverpool.—The electrical engineer has been empowered to proceed with a portion of the extension of the mains provided for by the estimates for the current year. The estimated cost of this work is £16,947.

London.—At last week's meeting of the Vestry of St. George, Hanover Square, a proposal was brought forward that an additional sum of £1,000 be granted on the lighting contracts in order that electric lighting might be introduced into the parish and the experiment made in Piccadilly. It was stated that the parish of St. George is behind all other metropolitan parishes in this matter. After discussion the motion was lost.

Loughborough. — A London company's proposal for obtaining a provisional order for electrically lighting the borough has been referred to the General Purposes Committee.

Merthyr.—Mr. Dan Thomas has given notice of motion to consider the expediency of including a sum in the next estimates, with a view to the engagement of an expert to report upon the electric lighting of the district, and probably on a scheme of electric tramways.

Newcastle.—A meeting of the Special Committee appointed over two years ago for the purpose of considering the provision of the electric light for the city was held last week. There was a discussion on the electric lighting of the city, and it was decided to ask the city engineer to report as to the number of arc lamps that would be required to illuminate the principal streets, and as to the power that would be required. It was felt, however, that it would be necessary to await the action of the new Tramways Committee before proceeding further, as should the committee decide in favour of electric trams, the same power might be used to supply the electric light. The city engineer is to furnish a report as to the amount of power to be produced from the waste energy of the Byker refuse destructor.

Newington.—Some members of the Vestry seem to fear that the London Electric Supply Corporation is cutting the ground from under its feet, by inducing the public to take current from it at 5d. per unit—a lower rate than the Vestry will itself be able to supply at when the municipal installation is put down.

Russia.—The annual report of the St. Petersburg and Moscow Electric Lighting Company for the year 1896-7 states, according to the *Shareholder*, that the total gross takings were £168,100, divided pretty equally between the two towns of St. Petersburg and Moscow, and the expenses were £101,000. The net receipts amounted to £59,160, and after deducting £5,060 for cost of administration for both towns there is a profit remaining of £54,100, of which £10,820 is written off for depreciation, £2,160 for Government taxes, and £4,640 for the reserve and insurance fund, leaving a net profit of £36,480, to which was added the sum of £11,300 carried over from the previous year, giving a total available for distribution of £47,780. A dividend at the rate of 6 per cent. was declared. The length of the streets in which cables have been laid is 33 miles, and next spring it is contemplated to put in 13 miles more, as the applications for connections are very numerous.

Salford.—At the last Council meeting, Councillor Wheatcroft asked how long it was intended to leave the electric lighting arrangements of the streets in their present condition with the wires exposed. He thought it was probable that there would be a serious leakage in consequence of this state of affairs. Councillor Hamblett, replying to the question, said that at the next meeting of the subcommittee, which had charge of the experiments, it would be suggested that the temporary arrangements referred to should be discontinued. It was a fact that there had been a considerable leakage and waste of electrical power.

Sheffield.—The City Council on Wednesday decided to purchase the Sheffield Electric Light and Power Company's undertaking. Pending the completion of the purchase shareholders are to receive 10 per cent. dividend.

Shoreditch.—In addition to the statement made by Mr. Kershaw at last week's Vestry meeting, we take from a local paper the following further remarks reported to have been made by him in answer to the objections raised by several members to too hasty a reduction in the charge per unit. Major Wenborn had stated that it would be very unwise of the Vestry to pass the report until they were placed in the possession of the information given in Committee. Mr. Kershaw said "this undertaking must be run in a commercial spirit. Their loss on the first quarter was £500, but in the second quarter they recouped that loss and got £300 to the good. One of the contractors had not yet fulfilled his guarantee, and if the figures given to the committee got into print it might be the worst day's work the Vestry ever did." This is a strong statement from the chairman of an electric lighting committee, and readers may be pardoned for wondering what figures it is so imperative to keep secret.

Shoreham.—The Southern Cross Shipyard and Engineering Company have offered to submit estimates and specifications to the District Council for electric lighting.

St. Marylebone.—For the electric lighting requirements at the new central administrative block at Marylebone Road Workhouse, 18 tenders were received, ranging from £870 to £1,765. It was proposed to accept the lowest (Messrs. H. F. Joel & Co.), but a member moved that the tender of the Marylebone firm be accepted at £927 odd. The matter was in the end referred to a Committee to make inquiries.

Stockton.—At last week's Town Council meeting the electric lighting question was under consideration. Mr. W. Ford, gas manager, had gone into the matter of site. He had selected three sites as being adapted for the purpose. So far, reasonable provision had been made, not only for covering the compulsory area, but for an area of something like five miles radius from the site selected. His design of the proposed buildings for engines, dynamos, and boilers had been approved by the expert. Mr. S. C. Vesey Brown reported that he had considered the three sites. He had estimated on a plant capable of supplying a total of 3,000 lamps alight, each lamp taking 30 watts. This meant that about 4,200 lamps of a similar size could be wired. The system was to be the continuous three-wire system with a pressure of 230 volts between either outer wires and the neutral wire. The cost of erecting and supplying an electricity works with boiler, economisers, engines, dynamos, pumps, pipes, crane, switchboard, storage battery, cables, meters, buildings, and chimney was:—Site No. 1, £15,145; No. 2, £15,652; No. 3, £14,297. It was resolved that a special meeting of the Gas Committee be held to consider the following resolutions:—"That the report be approved, the question of site being left for the consideration of the Council," and "That the Council be recommended to empower the committee to invite not exceeding six electric lighting engineering firms to submit sketch plans, specifications, and estimate of the cost of an installation to meet the suggestions contained in Mr. Ford's report."

Swansea.—It is probable we have heard the last of the triple scheme, which was the cause of so much local wrangling. The Lighting Committee has been going into the matter again, and as the Tramway Company seems determined to make their own arrangements for supplying the current for their system, the Committee has approved of a scheme for the electric lighting of the town independently. The provision of a day load for the plant was the chief matter of solicitude, but, from the promises received and the possibilities of certain works and industries taking power from the Corporation works, it is hoped by the committee that the scheme can be most profitably carried through.

Wallasey.—The chairman of the Gas Committee stated some days ago that their electrical installation, though only established about a year, had made a substantial surplus.

Winchester.—Mr. Murray, electrical engineer, Worcester, was to visit Winchester one day this week to inspect the plans and advise the committee.

York.—The question of dust destructors has been raised here in connection with electric lighting. A sub-committee is to report on the form of destructors.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

Airdrie and Coatbridge.—The directors of the British Electric Traction Company will probably concede certain points objected to by the Corporation Committee, so as to avoid opposition to the scheme when it comes before the Light Railways Commissioners in a few weeks.

Blackpool.—The electrical engineer, and such members of the Tramway Committee as please are to visit Hanover, Dresden, Berlin, and Paris, for the purpose of inspecting the electric tramway systems in those towns.

Bournemouth.—The promoters of the light electric railway schemes, which are opposed by some of the local authorities, are still pegging away, though, we are afraid, with little prospect of success.

Bristol.—The Sanitary Committee has reported to the Corporation at considerable length upon the Bristol Tramways (Extensions) Bill, and the Bristol Tramways (Electrical Power, &c.) Bill, being promoted by the Tramways Company. The Committee recommend the Council to resolve—(1) "That until the question as to the right of the Corporation to regulate the mode of traction to be used throughout the city on existing and future tramways, raised by the company by the promotion of the Electrical Power Bill, has been settled by Parliament, the consent of the Corporation be not given to the Extension Bill." (2) "That the Electrical Power Bill be opposed by the Corporation, and that the conduct of the opposition be entrusted to your Committee."

The Tramways Company met the sub-committee of the Sanitary Committee on 4th inst., for a conference on these matters, but nothing particular was done.

Clontarf.—A deputation has laid before the Corporation their views in favour of doubling the line of trams between Talbot Street and Nelson's Pillar. The Tramway Company considers the proposal tends to facilitate the traffic to Clontarf.

Dover.—For the week ended Saturday, 29th ult., the receipts were £103 odd, averaging £17 4s. per day, the number of passengers carried being 24,811 for the week. The total receipts since the opening have been £2,368 odd.

Dublin.—The directors of the Dublin and Lucan Steam Tramway Company report to the shareholders that they are still negotiating for the electrical equipment of the line.

Edinburgh.—A sub-committee has resolved that, as arrangements had already been made for the cabling of the line as far as Meadowbank, the Portobello section just acquired by the Corporation should be cabled likewise. At one time, it is said, there was some talk of the Portobello section of the system being worked by electrical traction.

Folkestone.—It is stated that though the Corporation have decided not to approve of either of the two schemes before them for the construction of electric tramways in the borough at the present stage, they do not intend to offer any active opposition.

Gateshead.—The Parliamentary Committee has had an interview with the Gateshead and District Tramways Company with reference to the suggested substitution of electric traction in place of steam on the tramways.

Great Orme.—There was a conference between the Council's representatives and the promoters of this tramway scheme at Llandudno last week, and it is understood that the promoters agreed to take the supply of electrical energy from the Council. The Council offered terms of purchase at the end of 28 years, on a basis of 4 per cent. dividend, but the promoters declined, and a 5 per cent. basis is probable.

Hastings.—Last week the Council had a lengthy discussion regarding the light railway and electric tramway schemes which had been proposed for the district by private companies. The Roads Committee submitted their report dealing with the proposals, stating the result of their negotiations with the promoters, and made the following recommendations:—1. That the scheme for a suggested system of tramways submitted by Mr. T. W. Barber, C.E., be not entertained. 2. That consent be not given to the Hastings and St. Leonards Tramways scheme. 3. That the Hastings and St. Leonards Light Railways scheme, of which the British Electric Traction Company, Limited, are the promoters—under which it is proposed to construct a line from a point near the west end of George Street *viâ* Castle Street and Robertson Street, to a point near the Bo-peep Hotel, and a line from the Albert Memorial *viâ* Bohemia Road to Hollington—be not assented to. 4. That consent be given to the carrying out of the Hastings, Bexhill, and District Light Railways (Electric) scheme, with certain stipulations; and that it be referred to the committee to negotiate with the promoters as to the terms and details, and report. These recommendations were not all approved by the Council. An amendment was carried receiving and adopting the report, excepting that part referring to the light railway scheme; no part of the front line is to be used for experiment with trams; all inland lines to be laid by the Corporation; the Town Clerk to oppose all schemes. The matter was referred to the Council in committee, the voting on the amendment being 26 in favour and five against.

Kirkcaldy.—The Provost and magistrates of Dysart have cordially taken up this electric lighting and tramway scheme, and appointed a committee to confer with the Kirkcaldy committee.

Leeds.—The Tramways Committee has decided to recommend the Council to extend the tramways from Wall End, Armley, to the city boundary at Stanningley. The Committee has also had under consideration the question of the equipment of the Headingley, Chapeltown, and Hunslet sections with electricity, on a similar principle to that employed on the Roundhay and Kirkstall sections, but the matter was postponed for a month.

Light Electric Railway.—The Earl of Jersey, Colonel Boughey, and Mr. Gerald Fitzgerald, Commissioners under the Light Railways Act, held an inquiry in the Middleton Town Hall on Saturday last to obtain information with regard to an application made by the British Electric Traction Company, Limited, for an order authorising the construction of a light railway in the district. Mr. S. Morse, of London, appeared for the company. The Lancashire County Council, the Middleton, Oldham, Rochdale, Heywood, Chadderton, and Castleton authorities, the Lancashire and Yorkshire Railway Company, and the Rochdale Canal Company were represented. They did not oppose the grant of the order, but sought to secure their interests under the order. From the statement of Mr. Morse it appeared that the Electric Traction Company propose to construct a tramway a little over 8 miles long, at an estimated cost of about £52,000, to run from Rhodes to Middleton, and to branch from thence in two directions, one running through Chadderton to Oldham, the other proceeding towards Rochdale by Castleton. The tramway is to be laid along the main road, on the electric overhead wire system. Evidence was given with regard to the great lack of means of communication by road between the places named, and it was stated that as the rails for the proposed system would be laid to the ordinary gauge of 4 feet 8½ inches, they could, as regarded the Oldham tramway system, be eventually coupled up or connected. The Oldham authority—the Town Council—opposed the grant to the company of power to construct a piece of the line, about 300 yards long, which would lie within the borough boundary. Oldham, it was said, might, when the present leases expire, decide to carry on its own tramway system. It was stated that there will be no engineering difficulties in laying the proposed line, and that no widenings of the road will be required. Asked as to the possibility of extending the line westwards from Rhodes to the Manchester tramway system at Cheetham Hill, Mr. S. Sellon, the engineer to the company, said that at the time the application was drawn it was understood that the Manchester Corporation were opposed to the overhead system. He understood it was now different, and if Manchester agreed there should be no difficulty in bringing the two systems together. The proposed tramway will run through a very populous district, which absolutely needed road connection. The Commissioners afterwards went through the clauses of the proposed order.

Liverpool.—The Tramways Committee are understood, says the *Liverpool Post*, to be working hard to have the experimental line of electric trams from St. George's Church to the Dingle ready and in working order by May 1st. The new machinery necessary to supply the motor power has already been laid down at the Paradise Street generating station, and the armatures rewound to give the more powerful 500-volt current necessary for the service. The wires have been manufactured and delivered, and the rails have already been shipped to Liverpool. Trolley poles have been specially designed for the Corporation, and one is now being cast from working drawings by Dr. Hopkinson. Several of the cars to be used on the line have already been delivered. Their design is novel. They are entered from the sides. The front part of the car is enclosed, and comfortably fitted up with seats divided one from another by arms as in first-class railway carriages. The ventilating arrangements are of the latest type, and the lighting throughout will be by electricity. The rear half of the car will be open, and will take the place of the present "outside." The seats are arranged cross-wise. Each car has been constructed to carry 36 passengers. As the speed will be too great to admit of passengers jumping on and off while the car is moving, it has been decided to have a stopping station at the corner of each important cross-street along the line of route. The rate of speed, with stoppages, will be eight miles an hour.

Madrid.—The directors of the Tramways Union Company, in their report for 1897, say that the formal sanction of the Madrid Municipality having been obtained for electrical traction, the work of transformation is now in active progress, and the directors hope the line will be in full working order early in the coming summer.

Manchester.—The Stretford District Council will oppose the Manchester Carriage and Tramways Bill, 1898, for using mechanical power on their lines, &c.

Norwich.—At the Norwich Police Court, on 3rd inst., an application was made on behalf of the Norwich Electrical Tramways Company, Limited, under the Land Clauses and Consolidation Act, for a certificate that the capital of the company had been subscribed, which was necessary before they could acquire any lands. Documentary evidence was handed in. It was shown that all the capital of the company (£240,000) had been subscribed, and 50 per cent. paid up. The magistrates, after consultation, said they had come to the conclusion that the evidence in its present state was insufficient to grant a certificate. The list of members produced was not verified in any way. The application was accordingly adjourned. The matter came before the Court again on 5th inst., and the necessary certificate was granted, an affidavit being produced from the secretary of the company stating that the book produced was the registered membership roll of the company.

Sheffield.—The construction of the track for the electric tramways is being pushed forward, according to the *Sheffield Independent*. Work was commenced on January 3rd. The road from Tinsley to the Wicker is practically level all the way. From Lady's Bridge, up Waingate, and then along the Fruit Market and up High Street, a heavy gradient is encountered, and the line runs through the busiest commercial part of the city, while, after leaving the Moor, the efficiency of the traction will be tried in Cemetery Road, by one of the steepest gradients to be found in Sheffield. If the electric overhead system proves equal to all the demands made upon it in the six miles from Tinsley to Nether Edge, it is likely to be successful in any other part of the city in which it is to be employed. The rails are supplied by the Barrow Steel Company; the steel points, crossings, &c., by Askham Bros. & Wilson, and Mr. R. W. Blackwell is supplying the well-known Chicago bond. The rails are laid on a solid bed of concrete. The city surveyor (Mr. C. F. Wike) is superintending the laying of the track. It is proposed to use 25 double-decked cars, each taking 51 passengers. The centre trolley poles, which will be fitted with lamp carriers, are being supplied by Messrs. Macfarlane & Co., of Glasgow, and a large number of the side standards will be made by Mr. J. Spencer, of Newbury. As already stated, the British Thomson-Houston Company will furnish the electrical equipment.

Electric Power Distribution.—At last week's meeting of the Dudley Town Council, a discussion took place with reference to the Electric Power Distribution Company and its proposals. The Mayor stated that he and Councillor Hooper attended the meeting at Birmingham in connection with the application of the Electric Power Distribution Company. That company was only in course of formation, and it was a mistake to say that they had offered power at 1d. per unit. It might be 1d. and it might be 3d. No offer had yet been made likely to induce that corporation to surrender their electrical powers. When they were ready with any such offer or guarantee that council would be ready to welcome them. He proposed the extension of the executive powers of the Electric Committee for two months, and this was carried.

Electric Power Distribution.—The representatives of the principal firms in the Mansfield district met at the Swan Hotel to discuss the proposed scheme of the General Power Distribution Company with the company's representatives. Mr. Devonshire (of the British Thomson-Houston Company) explained the proposals. Various questions were put as to the cost of the current to consumers, out and out cost, or hire cost of motors, &c. The Derby Town Council will oppose the company's Bill.

TELEGRAPH AND TELEPHONE NOTES.

Bolton Telephone Service.—In response to the complaints of the Bolton Chamber of Commerce as to the unsatisfactory condition of the telephone service, the Post Office authorities have replied stating that in so far as was practicable in the absence of details of specific cases, the matter has been carefully inquired into by the department's surveyor for the district. From a return which has been taken of the trunk traffic at Bolton, it appears that, of the trunk calls originated by subscribers at Bolton, 62·40 per cent. were put through, so far as the department is concerned, in less than five minutes, and 87·21 in less than ten minutes, and, on the whole, there does not seem to be any reason to suppose that a satisfactory service is not given.

Delays in Australian Telegrams.—The Postmaster-General of South Australia, Sir Charles Todd, must by this time have realised that the hopes which he expressed in a letter of reply to the protest made by the London Chamber of Commerce, complaining of the delays in the transmission of cable messages to Australia, were over sanguine. In this letter, dated Adelaide, August 31st, 1897, this gentleman, after suggesting that delays are due to various causes and that the lines in the Colony of South Australia were seldom at fault, says that "as a rule messages are transmitted very quickly over the line between Adelaide and Port Darwin, and our difficulties as regards the new code have been completely overcome; I do not, therefore, anticipate any further complaints." With the above opinion before us, it may not be out of place to detail the interruptions and delays which have occurred since the date of Sir Charles Todd's letter, viz.:—

September	6th, 1897.—	Port Darwin line unworkable.
"	17th, "	" " " interrupted.
November	19th, "	Both trunk lines cut off from Melbourne.
December	9th, "	Port Darwin line interrupted for about four days.
"	15th, "	Port Darwin line interrupted by floods.
"	18th, "	" " line working very badly north of Hergott Springs.
"	22nd, "	Both South Australian lines between Eucla and Adelaide unworkable for some hours.
January	4th, 1898.—	Considerable delay in press messages due to irregularity in the working of the landlines in Australia.
"	8th, "	Australian landlines working badly; no cables through from Adelaide.
"	19th, "	Cables from Adelaide delayed.
"	20th, "	Communication from Adelaide in many cases as much as 24 hours late.
"	31st, "	Delay in communication to London, unable to supply usual Adelaide prices.
February	1st, "	Government wires in Australia working very badly; telegraphic communication between Australia and England greatly delayed.

These interruptions, it will be seen, are by no means rare, occurring as they do on at least 13 occasions during the last five months. As he is a strenuous opponent to the Pacific cable scheme, a means by which the inconveniences referred to would have been avoided, it is interesting to gauge the value of the opinion so confidently expressed by the Postmaster-General of South Australia. It is widely suggested throughout the press, that a remedy for the above mentioned delays and interruptions will be found in a system of cables, which the Eastern Telegraph Company propose (for certain considerations) to lay to the Cape, and from thence on to Perth in Western Australia; but as this cable will land some 1,600 miles from Adelaide, 2,000 miles from Melbourne and 2,500 miles from Sydney, to say nothing of the 3,000 miles of landline intervening between Perth and Brisbane, it will be seen that the proposed remedy cannot be considered as in the least degree likely to supply the want which is so badly felt, not only in Australia, but in England.

The Deutsche See-Telegrafen-Gesellschaft.—We learn that the Emden-Vigo cable, which was laid about a year ago for the above-named company, has again broken down. If, as we have heard, this cable is intended to form the first link of a system which is to put Germany into communication with the United States without touching on English territory, it would seem prudent to duplicate the first section before going any further in the matter, as this is, we believe, the sixth occasion on which this cable has broken down in the space of a year. Such a record is not calculated to inspire much confidence in the minds of the Deutsche See-Telegrafen-Gesellschaft.

The London Authorities and the Telephone Service.—Both the Court of Common Council and the London County Council have been discussing in earnest the question of the telephone service. The L.C.C. is to obtain an inquiry into the service through an application for a licence to establish a municipal service for London. The Court of Common Council is applying for an inquiry and will hold a conference of local authorities at the Guildhall into the matter.

CONTRACTS OPEN AND CLOSED.

OPEN.

Bilbao.—February 28th. The Secretary of State for Foreign Affairs has received a despatch from Her Majesty's Consul at Bilbao, reporting that the provisional board appointed in connection with the electric tramway which it is proposed to lay from Zumarraga to Zumaya, in the province of Guipuscoa, invite plans and tenders, to be received by February 28th, for the construction and equipment of the line. Further particulars of the conditions of the tenders for the above-named tram line and branch, which together measure 30 miles, may be inspected at the Commercial Department of the Foreign Office any day between the hours of 11 and 6.

Belgium.—February 16th. Tenders are being invited by the Société Nationale des Chemins de Fer Vicinaux, of Brussels, for the supply of 38 electric tramcars. Tenders to be sent to, and particulars may be obtained from, the offices of the company, Rue de la Science, 26, Brussels.

Berlin.—March 15th. The Municipal Traffic Deputation of the Town Council have opened a competition for the construction of several new electric tramways in that city. Exhaustive details concerning this project are contained in the *Elektrotechnische Zeitschrift* of the 13th inst., which mentions that proposals will be received by the Stadtische Verkehrsdeputation Rathhaus III, Berlin, by March 15th.

Bristol.—February 21st. The Electrical Committee want tenders for 214 arc lamp posts. Electrical engineer, Mr. H. Faraday Proctor. See our "Official Notices."

Canterbury.—February 23rd. Tenders are invited for the electric wiring and fittings for the Beaney Institute for the Town Council. Specifications, &c., to be obtained at the office of the City Surveyor, 28, St. Margaret's Street.

Denmark.—The Formand for Byraadets Udvalg for Elecktricitetsvaertet (Sugförer Edv. Lau), of Kolding, are inviting tenders for the supply of (1) the engines and boilers; (2) the dynamos and other electrical plant and apparatus; and (3) the supply and laying of mains required in connection with the projected central electric lighting station in the town. Particulars may be had on applying as above for the sum of 50 krondos (returnable on receipt of *bonâ fide* tender). Tenders addressed as above.

Denmark.—March 12th. Tenders are being invited for the supply of the engines, dynamos, accumulators, &c., required in connection with the new central station at Frederiksberg, near Copenhagen. Tenders to be sent to the Frederiksberg Sporveis-og Electricitets Aktieselskab, Gammel Kongerie, 140, Copenhagen V., from whom particulars may be obtained.

France.—February 16th. Tenders are being invited by the French Naval Authorities at Toulon for the supply of circuit breakers, rheostats and dynamo wire. Particulars from, and tenders to, Le Bureau du Détail des Approvisionnements de la Marine Nationale, Toulon.

France.—March 31st. Tenders are being invited by the Municipal Authorities of Saint Chamond (Loire) for the concession for the lighting of the public streets of the town, either by gas or electricity. Particulars from, and tenders to be sent to, La Mairie de Saint Chamond (Loire).

Glasgow.—February 18th. Tenders are invited for the construction of several sections of tramways for the Corporation. Specification, &c., from Mr. John Young, general manager, 88, Renfield Street, Glasgow.

Hammersmith.—February 16th. The Vestry want tenders for general stores for the electricity works. See our "Official Notices."

Harrogate.—February 24th. The Corporation invite tenders for the supply and erection of vertical steam engine, dynamo, switchboard, motor, overhead conductors, &c., for sewage pumping plant. Mr. Geo. Wilkinson, borough electrical engineer. See our "Official Notices."

Italy.—February 16th. Tenders are being invited by the Italian Naval Authorities at Spezia for the supply of a large number of 12-C.P., 16-C.P., 25-C.P. and 100-C.P. incandescent lamps of different voltages. Tenders to be sent to La Dires Torpedine e Materials Elettrica, 1° dip. Marittimo, Spezia, Italy, from whence particulars may be obtained.

L.C.C.—February 16th. The London County Council Asylums Committee want tenders for a great variety of sundries. One of the items is for electric lighting sundries for Claybury. Particulars at the office of the Asylums Committee, 21, Whitehall Place, S.W.

Madrid.—February 22nd. The Secretary of State for Foreign Affairs has received a despatch from Her Majesty's Chargé d'Affaires at Madrid, enclosing copy of a Royal decree announcing that a public auction for the contract for repairing the national submarine telegraph cables during the next five years will be held at Madrid on February 22nd. Further particulars as to the cables in question may be inspected at the Commercial Department of the Foreign Office any time between the hours of 11 and 5.

Northwich.—March 5th. The Weaver Navigation Trustees are inviting tenders for the construction and erection of the necessary electric power plant for lighting and working the new swing bridges at Northwich. Current will be supplied by the Northwich Electric Supply Company. Engineer, Mr. J. A. Saner, M.I.E.E. See our "Official Notices" this week.

Pembroke (Ireland).—March 5th. The Lighting Committee want tenders for the supply and erection of various plant, machinery, &c., for electric lighting. See our "Official Notices" this week for full particulars. Consulting engineer, Mr. Robert Hammond.

Plymouth.—February 21st. The Council want tenders for the erection and completion of a refuse destructor with all necessary flues, fittings, boilers, &c. Borough engineer, Mr. James Paton, Municipal Offices.

Portsmouth.—February 22nd. The Corporation want tenders for the supply and erection of Lancashire boilers, feed pumps, mechanical stokers, &c. Consulting engineers, Messrs. Kincaid, Waller & Manville. See our "Official Notices" this week.

Redditch.—February 14th. The District Council want tenders for the supply of buildings, gas producing plant, gas engines, alternators, cables, transformers, &c., for the electric lighting of the district. Consulting electrical engineer, Mr. J. A. McMullen. See our "Official Notices" January 28th.

Rochdale.—February 19th. The Corporation want tenders for steam dynamos, balancer, and boosters, &c. Engineers, Messrs. Lacey, Clirehugh & Sillar. See our "Official Notices" January 14th.

Roumania.—March 15th. Tenders are being invited by the General Direction of the Roumanian Post and Telegraphs in Bucharest for the supply of 56,000 metres of galvanised iron and steel wire.

St. Helens.—February 21st. The Corporation want tenders for various plant and machinery, &c., in connection with the proposed electric tramways. See our "Official Notices" January 28th for particulars. Consulting engineer, Dr. J. Hopkinson.

St. Pancras.—February 22nd. The Vestry want tenders for dry back marine boilers with superheaters and brickwork seatings. See our "Official Notices" February 4th.

The War Office.—April 27th. The Secretary of State for War is prepared to receive offers, competitive designs and specifications for the supply of portable electric search light apparatus. Particulars from the Director of Army Contracts, War Office, Pall Mall, S.W. See our "Official Notices" February 4th.

Victoria.—March 21st. The Telegraph Department of the Victorian Government Railways is inviting tenders for the supply of alternating current transformers and one main switchboard. Tenders to the Telegraph Superintendent's Office, Spencer Street, Melbourne.

Wallasey.—March 17th. The District Council want tenders for the supply of engine, alternator, exciter, two Lancashire and one water-tube boilers, and condensing apparatus. Engineer, Mr. J. H. Crowther. See "Official Notices" this week.

Watford.—March 16th. The District Council want tenders for the supply and erection of various plant for the electric lighting of the district. For details of the seven sections see our "Official Notices" this week. Mr. W. C. C. Hawtayne, consulting engineer.

CLOSED.

Blackburn.—The contract for the 500-kilowatt C.C. steam dynamo for the Council has been placed with Messrs. Siemens-Belliss. The following are the tenders with Belliss' engines:—

	£	s.	d.
Electrical Company	6,500	0	0
Westinghouse	4,754	6	0
Crompton & Co.	4,666	0	0
J. A. Holmes	4,624	0	0
P. R. Jackson	4,492	0	0
Mather & Platt	4,405	0	0
Electric Construction Company	4,384	0	0
Siemens Bros.	4,340	0	0

The order for the steam alternator has not yet been definitely placed. Mr. Lacey is the consulting engineer.

Bradford.—We understand that the tender of the Westinghouse Electric Company, Limited, has been accepted for the electrical equipment of tramways in this city for the sum of £14,664.

Brighton.—The following is a list of the tenders submitted for the completion of the electric lighting, wiring, &c., of the Town Hall. Only those marked * were, says *Daily Tenders and Contracts*, entertained, they being the only tenders complying with the specification, which required samples of materials and fittings to be submitted:—

	£	s.	d.
Whipp & Co., Manchester	625	0	0
*A. H. Wood, Army and Navy Mansions, London, S.W. (accepted)	705	0	0
*H. V. James Mills & Co., Manchester	860	0	0
The Nelson Electrical Engineering Company, Nelson	874	0	0
Lawrence & Blaiberg, London, W.	875	12	0
*Page & Miles, Brighton	899	14	0
*C. G. Reed & Son, Brighton	965	10	0
*Laing, Wharton & Down, Ltd.	1,010	15	0
*W. J. Fryer & Co., Ltd., London, W.	1,288	5	0
M. Fileman, Brighton	1,500	0	0
E. A. Tasker, St. Paul's	1,865	0	0

London.—The following tenders were sent in for the electric light wiring of the Abbey Mansions, North Block, Victoria Street, S.W. Consulting engineer, Mr. Morgan Williams, C.E.:—

	£	s.		
Electrical and General Engineering Co.	1,656	0	0	
Hill, Gifkins & Co.	1,248	14	0	Estimated total, with branch wiring for 610 3/22 S.W.G. points.
H. M. Leaf	1,147	10	0	
Drake & Gorham	1,095	0	0	
Townsend, Tamplin & Makovski	1,046	2	6	
Laing, Wharton & Down	991	9	6	
Warburg, Dymond & Co.	968	0	0	
Belshaw & Co.	909	15	0	
C. A. Hemingway (accepted)	838	12	0	

London.—The following tenders were submitted for the electric light wiring of Messrs. Welch, Margetson & Co.'s new warehouse, Moor Lane, E.C. Consulting engineer, Mr. Morgan Williams, C.E.:—

Name of firm.	Tender No. 1 (Mains and Distribution Boards).			Tender No. 2 (Branch Wiring per point)				Estimated total for 721 points of 3/22 S.W.G.		
				7/21½ S.W.G. point.		3/22 S.W.G. point.				
	£	s.	d.	s.	d.	s.	d.	£	s.	d.
H. M. Leaf	390	0	0	28	0	22	0	1,188	2	0
Strode & Co.	247	0	0	30	0	21	0	1,004	1	0
Townsend, Tamplin and Makovski	278	18	9	21	6	17	6	904	16	3
Belshaw & Co.	230	0	0	27	0	15	0	770	15	0
Spagnoletti and Crookes (accepted)	270	0	0	18	0	12	0	702	12	0

Newport.—The contract for the supply of an electric lighting plant for 130 16-C.P. lamps and six 500-watt arc lamps for temporary lighting at Westwood waterworks for the Corporation has been given to Mr. C. D. Phillips, of Newport.

Stafford.—The County Lunacy Committee has reported that the Cheddleton Sub-Committee had invited tenders for the installation of the asylum with electricity, upon plans and specifications prepared by Mr. Henry Lea, C.E., of Birmingham, and of the four tenders received the following had been accepted:—Mavor and Coulson, £6,240 (generating and storage plant); Walsall Electrical Company, Limited, £3,195 16s. 6d. (wiring and fittings).

West Hartlepool.—It is stated that the following contracts have been given out by the Corporation for electric lighting plant:—Boilers, Anderton & Son; engines, dynamos, switchboard, motor-dynamos and arc lamps, Crompton & Co.; storage battery, Tudor Accumulator Company.

Dinner in Honour of Mr. James Dredge.—A dinner in honour of Mr. James Dredge, C.M.G., Executive Commissioner of the Brussels International Exhibition of 1897, took place on Wednesday night at the Grand Hotel, Trafalgar Square. Sir Albert K. Rollit, M.P., occupied the chair. On behalf of the exhibitors in the British section the chairman presented Mr. Dredge with a beautiful album containing a general view of the exhibition buildings and an illuminated address, to which were appended the signatures of the subscribers.

THE MAKING OF CHLORIDE ACCUMULATORS.

It is, perhaps, almost unnecessary to say that the company which make the chloride cell is the Chloride Electrical Storage Syndicate, Limited, and the syndicate practically controls the whole of the patents in the world, with the exception of the United States, Canada, and France, where chloride cells are made by allied companies. The original patents were held by the Electric Storage Battery Company, of Philadelphia, from whom the patents for this company and the rest of the world, with the above exceptions, were acquired by the Chloride Syndicate.

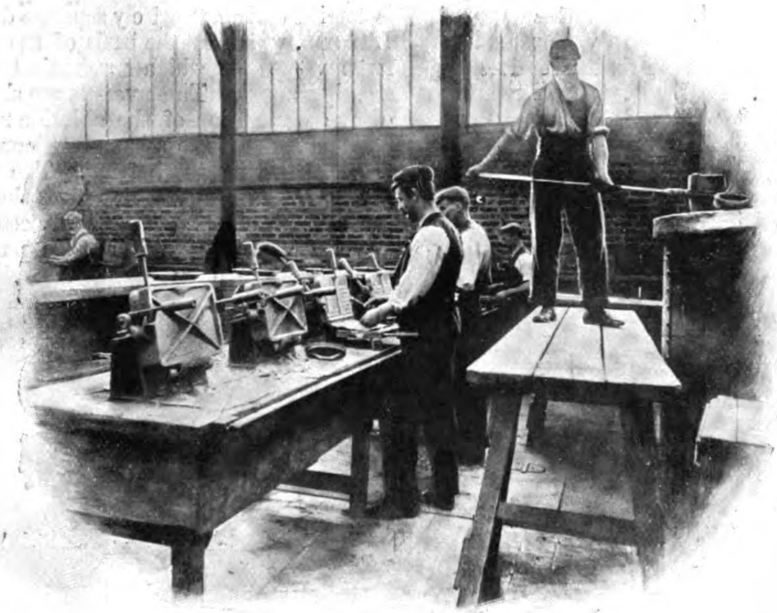

Fig. 2.—Casting Chloride Pastilles.

The home of the chloride accumulator is at Clifton Junction, some five miles from Manchester, and here an old chemical factory has been converted into up-to-date sanitary accumulator works. The conversion has been effected by pulling down old buildings, and erecting substantial, airy, and light ones in their place. The area of the works covers some three acres of ground, the greater portion of which is covered in. The site is most conveniently situated with regard to rail and water, the Bury and Bolton canal being contiguous to the works, and the railway within a stone's throw. There is more order, more cleanliness, and better surroundings than one usually associates with such works. The chairman of the company is Dr. Bowman, who is well known in electrical circles, and the general manager is Mr. G. A. Grindle, who, it is hardly necessary to say, is one of the best known engineers in the profession.

It is perhaps almost an act of supererogation to set forth the many directions in which the chloride accumulator has done distinguished service; but perhaps this account ought to include some reference to the growing use that is being made of the chloride cell. It is not only in electric lighting systems that this cell is performing good work, but in the perhaps more exacting services demanded in a tramway system. Some months ago we had occasion to describe the extensions that had been carried out on the Manchester Corporation electric lighting system, and we then took cognisance of the large battery that had been erected by the Chloride Company. When this battery was put

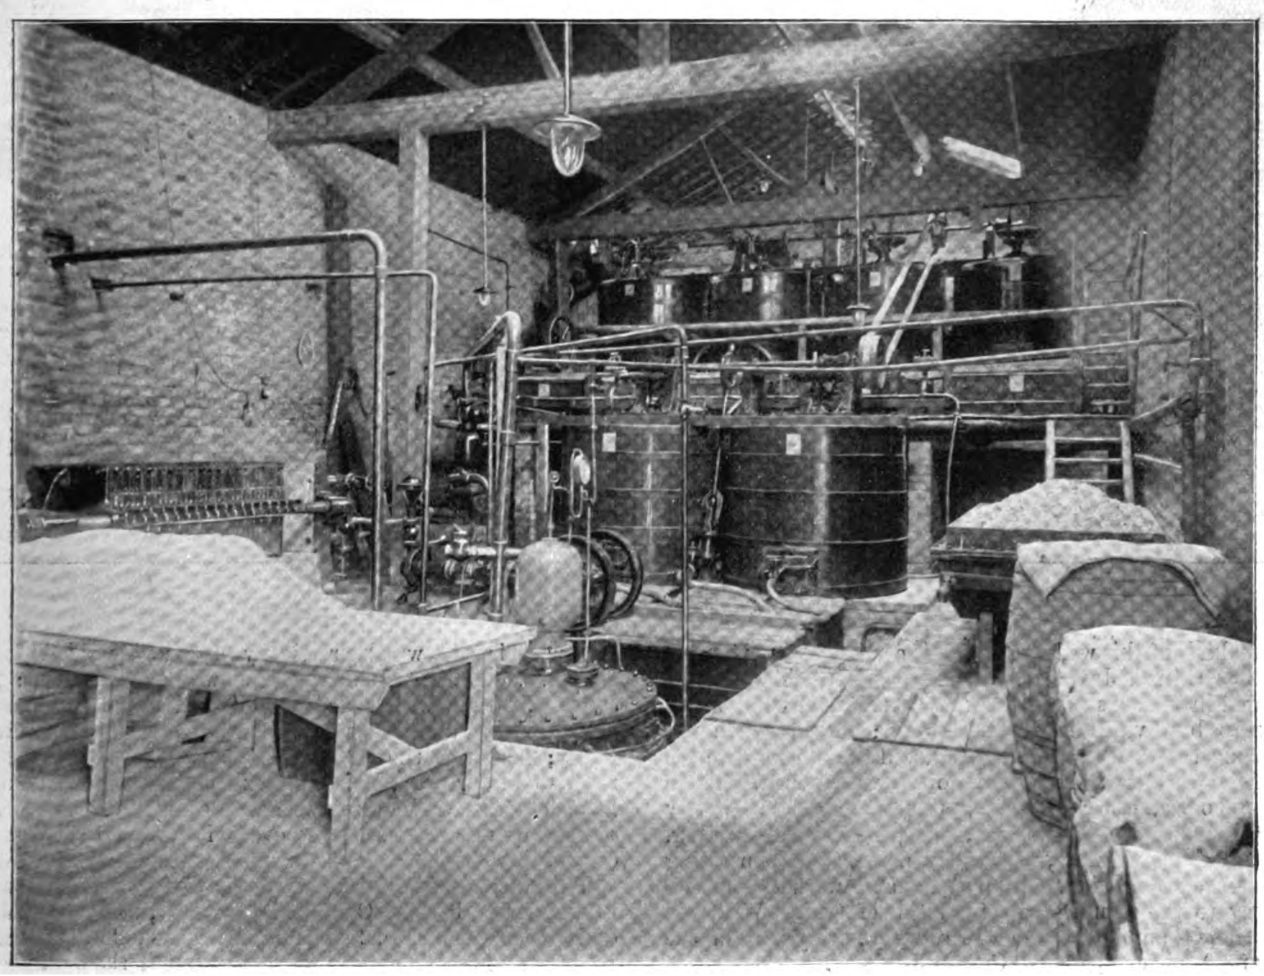

Fig. 1.—The Chloride of Lead Machinery.

down it was probably the largest in the country, and the objects that led to its introduction into the Manchester system were to save running a new feeder; to enable the station to be shut down at night, and to act as a balancing device. In every respect we believe this battery has been entirely successful. Although electric tramways are practically beginning in this country, the chloride accumulator has been intimately associated with some of the lines that have been completed. On the Douglas and Laxey line, this type of cell is used at a half-way house to assist the dynamos and to maintain the pressure; it is also serving similar services on the Snaefell Mountain Railway. At Leeds, the most recently completed tramway system, great reliance is being put upon chloride accumulators, where they are arranged in two substations.

The position attained by the chloride accumulator in the electrical industries is sufficient justification for giving some account of the various processes that attend its manufacture.

The name of the cell is obtained from the use that is made of chloride of lead which is employed in the negative plate, the positive plate being made up of ordinary metallic lead. It is, of course, the negative plate that constitutes the chief feature of this type of accumulator, and in accordance with the fitness of things we ought to describe the methods that are followed in the various stages of making the plate.

The first step is the manufacture of chloride of lead, which is carried on in an entirely separate department of the works. Litharge, which is the basis of the product, is dissolved in large vessels in which mechanical stirrers are being constantly rotated. These vessels are shown in the background of the illustration of the chloride room (fig. 1), and it will be observed that the stirrers are connected by suitable gearing and belting to shafting. The litharge is dissolved by means of acetic acid, which gives the resultant compound of acetate of lead. After the lead acetate has been drawn off and allowed to settle, it is then precipitated by means of

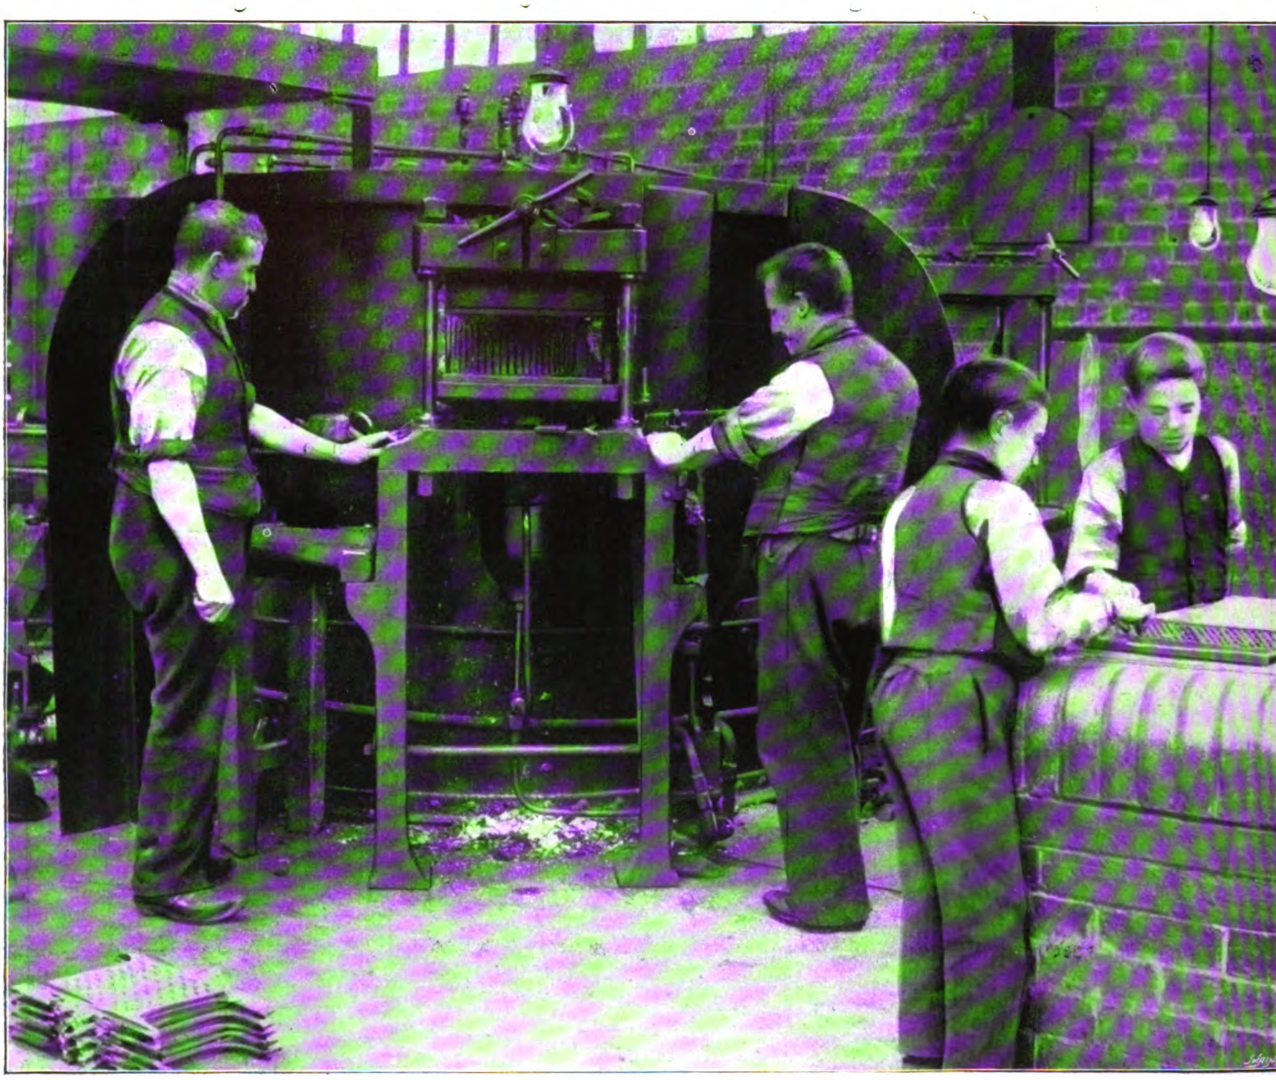

Fig. 3.—Framing the Pastilles.

The making of this well-known cell is carried on in extensive works at Clifton Junction, near Manchester. The process followed in the construction of this accumulator enables the works to be divided into two sections: one in which the mechanical work is done on the cell, and the other where the chemical and electrical manipulations are performed. There are, of course, other departments that are only indirectly associated with the cell making, such as the wood working, mechanics' departments, the boiler house, the generating station, the gas making, and a portion of the works is given up entirely to the manufacture of chloride of lead. With the exception of purchasing the raw material, every part of the accumulator is completed at Clifton Junction.

It is hardly necessary to say that both the manufacture of the positive and the negative plates call forth some very interesting and pretty operations, and by means of the illustrations we shall be able to demonstrate some of them.

hydrochloric acid, which practically gives us chloride of lead. The process is not quite so simple as we have described; for instance, when the compound has reached the acetate of lead stage it is carefully analysed, so that its nature is known to a nicety; moreover, the solution of chloride of lead is passed through a filter press, which squeezes out the acetic acid and leaves chloride of lead in the shape of whitish cakes. At one end of this room are large ovens in which the cakes of chloride are dried.

The chloride of lead next makes its appearance in what is known as the Pastille Casting Department, the name being derived from the special shape in which the chloride is used. In this room are large iron pans in which the chloride of lead is melted. The pans are protected by means of refractory linings, and a seal of lead, some inches in thickness, protects the bottom; they are capable of holding between two and three tons of molten chloride, and are heated by

Fig. 5.—Casting Negative Sections.

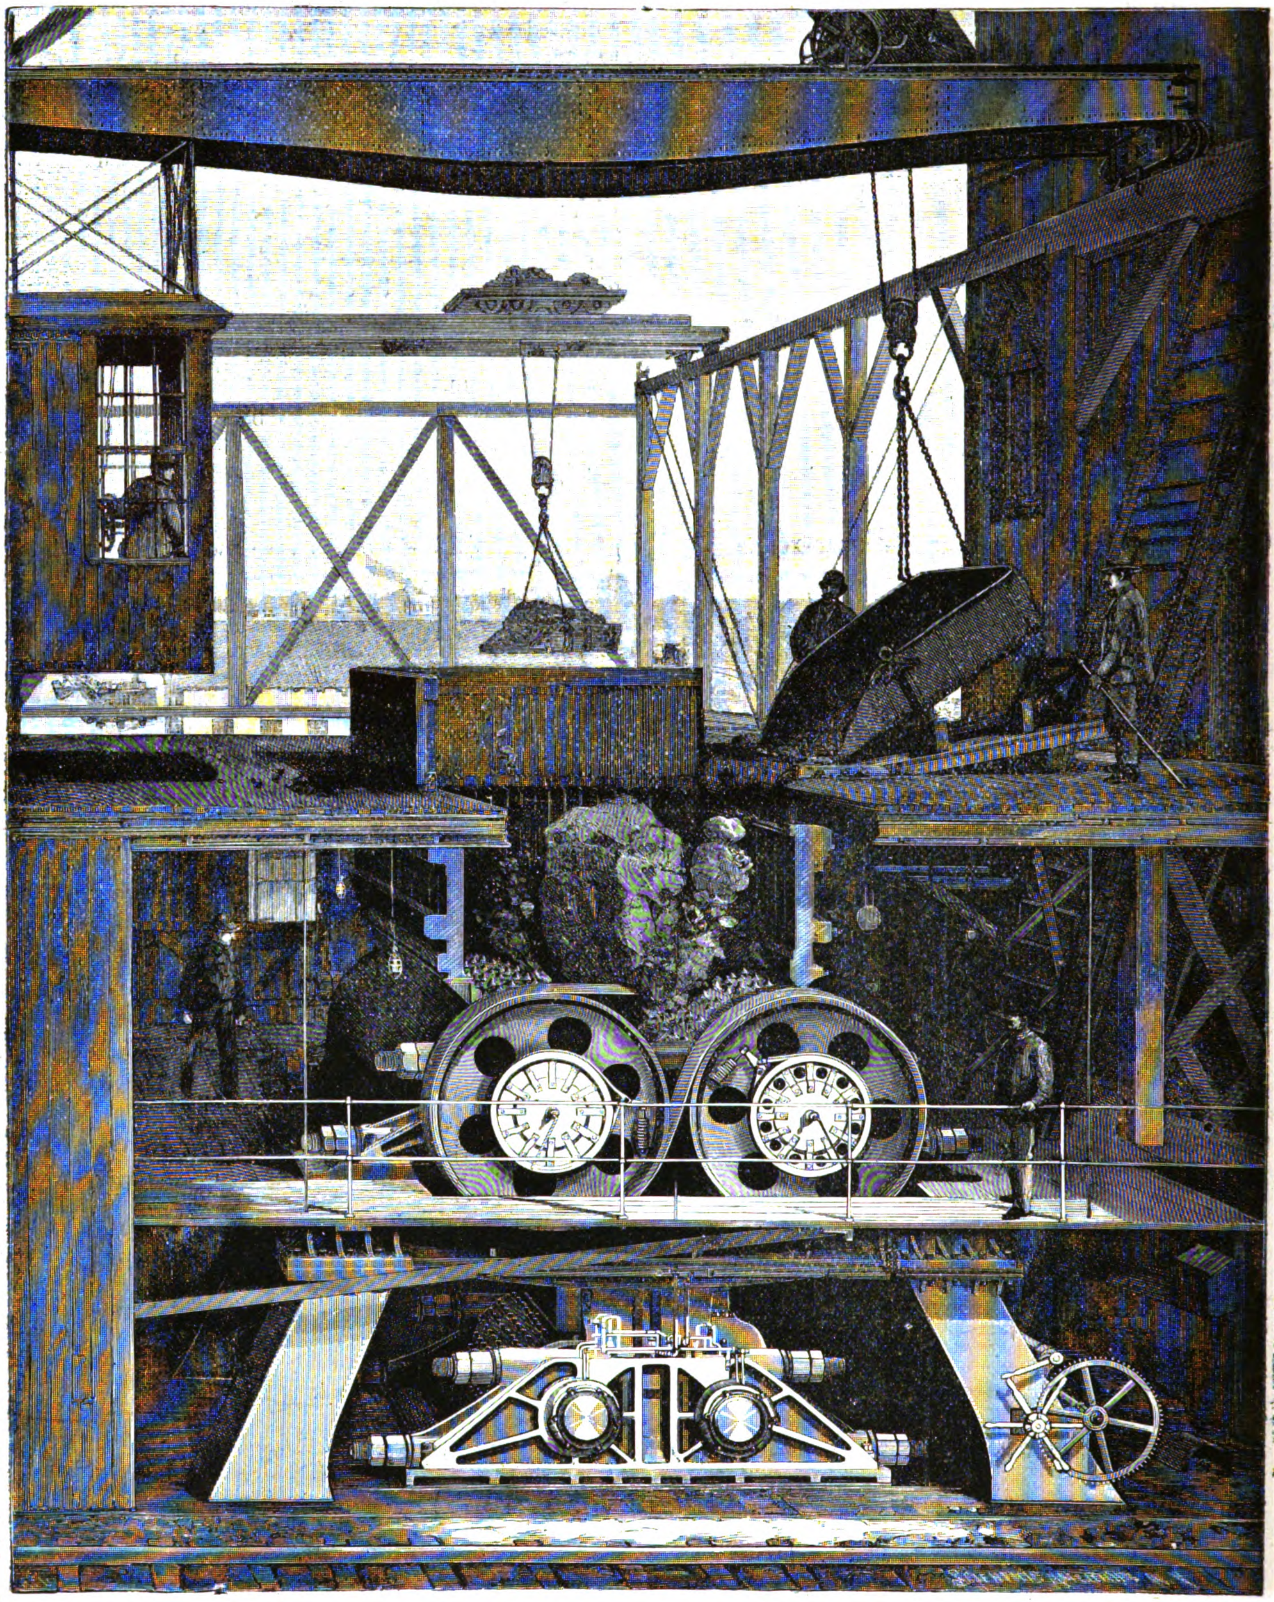
cast in moulds into small hexagon pastilles, suitable for framing. The operation of ladling the chloride and casting the pastilles is shown in fig. 2. The pastilles are then carried away to be framed, and this operation is distinctly interesting. The pastilles are arranged in the bottom half of a plate mould, the top half of the mould being permanently fixed to the top side of a hydraulic press. After the pastilles have been arranged on the mould, it is placed in position on the ram by means of stops, and water being admitted to the ram chamber, the press is closed, and the top half of the mould comes down on to the bottom half. The next operation is to inject molten lead under pressure to fill in the interstices left in the mould. This is done through a nozzle, which by means of a screw connects the molten lead chamber to the mouth of the mould. Compressed air is then admitted into the top of the lead chamber with the result that lead is forced into the mould, completely filling it and bedding in the pastilles. Fig. 3 shows one of the lead presses and boys placing pastilles in the lower half of the mould. The lead chambers are all submerged in a large pan of molten lead, four chambers and presses being arranged round each lead pan. The compressed air is delivered into the lead chambers at a pressure of 150 lbs. per square inch. The operation of the lead press is sufficiently safeguarded to prevent pressure being applied to the lead chamber until the press has been completely closed. Fig. 3 shows the operation of framing pastilles, the boys on the right of the illustration, whose expression has been lost in the complicated process of making the block, are fitting the pastilles into the lower half of the mould, and the men in the background are working the lead press. The next process is to trim the plates, and after this they are taken to the reduction tanks (shown in fig. 4) where they are set up alternately with rolled zinc plates, with the result that the chlorine in the chloride of lead pastilles leaves the pastille uniting with the zinc and forming chloride of zinc in the tank, the final state being that each pastille is converted into one of pure spongy lead. After a process of washing, the plates are then given

Fig. 4.—Reduction Sheds.

Dowson gas. The chloride is put into the pans with a small percentage of zinc, and becomes perfectly fluid at about 600° C. It is ladled out by means of plumbago ladles, and

a hydrogen bath to ensure absolute freedom from all trace of chlorine. That operation practically completes the making of the negative plate, they are not quite finished with, however, for they are then passed on to the plumbers, who cast them up into sections ready for sending out. Quite a simple operation is the casting up, and simply depends upon putting the plates in a specially shaped mould, in which molten metal is poured; the process of casting the negative sections is shown in fig. 5.

(*To be continued.*)



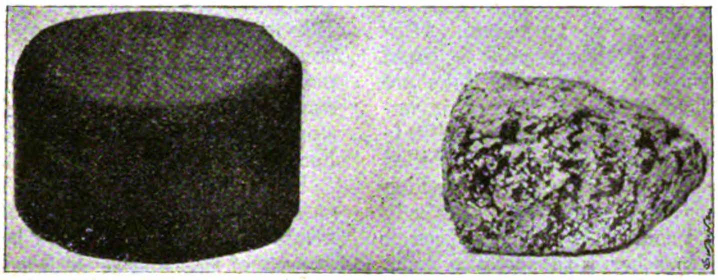
The Giant Rolls at the Edison Magnetic Concentrating Works.

THE EDISON MAGNETIC CONCENTRATING WORKS.*

Before describing the remarkable process of crushing and magnetic separation at Mr. Edison's concentrating works in the mountains of New Jersey, it will be well to speak of the elaborate system of prospecting which was carried out to determine the location of the various bodies of low grade iron ore which it is proposed to work by the new process. In iron mining, just as in gold mining, there is a limit to the grade or richness of ore which it is profitable to work in the existing state of the art. Hence the prospectors, who for many years have worked over the Eastern iron ore districts, have made no record of the existence of deposits which were not fairly rich in iron. As the Edison process was designed to render the hitherto neglected low grade ores commercially profitable, it was necessary to make a systematic prospect of the belt of magnetite deposits. The work was done by means of the dipping needle, and the survey was the most complete ever carried out. It embraced a strip of country 25 miles

* *Scientific American.*

wide, reaching from the Canadian border to the mountains of North Carolina. Several corps of surveyors ran lines across the magnetite belt at intervals of a mile, and wherever the dip of the needle showed indications of ore, a more thorough search of the locality was made. The results were plotted on a map, which is the most unique and thorough work of its kind in existence. When this was completed, the company proceeded to purchase or lease the most desirable properties, their holdings at present amounting to some 16,000 acres.



A Briquette, 68 per cent. of Iron. Fig. 2. A Lump of Iron Ore, 20 per cent. of Iron.

The New Jersey and Pennsylvania Concentrating Works are located on the site of the old Ogden mines, one of those many abandoned iron mines of New Jersey from which the veins of richer ore have been worked out during the century or more in which iron mining has been carried on in this district. The body of ore averages about 200 yards in width, and extends for a distance of over two miles. The average richness of the ore is about 20 per cent. of iron. It should be mentioned that although the works at Edison witnessed the first attempt to carry out magnetic concentration on a commercial scale, Mr. Edison had conducted a series of preliminary experiments at Llewellyn Park, N.J. The operations at Edison commenced about six years ago, and the characteristic energy and lavish expenditure with which they have been carried on have resulted in the present enormous and extremely interesting plant.

The visitor to Edison who is familiar with the scope of Mr. Edison's inventive genius — and who is not? — in the design and perfecting of such delicate or complicated devices as the incandescent lamp, the phonograph, or the vitascope, will find that in the totally different fields of mining and milling, with their massive machinery and vast operations, Mr. Edison has shown a characteristic originality and freedom from the trammels of tradition. This is evident, not merely in the application of an entirely new system of concentration, but in the preliminary work of mining and crushing, where, surely, most men would have been content to follow the beaten track.

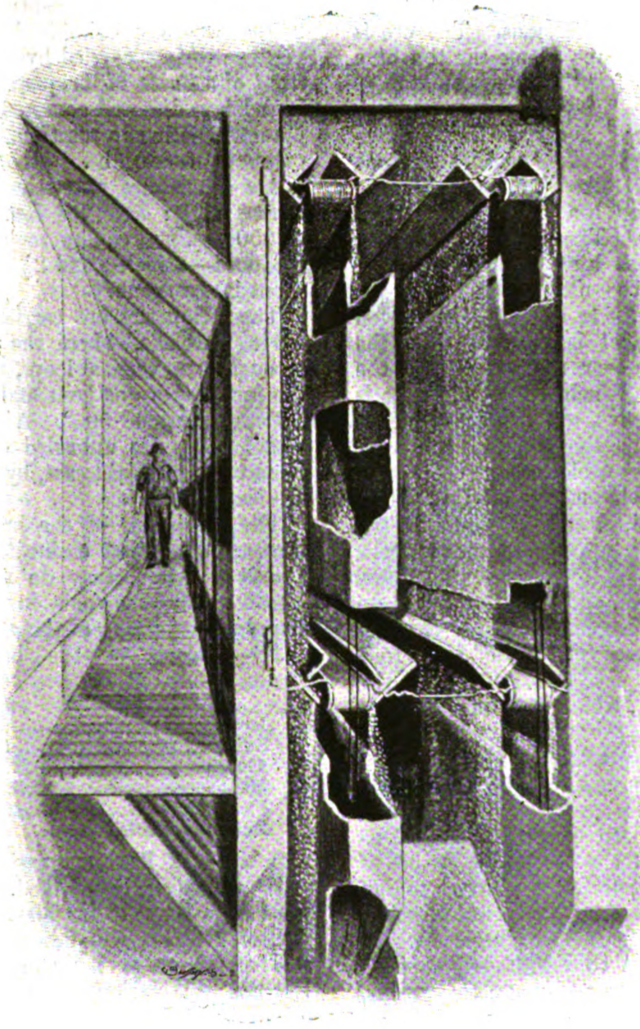


Fig. 1.

To carry out the process of magnetic separation called for the design of an entirely new plant in itself, and involved long years of patient and costly experiment; and, with a view of cheapening the work of getting out the rock and crushing it to the desired fineness for the magnets, an entirely new method of quarrying and crushing was devised and put into successful operation.

The works are situated approximately midway of the length of the deposit. A system of tracks runs from the crusher house to two powerful steam shovels which are working their way into the ore bed in two different directions. One of these weighs 60 tons and the other—a magnificent fellow weighing 93 tons—is the biggest of its kind ever built. In getting out the rock ready for the crushers, no attempt is made to shatter it to the usual size of, say, 100 lb. lumps by the free use of dynamite. The latter is used merely to loosen up the rock sufficiently for the great shovel to tear it loose and load it on the cars. Consequently it is frequently dug out of the cut in solid masses, weighing as much as five and even six tons apiece, and sent to the rolls in this shape. A double track, with a switch at the far end, runs through the cut on a slight up grade. The empties are pushed up and allowed to run back, by gravity, past the shovel, where the rock is deposited on 5-ton skips, of which there are two to each car. The tracks run on each side of the crusher house, and here the skips are picked up by a pair of 10-ton electric travelling cranes, and placed on an inclined table in front of the hopper above the "giant rolls." At the foot of this table is a revolving cylinder controlled by the operator, over which the material is fed to the rolls. This arrangement is clearly shown in the engraving on the previous page, where a load is shown falling from the skip into the rolls.

The giant rolls are what might be called the spectacular feature of the whole plant, and to see them seize a 5-ton rock, and crunch it with less show of effort than a dog in crunching a bone, gives one a vivid sense of the meaning of momentum—for it is momentum that does the work. The rolls are 6 feet in diameter, with a 6-foot face, and when they are running, the masses in motion weigh about 70 tons. They are spaced 7 feet 2 inches between centres, having a 14-inch space between their faces. The faces are covered with heavy cast-iron "slugger plates," which consist of a soft backing, with chilled 2-inch knobs. There are also two lines of massive knobs on opposite sides of one roll, which project 4 inches from the face. It is these which strike the smashing blows upon the large masses of rock, and break them up for the smaller knobs to act upon. The rolls are run at a normal circumferential speed of 3,500 feet a minute, and it is the energy stored up in the 70-ton mass at this speed which does the work. The rolls are driven by a belt, which serves to speed them up to the desired velocity, but is not depended upon to do the crushing. The pull of the belt is transmitted to the rolls by means of a strap brake acting on the neck of the rolls—as shown in the engraving—which is adjusted by means of a coil spring.

The 93-ton shovel and giant rolls combined do the work, which, in the ordinary methods of mining, is done by a freer use of dynamite, and it is just here that the first notable economy of this plant is realised.

The rock falls now upon the "intermediate rolls," shown immediately below the "giant rolls." They are 4 feet in diameter, have a 5-foot face, and are covered with knobbed plates. Their faces are $7\frac{1}{4}$ inches apart. The two sets can handle 3,000 tons of rock in a day of 10 hours. After passing through the intermediate rolls the rock is lifted by a wire rope elevator, in which the usual side links are replaced by side ropes in sets of four—an Edison invention, designed to reduce weight and lubrication and facilitate fast running—to a set of 36-inch rolls faced with chilled corrugated iron plates, the aperture between faces of which is about $2\frac{1}{2}$ inches. Unlike the giant rolls, these are positively driven; but to avoid breakage a connection is made through a split wobbler, which is held together with shearing bolts whose total cross section is such that they will shear off before any breaking strain can be transmitted to the rolls. From the first set of 36-inch rolls the rock passes down to a second set, which is similar to the first, but spaced with a $1\frac{1}{2}$-inch aperture. From these it falls into a third set, which are 24 inches in diameter, with a 20-inch face. These are not positively fixed, but are kept in place by coil springs.

By this time the rock has been crushed to a size of not over $\frac{1}{2}$ inch. It falls on to an elevator which carries it to the top of the "drier," a structure 9 feet square and 50 feet high, which is filled with a series of cast-iron plates 7 inches wide, which reach across the interior from wall to wall, and are arranged one above the other at an angle of 45°, the successive plates facing in opposite directions. The ore is then elevated to a conveyor which runs along the top of a stock house, 75 feet wide by 300 feet long, whose storage capacity is 16,000 tons.

From the stock house the material is carried to the three-high rolls in the concentrating mill. This consists of three rolls, the centre one of which turns in fixed bearings, while the upper and lower rolls are carried in bearings which are free to slide vertically in the housing. The lower roll is driven through a shearing wobbler, of the kind already described, and the bearings at each end of the upper and lower rolls consist of loose sleeves, on the outside of which are seven grooves. Around the grooves, that is to say, below the grooves of the lower sleeve and over the grooves of the upper sleeve, is wound an endless $\frac{1}{2}$-inch wire rope, which is finally carried up over a single sheave, which is acted on by a pneumatic piston. By this means the strain on the rope, and therefore the pressure of the movable rolls on the centre fixed roll, may be closely regulated, and an elastic adjustment is provided which removes all danger of breaking the rolls. The ore is fed between the upper and middle rolls and returned between the middle and lower rolls. The faces of the three-high rolls are smooth, and they are trued up in place when worn by means of a removable tool carriage mounted on the housing. There are four sets of these rolls in all.

The next step is the screening, which is carried on over 10 sets of 14-mesh screens. The rejections are sent back for recrushing in the three-high rolls, and the material which passes through the screens is now ready for the process of magnetic separation.

This process, which takes the place of what is known as the jig process of concentration, is the distinctive feature of the Edison plant. The crushed material is allowed to fall in a thin sheet in front of a series of magnets, which deflect the magnetic particles, but allow the non-magnetic rock to fall in a practically vertical line. A thin knife-edged partition board separates the magnetic and non-magnetic streams, technically known as, respectively, the concentrates and tailings, the concentrates being taken to the drier and subjected to further screening and magnetic separation, and the tailings, in the shape of sand, being sold as building sand in the open market. The latter, on account of its sharpness, is in great demand, and the company readily disposes of all that the works produce.

There are three sizes of magnets: The 12-inch, the 8-inch and the 4-inch. The crushed ore is first allowed to fall in front of a series of three 12-inch magnets (Fig. 1). The tailings, or the crushed particles of rock which are not drawn over by the magnets, are allowed to go to the sand heaps, while the concentrates, which have been drawn out of the falling stream by the magnets, are carried to a drier or sent back to the three-high rolls for recrushing. The dried concentrates are then passed through 50-mesh screens and allowed to fall in front of a series of three 8-inch magnets. The tailings again go to the sand heap and the concentrates are taken to what is known as the dephosphorising room, where they are treated by a special process, invented by Mr. Edison, for reducing the phosphorus. From this room the concentrates are allowed to fall in front of a series of 4-inch magnets, the tailings being sent to the sand-heap and the concentrates being taken back for recrushing or being stored in concentrate stock houses. The stock in these houses carries a percentage of 68 per cent. of iron.

It was at this point in the process that a difficulty was encountered which called for an extended series of experiments and much costly work before it was overcome. The process of smelting in the blast furnaces demanded that, for the best results, the ore should not be delivered in the finely divided state which characterised the concentrates from the Edison plant. It was necessary to furnish the material to the furnaces in a condition which would allow the furnace gases to act upon it to the best effect. The Edison concentrates, on account of their fine subdivision, would be apt to choke the furnaces and prevent the rapid reduction of the ore.

In order to meet this requirement, it was decided to compress the concentrates into briquettes (fig. 2) and deliver them in this form to the blast furnaces. A complete briquetting plant was therefore designed, which has fulfilled all requirements. The concentrates are carried to a mixing house, where a suitable binding material is added, the mixture being carried by means of a trough conveyor in front of a series of briquetting machines. The mixture is forced into dies and compressed in them by means of three plungers, acting in rotation. The first fills the die under a pressure of 800 lbs. to the square inch; the next plunger exerts a pressure upon the briquette of 14,000 lbs. to the square inch; and the last plunger exerts a pressure of 60,000 lbs. per square inch. Two sizes of briquettes are produced—3 inches and $2\frac{1}{2}$ inches; the larger sizes weighing about 20 ozs. each.

The briquettes are carried by a bucket conveyor to the baking furnaces, where the conveyor passes up and down through five vertical loops, the briquettes being retained in the furnace for one hour and nine minutes, and exposed to a temperature of 500°. After they have been thoroughly baked, they are unloaded on to a conveyor, which carries them to the railroad cars, by which they are taken direct to the blast furnaces.

The behaviour of the briquettes in transit and at the furnaces has been eminently satisfactory. They do not absorb moisture, they do not break in handling and they present sufficient voids in the blast furnaces to insure a complete circulation of the gases around them for smelting.

An analysis of the briquettes shows the following results:—

	Per cent.		Per cent.
Iron	67	to	68
Silica	2	to	3
Alumina	0·4	to	0·8
Manganese	0·05	to	0·10
Phosphorus	0·028	to	0·033
Binding material	...	to	0·075

with traces of lime, magnesia and sulphur.

It will naturally be asked, What results have the Edison briquettes shown at the blast furnaces when tested in actual practice? This was determined in 1897, by a trial which was carried out at the Crane Iron Works, Catasauqua, Pa. In these tests various percentages of briquettes were tried in a furnace, which produces an average of 105 tons of pig per day, when using the ordinary burden. The test was started with 25 per cent. of briquettes, and extended over five days, 100 per cent. of briquettes being used on the last day. With 25 per cent. of briquettes, the output was 104 tons of pig, and with 100 per cent. of briquettes the output rose to $138\frac{1}{2}$ tons per day.

From a study of these figures the reader will see that the yield of pig is largely increased by the use of the briquettes over that secured by the use of the usual ores. Moreover, the trial proved that the consumption of limestone is reduced from 30 per cent. to 12 per cent. of the charge of ore, with a corresponding reduction in the quantity of fuel used.

The question has frequently been asked: How can this system of concentration be made commercially profitable with its elaborate plant and its frequent rehandling of the material? The answer is, that the principle of labour saving, by the adoption of automatic appliances, which has enabled American industries to compete successfully against the world, is here carried out to its fullest development in every part of the works. In the mining, with its giant 83-ton shovel; in the "giant rolls" crushing; in the elevators running at a speed of 250 feet per minute; and in the system of magnetic separation, there is a minimum of manual and a maximum of mechanical labour.

Costly and elaborate as the plant may be, it is noteworthy that about 5,000 tons of ore per 20 hours can be mined, crushed and concentrated with a working force of only 125 men per shift. From the time the deposit of ore is loosened by blasting ready for the steam shovel to the time when the concentrated result is shipped on the cars in the shape of briquettes ready for the blast furnaces, the material never once calls for manipulation by hand.

Herein lies the promise and potentiality of this latest and most radical development in the mining and metallurgy of iron.

NOTES.

The General Electric Company.—On Saturday evening last the staff of the General Electric Company, Limited, held its eighth annual dinner and smoking concert in the Empire Room of the Trocadero Restaurant. Some 160 ladies and gentlemen were present, the guests being numerous, and more or less well known in electrical circles. In proposing respectively the toasts of the "Guests" and the "Staff," Mr. Gustave Byng and his brother Max developed a talent for witticisms which would have done credit to Scotchmen; and Mr. Bevis, in reply to the second toast, gave an impromptu address on three-phase working which took all the scientists present by surprise at the very simplicity of the system. The banquet was followed by a well-arranged smoking concert, and the humorous ditties, especially those of a cerulean hue, had an immediate effect upon a certain transient luminous body, which, uneasy during the early hours of the evening, speedily found peace and happiness in Paradise regained. At the time we made the acquaintance of Mr. Gustave Byng, some 16 years since, he had been guilty of reading a paper before a society which shall be nameless, and in a place where he would scarcely venture now, and his staff consisted of his brother and an office boy. To-day the General Electric Company's employés number some 1,600 all told, and it is not a little curious to observe how the figures 1 and 6 enter into this brief notice of a successful firm. Employers (and here we take the opportunity of including Mr. Hirst, who has just returned to convalescence after a serious illness) and employed, are alike to be congratulated on the gigantic undertaking which has been evolved from such a small beginning.

The Glasgow Technical College Electrical Engineering Laboratory.—Owing to the liberality of Mr. George Weir, late of the Holm Foundry, Cathcart, who resigned his directorship of the Technical College when he went to Australia, the above laboratory has recently been presented with a delicate Sullivan's universal galvanometer for the measurement of voltages, currents, and resistances. This galvanometer, as we have already pointed out, possesses several novel qualities, and is equally well suited for use on board a telegraph ship and a laboratory on shore.

Smoking Concert.—A staff smoking concert of the City of London, Metropolitan, and London Electric Lighting Companies will be held at the Freemason's Tavern, Great Queen Street, Holborn, W.C., on Friday, February 18th, at 7.30 p.m. Hon. secretary, Mr. A. W. Whieldon, 64, Bankside.

Electric Power from the Shannon.—It is stated that a company has been formed to utilise the water power of the Shannon for the development of electricity. The directors of the company, which is called the Shannon Electric Power Syndicate, Limited, are Lord Lurgan (chairman), Colonel Sir Gerald Dease, J. F. Bannatyne, D.L., Vere Ward Brown, and Richard W. Booth. It is proposed to construct a canal from a point above Castleconnell to the outlet below Doonass, to provide for storage of a certain volume of water in Lough Derg during the summer, and the company are in communication with the Limerick Fishery Board, so that fishery rights on the river may not be interfered with by the intended scheme.

Royal Institution.—At Tuesday's meeting the special thanks of the members were returned to Mrs. Tyndall for her liberal donation of £1,000, presented in the name of the late Dr. John Tyndall, D.C.L., F.R.S., for the promotion of science. Thanks were also returned to Sir Frederick Abel, Sir Andrew Noble and Prof. Dewar for donations to the fund for the Promotion of Experimental Research at Low Temperatures. It was announced that the centenary of the Royal Institution would be celebrated next year.

Municipal Electrical Association.—Mr. A. B. Mountain, the secretary of this association, informs us that at a meeting of the Council of the Municipal Electrical Association, held at the Westminster Palace Hotel on Friday, the 28th ult., Mr. A. H. Gibbings was (as stated in the Electrical Review last week) elected president for the year 1898. It was decided to hold the Convention in London on June 8th, 9th, and 10th, papers having been arranged upon the following subjects: Management of Electrical Undertakings; Repayment of Loans and Appropriation of Profits; Uniformity of Plant and Apparatus; Electric Traction; The Use of Accumulators in Connection with Lighting and Traction Systems; Switchboard Apparatus; Auxiliary Apparatus; Stand-by Supply. Mr. J. E. Stewart, of Derby, was elected a member of the council, and the following applications were considered and approved. Elected as members: T. A. Chamen, Glasgow; J. E. B. Thornhill, Taunton; H. W. Clayden, Morley; T. H. Minshall, Croydon; A. L. C. Fell, Sheffield; Electric Lighting Committee, Stockport; Electric Lighting Committee, Morley. Elected as associates: D. McFarlane McLeod, Aberdeen; P. S. Thompson, Huddersfield; W. N. Legge, Halifax; A. Sugden, Halifax.

City and Guilds of London Institute.—The students of Finsbury Technical College will hold their annual conversazione at the above College on the 18th inst. Dr. Thompson has promised to lecture on "Wireless Telegraphy." Mr. Ives will give an exhibition of colour photography, and glow-lamp making will be demonstrated by Mr. Robertson.

The Royal Society.—The following was among the papers to be read before this society yesterday afternoon: W. G. Rhodes.—"Contributions to the Theory of Alternating Currents."

Appointment Vacant.—The Crown Agents for the Colonies want an electrical engineer in connection with the working of an electric light plant at Lagos, West Coast of Africa, for six months at £25 per month. See our "Official Notices."

Coventry Technical Institute.—Prof. Ayrton gave the address at the annual meeting and prize distribution in connection with the Coventry Technical Institute, on Friday. He urged that British manufacturers should be more enterprising in inducing wants in the people. He referred to the progress of electrical traction in America, and remarked that while the steam locomotive had given way to the electric motor on American modern overhead railways, the use of electric traction on the underground railway in London, where it was of more pressing necessity, was only under consideration. The substitution of electric traction for horse traction in the streets might interfere at first with the employment of some people, like stablemen, harness makers or corn dealers, but ultimately the number of people employed by the practical application of scientific principles in the development of electric traction, would certainly be enormously increased.

Webb Testimonial.—The executive committee are now issuing to contributors resident in the United Kingdom and Ireland invitations to the Presentation Reception which will be held at 9.30 on Monday, the 21st, at the Whitehall Rooms of the Hotel Metropole, immediately after the dinner already announced.

Northern Society of Electrical Engineers.—The annual dinner of this society is to take place at the Grand Hotel, Manchester, on Thursday, 17th inst., Mr. Raworth presiding.

Lectures.—A lecture on "Earthquakes and Other Movements of the Earth's Crust" was delivered by Prof. John Milne, F.R.S., on 3rd inst., before the Wolverhampton Literary and Scientific Society.

At the Wakefield Mechanics Institution, on Monday last week, Mr. H. Scholey delivered a lecture on "Some Modern Applications of Electricity." The lecturer showed numerous experiments in electric lighting, transmission of electrical power, electric welding and smelting, and electrodeposition of metals, and interest was added to his remarks by several lantern slides, showing the progress which had been made in electric lighting and traction within the last seven years. Mr. Scholey had the loan of apparatus from the General Electric Company, the Lithanode Company, Mr. F. J. Borland, Messrs. Cuttriss Wallis & Co., and the Electric Metal Working Syndicate.

Before the Glasgow Architectural Association on 25th ult., Mr. W. B. Sayers delivered a lecture on "Electric Light, Heat and Power: their Efficient Installation and Cost."

At a meeting of the Aberdeen Mechanical Society in Robert Gordon's College, on 1st inst., Mr. Alfred Blackman, city electrical engineer, read a paper on "Public Electricity Supply."

Obituary.—We hear with deep regret of the death of Mr. G. K. Winter, F.R.A.S., which occurred at Madras on January 17th. Mr. Winter joined the Madras Railway Company in the year 1864, and had, therefore, completed a long period of service in India. He was telegraph superintendent of the Madras Railway Company from its very commencement. To him that company was indebted for its "block" system. He had several patents for block signalling instruments, and his system was employed not only on the Madras, but other railways in India, New Zealand, and South America. His latest invention was the improvement of the electrical block ticket service apparatus which is now being taken up. We learn that experiments with his inter-communication system are now being conducted in England, several carriages being now in progress of fitting up for the purpose of a Board of Trade inquiry. Previous to going out to India, he was assistant to Mr. W. T. Ansell, in Ireland, for the Electric and International Telegraph Company. The deceased gentleman was a member of several electrical and other scientific institutions, and 25 years ago he contributed a paper to the British Association on "The Use of Electromagnetic instead of Electrostatic Induction in Cable Signalling." He was a valued contributor to the ELECTRICAL REVIEW as long ago as 1872. Mr. Winter was in failing health last year, and came home for a few months' leave. He returned to India feeling better, but he had only been back on Indian soil a couple of months when the end came.

FORTHCOMING EVENTS.

1898.

Friday, February 11th.—Second day of the annual general meeting of the Institution of Mechanical Engineers, at 25, Great George Street. Discussion on Mr. Philip Dawson's paper on "Mechanical Features of Electric Traction." A paper and discussion on "First Report to the Gas Engine Research Committee; Description of Apparatus and Methods, and Preliminary Results," by Prof. Frederic W. Burstall.

Physical Society (rooms of the Chemical Society, Burlington House). Annual General Meeting at 5 p.m.—Address by the President. After which at an Ordinary meeting: "On Electro-magnetic Induction in Plane, Cylindrical and Spherical Current Sheets, and its Representation by Moving Trails of Images," by G. H. Bryan, M.A., F.R.S.

At 9 o'clock. Royal Institution, Albemarle Street, W.C. "The Metals used by the Great Nations of Antiquity," by J. H. Gladstone, Ph.D., D.Sc., F.R.S., &c.

At 8 o'clock. Institution of Civil Engineers (Students). "Protection of Power Transmissions from Lightning," by J. T. Morris.

Monday, February 14th, at 8 o'clock. Northern Society of Electrical Engineers, at Palatine Hotel, Victoria Street, Manchester. Paper by Mr. J. G. Statter, on "Electric Cranes."

Yorkshire College Engineering Society. "The Steam Turbine Engine, and its Applications," by J. D. Baillie (C. A. Parsons & Co.).

Latest date for Redditch Corporation electric lighting plant tenders.

Wednesday, February 16th.—Liverpool Engineering Society, Royal Institution, Colquitt Street. Paper by Dr. J. H. T. Tudsbery, M.I.C.E., on "Engineering Survey Work."

At 8 o'clock.—Society of Arts, "The Protection of Industrial Property," by J. F. Iselin, M.A., LL.M.

At 7 o'clock.—Third of Prof. Thompson's course on "Electro-deposition," at the City and Guilds Technical College, Finsbury, E.C.

At 12 o'clock.—The last of Mr. Mervyn O'Gorman's three lectures on "The Design and Testing of Power Cables for Specific Purposes," at the Central Technical College.

At 7.30 p.m.—Institution of Electrical Engineers. Students' meeting, Mr. F. K. Jewson will read a paper on "Telephones and Telephonic Apparatus."

Thursday, February 17th, at 8 o'clock. Chemical Society, Burlington House. Papers to be read:—"Some Lecture Experiments," J. Tudor Cundall, B.Sc. "Observations on the Influence of the Silent Discharge of Electricity on Atmospheric Air." W. A. Shenstone and W. T. Evans.

At 7 o'clock. Annual dinner of the Northern Society of Electrical Engineers at the Grand Hotel, Manchester. Mr. J. S. Raworth will preside.

Friday, February 18th, at 6.30 p.m.—Institution of Electrical Engineers. Students' visit to the generating stations of the St. Pancras Vestry. Applications to join this party should be made at once to the Students' Hon. Sec. (Mr. S. Grant, 28, St. Mary Abbot's Terrace, W.)

Finsbury Technical College Conversazione. Lecture on "Wireless Telegraphy," by Dr. S. Thompson, &c.

At 7.30 p.m. Staff smoking concert of the City of London, the Metropolitan, and the London Electric Lighting Companies, at the Crown Room, Freemason's Tavern, Great Queen Street, Holborn, W.C. Chairman, Mr. P. W. D'Alton.

Tuesday, February 22nd.—The Federated Institution of Mining Engineers, 26th general meeting at Newcastle-upon-Tyne. Various papers on mining matters are to be read, and among those to be open for discussion are the following: "Light Railways," by Mr. Leslie S. Robinson. "A One-rail or Trestle System of Light Railway," by Mr. Fred. J. Rowan. "On Some Dangers attending the Use of Steam Pipes," by Mr. A. L. Steavenson. "Machine Coal-mining in Iowa, U.S.A.," by Mr. H. Foster Cain. "Latest Developments and the Practical Application of Alternating Multiphase Machinery for Power Transmission," by Mr. Walter Dixon. Visits will be paid to the Telegraph and Telephone Departments at the General Post Office, Mr. A. W. Heaviside, Superintending Engineer.

Wednesday, February 23rd.—Second day of the Federated Institution of Mining Engineers. Various excursions, including visit to the works of Ernest Scott & Mountain, Limited, Newcastle-on-Tyne.

CITY NOTES.

Cambridge Electric Supply Company, Limited.

THIS company continues to show most striking progress, and it has now reached the prosperous state indicated by a 6 per cent. dividend. We have more than once pointed out the difficulties that this company has to contend with in the shape of a curious load, and the success achieved under the peculiar conditions prevailing in Cambridge amply demonstrates the soundness of electricity supply business generally. The increase in the year's output has not been especially marked, it being only 12 per cent. upon that of the previous 12 months.

The following are the chief points in the directors' report:—

During the year 1897 there has been added to the company's mains, the equivalent of 2,562 8-candle-power lamps, making the total 21,195. The number of units supplied has been 221,507, an increase of 23,992 or 12 per cent. The total cost of coal has been diminished by 5½ per cent. 42 new consumers have been added, making the total 329.

The capital expenditure for the past year has been £5,872 11s. 4d.; 2,027 yards of main conduit pipe and cable have been laid down, making the total at present 15,298 yards. To insure the continuity of supply in the event of an accident to any one line a duplicate system of distribution has been nearly completed, a large amount of the cable laid has been for this purpose.

During the year the mains have been extended from the end of Regent Street as far as Norwich Street and Harvey Road, a sub-station having been built to supply this district. Preparations have been made to convey the mains to Madingley Road in order to supply the new Presbyterian College, now building, and the district.

The company after paying all charges, placing £400 to the reduction of preliminary expenses, and £300 to depreciation account, has a balance of £2,460 19s. 10d., which, added to £278 19s. 7d. brought forward from last year, makes £2,739 19s. 5d. An interim dividend of £953 9s. 10d. and interest on debenture and temporary overdraft £48 1s. 8d., have already been paid, leaving a net balance of £1,738 7s. 11d., out of which the directors recommend the payment of a dividend of 3½ per cent., making, with 2½ per cent. already paid, 6 per cent. for the year. This will absorb £1,445 11s. 1d., leaving a balance to carry forward of £292 16s. 10d.

The following table gives the cost per unit:—

	1897.	1896.
Total capital expended...	£48,922	—
Number of units sold	221,507	—
Number of lamps connected	21,195	—
Revenue from sale of current	£5,856	—
Net revenue	£2,461	—
Average price obtained per unit ...	6·3d.	

Cost of Production.	£	s.	d.		Per unit.
Coal	1,099	0	0		1·19d.
Oil, waste, water, and engine room stores	134	0	0		·14d.
Salaries and wages at generating station	803	0	0		·87d.
Repairs and maintenance of buildings, engines, boilers, dynamos, &c.	417	0	0	Works' cost 2·65d.	·45d.
Rent, rates and taxes	339	0	0		·36d.
Management expenses, directors' remuneration, salaries of managing engineer, secretary, clerks, &c., stationery and printing, general establishment charges, auditors, law charges and insurance	669	0	0		·72d.
Depreciation of buildings and plant account	—				—
Renewal fund account	—				—
Total	£3,461	0	0		3·73d.

Revenue.	£	s.	d.	Average price obtained per unit.
By sale of current	5,858	0	0	—
Meter rents, &c.	293	0	0	—
Other items	473	0	0	—
Total	£6,624	0	0	—

Total cost per unit (exclusive of depreciation and renewal accounts), 3·73d.; works' cost, 2·65d.

The Electric Lighting Companies' Dividends.

The following are the complete dividends of electric lighting companies up to the moment of going to press:—

London.	1897.	1896.	1895.	1894.
	%	%	%	%
Charing Cross and Strand Electricity Supply	7	6	5	—
St. James' and Pall Mall	14½	10½	7½	6¼
Westminster	12	9	7	5
Provincial.				
Cambridge Electric Supply Company	6	5	3½	—
Newcastle-upon-Tyne Electric Supply Company	7	5	—	—
Scarborough Electricity Supply Company...	5	—	—	—
Yorkshire House-to-House Company	6	6	5	4

The St. James' and Pall Mall Electric Light Company, Limited.

The ordinary general meeting of the shareholders of this company was held on Tuesday last at the offices, Carnaby Street Central Station, Golden Square, W., Mr. Eustace J. A. Balfour in the chair.

The Chairman, in proposing the adoption of the report and accounts, said: "Gentlemen, before I ask you to pass the resolution, I will just briefly go through a few points, and I will ask any gentleman afterwards who may have any questions to ask to put them to me, and I will endeavour to answer them satisfactorily. The working of the past year, as you will have seen by the accounts, has been, on the whole, very satisfactory. At the end of the year we have 126,000 8-candle-power lamps connected, being an increase of about 18,000 for the year, and there is reason to believe that with the growing increase in popularity of electricity, both for lighting and power purposes, this rate of increase will not only be fully maintained, but largely exceeded. Recognising that such an increase will be best obtained by reducing from time to time the price to consumers, the directors have had put into force, from January 1st, a new rate, by which 6d. per unit is charged for the first £100 of the annual bill, and 4d. per unit for the rest, while all electricity for motive purposes is charged 3d. per unit. The St. James' Company now stands ahead of all other companies as regards its works' cost and total cost per unit sold, and we think this is a very creditable position for a company like this, which is by no means the biggest in the metropolis. Out of the profits of the year the directors propose to pay a dividend of 14½ per cent. We see at once that this dividend will excite a certain amount of criticism from local authorities and other consumers, and, perhaps, others interested; but, in reply to this, I want to point out that the average price of 5d. per unit, which the board will receive for the current year, is a fair and reasonable one, and considerably below the statutory price, and below the charges made by most other Metropolitan electric light companies. The ordinary, and, in fact, the total capital of the company is exceedingly small for its output, as compared with other companies, and the directors hold that the shareholders are entitled to a fair return as the result of careful expenditure and good management. Moreover, this dividend of 14½ per cent. is fictitious, for under the articles of association the founders' rights compel a division of the whole of the surplus without allowing for any reserve—a very necessary item in a business of this description. Happily for all parties an agreement with the founders—subject to your approval to-day—is practically settled, and the company will then be at liberty to provide a proper reserve fund, which will render the credit and dividends of the company more stable. I think it should be clearly understood that we have a lease of life of only 35 years from this year. The investment, therefore, is rather like a leasehold investment, in which you would not only expect a fair return for your money, but would also expect to be able to put by such a sum as at the end of those 35 years would leave you where you stood before you made the investment. It should also be borne in mind that, although we have very little in the way of precedent to go upon as to the price at which a concern of this kind would be purchased, yet what little precedent we have in the case of the County Council and the tramways is absolutely against the probability of our receiving anything at all for the goodwill of the concern; it would simply be a valuation of the buildings, plant, and machinery and property. Therefore it should be recollected that a 14½ per cent. dividend does not, and should not, represent the true earnings of the company. It appears on the face of it to be a very large figure; but if we were able, as we shall be able I hope in the future to deduct from that money to form a redemption fund, then I hope no local authority, or any of our customers will have any just grounds for complaint, and at the same time, of course, the shareholders will be benefitted to exactly the same extent as they are at present. The extension of the Carnaby Street station will shortly be completed, and the company will then have a total horse-power of over 6,000, with mains of sufficient capacity to carry the full output, and it is anticipated that with this provision, the company's works can be carried on with the existing stations for two further winter seasons. The directors attribute a large portion of the success of the company to the fact that it has been their policy to keep their resources, in the way of plant, &c., well ahead of their requirements, so that they have been able to deal with their customers promptly, and to carry out alterations in their system without interfering with the supply. Following out this policy, it has become necessary to provide at once for further extensions of the company's work, so that it may be ready before their present resources are outrun. The directors have therefore secured a valuable freehold site in every way most suitable for the most economical generation of electricity, and they are now carefully considering the best methods of dealing with this extension in the best interests of the shareholders. As the negotiations are necessarily very delicate, the directors trust that the shareholders will be satisfied with this statement, that in all future issues the policy of the directors of giving a preferential allotment to their own shareholders will be continued, and before raising any large amount of capital they will take an opportunity of putting the scheme very fully before the shareholders. I have nothing more to add, but, as I said, I shall be very happy to answer any questions that may be put to me."

Mr. Latimer Clark seconded the resolution.

Mr. Foster said he noticed that £12,000 of the proposed new shares of £5 each were to be issued to the holders of the founders' shares, but he should like to know to whom the balance of 8,000 would be allotted, and at what price? According to the articles of association, the directors were entitled to 10 per cent. on the interest paid, which, for the past year, amounted to £3,000. They had, however, only credited themselves in the accounts with £2,500. Was that to be taken as a precedent?

The Chairman replied that apart from the proposed issue to the founders in exchange for founders' shares, all issues of capital were governed by the articles of association, which provided that "subject to any direction to the contrary that might be given by the meeting that sanctions an issue of capital, all new shares shall be offered to the members in proportion (as nearly as conveniently can be), to the existing shares held by them."

Mr. Foster enquired if the privilege would be extended to new shareholders.

The Chairman said it would apply to all on the register at the time of the issue. As to the directors' fees, he said that the action of the board this year in taking less than the sum to which they were entitled, was not to be considered as a precedent.

Mr. Bowin thought the shareholders would like to know the intentions of the directors with reference to the proposal made some time ago for reducing the interest on the debenture stock of 3½ per cent.

Mr. Leaf, one of the directors, said the reason the board made the proposal referred to by Mr. Bowin, was that they thought they were paying too much. So soon, however, as they had settled matters with regard to the founders' shares and the new extension site, they hoped to be able to deal with the interest on the debenture stock.

The resolution was carried unanimously.

The retiring directors were then re-elected, as were also the auditors.

An extraordinary general meeting followed, at which, on the motion of the Chairman, seconded by Mr. Latimer Clark, the resolutions passed at a recent extraordinary general meeting, approving of an agreement with the founders' shareholders, and an increase of the capital to £300,000, were unanimously confirmed.

Anglo-American Telegraph Company.

The ordinary general meeting of the proprietors of the above company was held on Friday last at Winchester House, Old Broad Street under the presidency of Mr. F. A. Bevan, the chairman.

Mr. P. H. Wells (the secretary) having read the advertisement convening the meeting, the report was taken as read.

The Chairman, in proposing the adoption of the report, said he had very few observations to make. As they had probably observed, the report itself contained very little, and happy was the country that had no history. However, he was glad to say that what he had to tell them was of a cheerful nature. For the first time since 1884 they were able to declare a dividend of 3 per cent. upon the ordinary stock, which meant the maximum dividend of 6 per cent. on the preferred stock. He thought that was matter of congratulation, especially when they took into account that it did not arise from any spasmodic increase of traffic, but that it was the result of a steadily-growing traffic, which had been increasing during the last four or five years. He would give them the figures as to the share that came to the Anglo-American Company out of the pooled traffic during the last four years. Four years ago the figure stood at £284,000; the next year it was £307,000; the next £326,000, while in the year they were now reviewing, it was £354,000, which gave an increase of £70,000 in four years, while during the same period the expenses had remained practically at the same figure, viz., £111,000, so that the shareholders had reaped the full benefit of the increase of traffic. But notwithstanding that large increase of traffic, the directors would not have been able to pay a 3 per cent. dividend, unless they had been helped by what he might call a considerable amount, from the work of their repairing ship, *Minia*. In the first half of the year, the *Minia* earned for them £8,455, and in the last half, £2,820, making altogether £11,275, and he would like to impress upon the shareholders that but for that windfall, as he might call it —for they could not calculate that they would always make that amount out of their repairing ship—they would not have been able to pay the dividend of 3 per cent. The shareholders would be glad to know that the current year had opened very well, and that the receipts for January were a record over every other January that they had ever had, and therefore they began this year with things looking very well. One, of course, could not predict that that increase would continue, but they might fairly hope that this current half-year would be a good one. He would now compare the figures of the last half-year with those of the corresponding six months in 1896. For the half-year under review, their total net increase of receipts was £9,258 7s. 10d., and the increase of expenses was only £371 16s. 8d.; but he might add that the increase in the expense of repairs of cables amounted to £469 9s. 3d., and therefore, but for that increase, there would have been an actual decrease in the expenses. They brought forward to the current half-year £6,704 0s. 8d. more than in the corresponding half of 1896, so that they had available for dividend £15,590 more than at that period. The dividend in February, 1896, was at the rate of 29s. per cent.; what they now proposed was at the rate of 33s. 6d. per cent. That meant an increase of £15,750, rather more than the figure he had given above, so that they carried over £159 8s. 2d. less than they did in the corresponding period of last year. He thought the shareholders would consider those statements very satisfactory. Coming to the renewal fund, he would remind them that the directors attached very great importance to that fund, which, in their opinion, was not as yet at all equal to what it should be, taking into consideration the fact that their cables were getting older each year, and that the two oldest cables were 24 and 23 years old, so that if they had to replace one of those cables they would have at once to spend a very large portion of the renewal fund. During the past year they had only added £33,000 to the fund, for though, according to their usual practice, they had taken £24,000 from the revenue, and the interest amounted to another £20,000, they had had to spend £11,000 in repairing their 1880 cable, so that the net result was that they had only added some £33,000 to the fund. It now amounted nominally to £760,000 odd, which was only about 10 per cent. of the capital, and he ventured to express the hope that no shareholder would suggest to the directors that they should in any way cease from maintaining that reserve fund, but that the shareholders would back the directors in continuing to add to it. Regarding the investment of the fund, a portion of it constituted their working capital, and some was invested in their leasehold premises at the end of Throgmorton Street. They had over £600,000 invested, but the market value would be considerably in excess of that sum. But looking at all the circumstances; to the age of their cables, and that they had no other fund to apply to, he trusted they would agree that the fund was by no means too large, and his (the chairman's) own opinion was that it was not nearly large enough. He was glad to be able to say that their cables were all in good working order, except a short cable on the other side, which broke down since the report was printed. But that was really a matter of no moment, and when the proper time came it could be mended without difficulty. He was also able to say that their traffic had never been carried better than it was now, and that the staff had never been more efficient. Since he last addressed them, he had had an opportunity of visiting the station at Valencia, and was very much pleased with all he saw there. One of the oldest men in their employ—Mr. Graves, was superintendent there, and a most valuable man he was. He had got together a staff of very efficient workers, and all that he saw there of the work gave him great satisfaction. It was in great part owing to the efficiency of their staff that they were able to maintain the traffic, and therefore increase the dividend.

Sir Gerald Fitzgerald, K.C.M.G., seconded the motion.

Replying to a short discussion, the Chairman said the policy of the board was to carry on the company, and do what was best for the good of the shareholders generally, irrespective of what were called the rights of preferred or deferred shareholders. He had all along been of opinion that it was a mistake to have split up the stock, but at the time it was forced upon the directors by the shareholders, so that the board were not responsible for it.

The report was then adopted.

Sir Gerald Fitzgerald and Mr. C. Burt, the retiring directors, were re-elected, and the auditors were also re-elected for the current year.

Newcastle-upon-Tyne Electric Supply Company, Limited.

The directors' report to the tenth general meeting of the shareholders states that the demand for electricity continues to improve satisfactorily, the units sold having been 660,906, against 535,953 last year. The total profit for the year, including the balance brought forward from last year, represents a sum of £5,059 10s. 3d. Out of this the directors recommend a dividend at the rate of 7 per cent. per annum for the year, on account of which an interim dividend at the rate of 5 per cent. per annum was paid on July 15th last. The total dividend will absorb £3,144 15s. 6d., leaving a balance of £1,914 14s. 9d., which the directors have dealt with as follows:—

	£	s.	d.
(a) In writing off the preliminary expenses in connection with the recent increase of capital sanctioned last year	62	15	0
(b) In increasing the reserve and depreciation account to £2,200 by a further sum of	1,200	0	0
(c) In carrying forward to next year the balance of ...	651	19	9
	£1,914	14	9

In order to meet the developments rendered necessary by the constantly increasing demand for electrical energy, it is intended to issue, at once, part of the new capital sanctioned at the last general meeting. The directors recommend that the shares be offered to existing shareholders *pro rata* at a premium of £1 10s. per share: the amount of this premium to be added to the fund for depreciation and reserve. The directors feel themselves greatly indebted to the Durham College of Science for assistance in scientific questions on various occasions in their past history, and they desire to receive authority from the shareholders to make an annual subscription of not exceeding £50 to that institution.

The Cuba Submarine Telegraph Company, Limited.

The report of the directors for the half-year ending December 31st, 1897, to be presented at the fifty-third ordinary general meeting of shareholders, to be held on February 16th, 1898, states that the gross receipts amount to £19,167 7s. 9d., and the gross expenditure to £6,602 10s. 9d., leaving a sum of £12,564 17s., which, added to the balance of £3,317 9s. brought from the last account, leaves £15,882 6s. at the credit of revenue account. The sum of £4,827 17s. 1d. has been added to the reserve fund, together with £1,274 7s. profit on investments realised, while £17,830 4s. 10d. part cost of the new Manzanillo-Santiago cable, and £271 19s. 3d. for repairs have been charged to this account, leaving a balance of £106,000 to its credit. The dividend on the preference shares will absorb £3,000 and leave £8,054 8s. 11d., out of which the directors recommend the payment of a dividend on the ordinary shares at the rate of 6 per cent. per annum, free of income-tax, the balance, £3,254 8s. 11d., being carried forward to the current half-year. The traffic receipts show a decrease of £9,662 17s. 9d. as compared with the corresponding period of last year, due principally to the loss of the French company's traffic, which is now conveyed by that company's new line between Hayti and New York, as explained in the report of December 31st, 1896. The directors much regret that, owing to the falling off in the receipts, a reduction in the rate of dividend on the ordinary shares has become necessary. In consequence of the establishment of the new line between Bermuda and Jamaica—subsidised by the British Government on the basis of a charge of 3s. per word between the United Kingdom and Jamaica—the Cuba Company have been compelled to accept reduced rates which will result in a considerable loss of income. The new cable between Manzanillo and Santiago, referred to in last report, is now being laid, and on the completion of this work the vessel will proceed to the repair of the Cienfuegos-Santiago 1881 cable. The other sections of the company's cables have continued in good working order throughout the half-year, with the exception of some slight repairs to the harbour lengths at Santiago.

United Ordnance and Engineering Company, Limited.

The prospectus of the above company (with which is incorporated the business of Easton, Anderson & Goolden, Limited), has been before the public this week. The authorised capital is as follows: £275,000 in £1 5½ per cent. cumulative preference shares; £275,000 in £1 ordinary shares; £250,000 4½ per cent. first mortgage debenture stock. The whole of this £800,000 has been offered for subscription. The company is formed:—

1. To manufacture and sell guns, gun carriages, ammunition, and war material, and to carry on business as electrical, hydraulic, mining, and general engineers.

2. To acquire a licence dated November 19th, 1897, granted by Messrs. Schneider & Co., of Creusot and Havre, the celebrated manufacturers of guns and war material, to manufacture and sell the Schneider-Canet artillery.

3. To acquire and take over as a going concern the undertaking of Easton, Anderson & Goolden, Limited, the well-known engineers, of Erith and London.

The last item (3) is arranged in order to lessen the delay inseparable from the establishment of new works. Messrs. Easton, Anderson and Goolden's premises and plant are valued by Messrs. Fuller, Horsey, Sons & Cassell in a report dated April, last year, as follows:—

Freehold engineering works, with fixed and loose plant (exclusive of goodwill), £202,257.

Messrs. W. P. Peat & Co., value the stocks, stores, and assets of the undertaking in hand on June 30th, 1897 (exclusive of goodwill), £154,955, making the total £357,212, which sum is subject to liabilities at June, 1897, amounting to £35,956.

The business has been carried on from June 30th, 1897, down to December 31st, 1897, from which date it is to be taken over by the company, on the account and at the risk of Mr. Ernest Terah Hooley, who will indemnify the company against any risk of loss arising from the recent engineers' strike and lock-out, or otherwise during that period. The agreement for the purchase of this business provides that Messrs. Wilson & Baynes, directors of Easton, Anderson and Goolden, Limited, shall be appointed managing directors of the company for a period of five years. In addition to the manufacture of ordnance and war material, the company will continue, develop and extend the general engineering business of Easton, Anderson and Goolden, Limited, and in connection therewith special attention will be devoted to electrical traction and electrical transmission of power, in both of which branches there will undoubtedly be great developments, both at home and abroad, in the immediate future. Several important schemes have been submitted to Easton, Anderson and Goolden, Limited, and will be carefully examined by the directors of this company.

The directors of the company are Admiral Sir H. F. Nicholson, K.C.B., H. McCalmont, M.P., F. Elgar, LL.D., F.R.S., Charles Cammell, Colonel Paget Mosley, T. Perceval Wilson (chairman of Easton, Anderson & Goolden, Limited), a managing director: H. K. Baynes (director of Easton, Anderson & Goolden), a managing director. The secretary is Mr. W. E. Davies, and the registered office is at Broad Sanctuary Chambers, Westminster, S.W. The list closed on Wednesday, 9th inst.

Liverpool Overhead Railway Company.

The ordinary half-yearly general meeting of the Liverpool Overhead Railway Company was held on Tuesday, 8th inst., at the Law Association Rooms, Cook Street, Liverpool. Sir Wm. Forwood, chairman of the company, presided.

The report showed that the gross revenue receipts for the half-year amounted to £37,583, and the working expenses to £24,240, after deducting the interest on mortgage debentures; and adding the balance of £3,810 brought forward from the previous half-year, there was £13,753 available for dividend. Out of this it was proposed to pay dividends of 5 per cent. on the preference shares, and 3½ per cent. on the ordinary shares, leaving £2,878 to be carried forward to next half-year.

The Chairman, in moving the adoption of the report and accounts, said he had pleasure in being able to congratulate the shareholders upon the progress and position of the company. In the corresponding half of last year they paid a dividend of 3 per cent. per annum, and last half-year 3 per cent., making 3¼ for the year with the dividend recommended that day. During the year they had paid to the Liverpool Tramway Company £2,000, in conformity with the terms of their agreement with them. That agreement had now come to an end, having terminated on the 10th of last month. There had been an increase in the traffic during the past six months of 545,000 passengers, or, for the year, of 1,078,000. Part of that increase was due to the opening of the Dingle Station, at the south end. They carried last year 8,736,000 passengers, the number they carried in the first completed year after the opening of the railway being 5,400,000, so that they had increased by 3,200,000 passengers—a rate of progress in five years which he had no doubt they would consider eminently satisfactory. They had run during the half-year 371,000 miles, against only 320,000 in the corresponding half of last year. They were keeping the expenditure carefully in hand. Their ratio of revenue to expenditure worked out at 64·54 per cent. That might strike them as being rather high, but when they eliminated the amount carried to renewal and contingent funds, and the amount paid to the Tramway Company, neither of which were fair charges upon the traffic, their traffic expenses were reduced to 56 per cent. of the revenue, which he thought was a very reasonable and moderate figure. The expenditure per train mile during the half-year was 15·65d., against 15·67d. in corresponding half of last year. The revenue per train mile was equal to 24·25d., against 23·79d., which was a slight increase. The locomotive expenditure was 3·71d., against 3·68d. per train mile—practically the same. They endeavoured to maintain the efficiency of the line in every way, and it was to-day in better condition from one end to the other than five years ago, when it was opened to the public. The electrical equipment was also maintained in the highest state of efficiency, and though it but cost a little more to revenue, they felt they would be recouped fully by doing so. They had now £10,700 to the credit of the renewal and contingent funds. The traffic upon the south extension was showing a very satisfactory growth. The complaints which had formerly been made as to the lighting of the carriages had received attention, and during the past fortnight the booster they had ordered had come to hand, and would be placed in position at the south end, so that, he was glad to say, the light was now as steady as possible. Their experience of the booster would make them get one for the north end also. All the carriages had now been heated with electric heaters, and were now very comfortable. When it was borne in mind that they only charged 3d. for a journey that would cost 13d. on the London and North-Western Railway, it would be seen that they were doing a great public service.

Mr. Richard Hobson seconded the motion.

The Chairman, replying to Mr. Menzies, who said he did not think a dividend of 3¼ per cent. per annum, was a sufficient rate of progress, said they were paying the dividend this year entirely out of profits. Of course a railway company could not be measured by any industrial concern; it was not expected to pay at any time large dividends. He thought the growth of the line had been very satisfactory. If they had had no payment to make to the tramway company, the dividend would have been perhaps 3¾ per cent. He had no doubt the line would pay a larger dividend in the future.

The motion was then carried unanimously, and it was also agreed to pay the dividends referred to above.

Messrs. Edward Lawrence and G. H. Robertson were re-elected directors.

The Chairman, replying to a vote of thanks to the directors for their services, said he would like to remark upon how much they valued the services of their very excellent engineer and manager, Mr. Cottrell. They were largely indebted to him for his zeal and watchfulness. Very few men in this country had his technical knowledge of electricity, and he had also great tact and organisation in dealing with working men, which were very valuable qualities.

The proceedings then terminated.

The National Telephone Company, Limited.

The report of the directors for the half-year ending December 31st, 1897, to be presented to the shareholders at the twenty-first ordinary general meeting of the company, to be held at the City Terminus Hotel, Cannon Street, London, on Thursday, February 17th, 1898, at 1 o'clock p.m., reads as follows:—

"The income accrued in respect of the business of the half-year amounts to £507,602 17s. 3d., as compared with £439,978 2s. 4d. for the corresponding period of 1896, being an increase of £67,624 14s. 11d. The working expenses for the half-year amount to £283,085 12s. 11d., as compared with £245,278 13s. 9d. for the corresponding period of 1896, being an increase of £37,806 19s. 2d. The net result for the half-year (after deducting the Post Office royalties amounting to £46,059 16s. 8d.) is a profit balance of £178,457 7s. 8d., as compared with £154,982 8s. 4d. for the corresponding period of 1896, being an increase of £23,474 19s. 4d. The rentals carried forward for unexpired terms of running contracts amount to £473,586 17s. 10d., as compared with £414,714 9s. 8d. at the corresponding period of 1896, or an increase of £58,872 8s. 2d.

"Out of the available balance of £156,435 8s. 5d. shown by the net revenue account (No. 3) the board will recommend the payment of a dividend at the rate of 6 per cent. per annum, less income-tax, on the first and second preference shares, 5 per cent. per annum, less income-tax, on the third preference shares, and 6 per cent. per annum, free of income-tax, on the ordinary shares. The board also propose to transfer £40,000 to the reserve fund, and to carry forward the balance of £10,034 3s. 5d.

"Capital Expenditure.—The sum of £267,375 1s. 3d. has been expended on capital account during the half-year, partly in the erection of 5,633 additional exchange and private lines and partly in the construction of underground lines in substitution for overhead wires in several important places. Notably in Manchester, the corporation of that great centre of industry were the first to realise the many advantages to the commercial community to be secured by the concession, upon reasonable terms, of the necessary powers, and as a consequence the entire system of underground mains in that area has been completed. The financial burden cast upon the company is considerable, but the board have faced it in the confident belief that greatly increased efficiency will lead to a corresponding extension of the use of the telephone. Similar concessions having been made by the authorities of Belfast, Birmingham, Blackburn, Bradford, Bristol, Dublin, Dundee, Leeds, Liverpool, Nottingham, Portsmouth, Sheffield, and other leading cities and towns, the underground works in these places are being proceeded with as rapidly as possible. In the interest of the more perfect intercommunication between subscribers in the several localities, which must immediately result from the change of system, it is to be hoped that other important places will speedily follow the enlightened lead of the great telephonic centres above enumerated.

"It having been determined that the valuable services of Mr. Alderman Joseph Thompson could be more advantageously absorbed in a more specific attention to the affairs of the company in Manchester, where he is so generally known and appreciated, he was good enough to undertake those duties, and a vacancy in the board resulted. This has been filled by the election of the Rt. Hon. Sir Henry Hartley Fowler, G.C.S.I., M.P., whose residence in and long connection with the very important telephone area of which Wolverhampton is the centre, appeared to justify his being invited to join the board in the interest alike of the company and the public."

Westminster Electric Supply Corporation, Limited.

The report of the directors states that the business of the corporation continues to make satisfactory progress. The supply of current which, on December 31st, 1896, was provided for the equivalent of 249,318 lamps of 8-C.P., had increased by December 31st, 1897, to the equivalent of 290,561, and at the present time there are on circuit the equivalent of 292,883 lamps of 8-C.P., and applications have been received for a further 10,886. The length of roadway in which mains have been laid now exceeds 44 miles, making about 180 miles of ways, into which upwards of 152 miles of copper (strip and cable) have been drawn.

The extension of the central stations, rendered necessary in consequence of the increase in the business of the Corporation, as reported at the last general meeting, has been proceeding during the year, and the board are glad to be able to report that the additional buildings and plant are now nearly completed. The plant and machinery have been working satisfactorily throughout the year, and have been fully maintained from revenue, and the directors consider that, although the economical working of the stations has been greatly affected by building operations, it is satisfactory to note that there is no increase in the cost per unit generated.

As stated in their last report, the board had approached the holders of the founders' shares, and had agreed with them a scheme for cancelling the founders' shares, but on further consideration it was found that difficulties might arise thereafter, and an amended scheme was proposed, in accordance with resolutions passed at special meetings of the shareholders called for that purpose. Your directors have pleasure in stating that, owing to the way in which they were met by the holders of the founders' shares, those shares have ceased to exist, and all the shareholders are now on the same footing.

The net revenue of the year amounts to £49,461 3s. 10d. An interim dividend, at the rate of 8 per cent. per annum, for the half-year ending June 30th, 1897, has been distributed. The balance to the credit of the account is £34,013 17s. 5d.; the board, therefore, recommend the payment of a dividend at the rate of 16 per cent. per annum, less income-tax, for the past half-year, making 12 per cent. for the year ending December 31st last, carrying forward a balance of £3,119 4s. 1d.

The directors having considered the question of provision of future capital, gave notice to pay off the present mortgage debentures bearing interest at the rate of 5 per cent. and 4½ per cent. per annum on March 1st next, and have created new first mortgage debentures of £250,000, bearing interest at the rate of 3½ per cent. per annum. Of this amount £200,000 has been issued, and after providing for repayment of the old debentures, the balance will be expended in further plant and machinery, and the extension of existing stations. The board much regret that owing to the issue having been subscribed four times, they were unable to make any allotment to a large number of applicants.

Portrush and Giant's Causeway Tramway Company.

The twenty-second ordinary meeting of this company was held on 1st inst. at Portrush. Dr. Anthony Traill presided. After the routine business the directors' report was submitted and adopted. It stated: "Your directors have to report a falling off in the receipts during the past year, as compared with those of the year of 1896. In the passenger traffic there has been a decrease in numbers, the total number being 79,015. This falling off has arisen from the interference of the Board of Trade with our electric traffic, and from the unusual wetness of the summer season."

The Dublin United Tramways Company (1896), Limited.

The report of the directors submitted to the meeting held at the Imperial Hotel, Lower Sackville Street, Dublin. The directors submit the accounts for the half-year ended December 31st, 1897. The receipts amount to £19,250 1s. 6d. from the Dublin United Tramways Company, and £3,581 15s. from the Dublin Southern District Tramways Company, making, with the balance brought from last half-year, and the profit on Bank of Ireland Stock, sold, £23,409 7s. 5d. at credit of revenue account. Deducting mortgage debenture interest, £1,429 9s. 2d., and directors' fees, £450, a sum of £21,529 18s. 3d. will remain available for division. Out of this sum the directors have declared a divided at the rate of 6 per cent. per annum on the preference shares, and at the rate of 4 per cent. per annum on the ordinary shares, leaving a balance of £922 18s. 6d. The section of the Clontarf line from Dollymount to Annesley Bridge has been worked by electricity since November 11th last, with very satisfactory results, and it is expected that within the next few months the electric cars will be running to Nelson's Pillar from Annesley Bridge on the north side, and from Haddington Road (Dalkey line) on the south. The new line connecting Rathmines with Ball's Bringe *viâ* the Appian Way and Pembroke Road, is being constructed. A Bill to permit of increased speed on the Haddington Road and Dalkey line is being promoted by the Dublin Southern District Company, and the directors expect that it will successfully pass through Parliament.

Waterloo and City Railway Company.

Mr. Wyndham S. Portal presided yesterday over the eighth half-yearly meeting of the shareholders of this company held at Waterloo, and in moving the adoption of the report said that the whole of the share capital, £540,000, had now been received, and the total outlay, up to December 31st last, had amounted to £473,776, which included £25,000 for interest paid to the shareholders during the construction of the line. The directors hoped to be able to arrange with the London and South-Western Railway Company for bringing the line into use by the middle or end of next month.

Col. Campbell seconded the motion, and the report was adopted.

The City of London Electric Lighting Company, Limited.—Gross revenue return, quarter ended December 31st, 1897. Gross revenue from sale of current for public lighting (after deduction of allowances), quarter ended December 31st, £3,119; corresponding quarter last year, £2,970. Gross revenue from sale of current for private lighting (after deduction of allowances), &c., quarter ended December 31st, £59,796; corresponding quarter last year, £53,399. Gross revenue from other sources (estimated), quarter ended December 31st, £2,000; corresponding quarter last year, £1,000; total, quarter ended December 31st, £64,915; corresponding quarter last year, £57,369; increase £7,546. Equivalent of 8-C.P. lamps connected on December 31st, 1897, 296,012; increase during quarter, 17,850. Equivalent of 8-C.P. lamps connected on December 31st, 1896, 247,785; increase during corresponding quarter last year, 19,045.

British Electric Traction Company.—The Electric and General Investment Company have offered for subscription a first issue by the British Electric Traction Company, Limited, of 10,000 6 per cent. cumulative preference shares, of £10 each, at £12 10s. per share. The share capital of the latter company is £600,000, in equal proportions of 6 per cent. cumulative preference and ordinary £10 shares, and the undertaking was, the prospectus states, formed in November, 1896, to acquire the business of the British Electric Traction (Pioneer) Company, and to develop electric traction in the United Kingdom and elsewhere. It is pointed out that all the ordinary shares (30,000) have been subscribed and paid up in full, and that applications from holders of these for the present issue will be preferentially considered. The subscription list opened on Tuesday, and was to close yesterday.

The Edison and Swan United Electric Light Company, Limited.—The directors have resolved that a payment on account of the dividend of the current year be made at the rate of 5 per cent. per annum, less income-tax, on the "A" shares of the company, in respect of the half-year ended December 31st, 1897. This will work out at 1s. 6d. per share on the partly paid £5 shares £3 paid, and 2s. 6d. per share on the fully-paid £5 shares, less income-tax. The payment will be made upon the register as it stands this day, and the dividend warrants will be issued on the 24th inst.

W. T. Henley's Telegraph Works Company, Limited.—The directors have resolved to recommend a dividend at the rate of 12 per cent. per annum on the ordinary shares, including the interim dividend of 3 per cent. paid in September.

Metropolitan Electric Supply Company, Limited.—A meeting of the holders of founders' shares of this company was held at Winchester House on Tuesday, but our representative was informed that the meeting was private.

Stock Exchange Notices.—The committee have ordered to be quoted in the Official List:—Direct West India Cable Company, Limited—£120,000 4½ per cent. registered debentures, Nos. 1 to 1,200.

Telegraph Construction and Maintenance.—The directors announce a further dividend of 10 per cent., making 15 per per cent. for the year 1897.

TRAFFIC RECEIPTS

The City and South London Railway Company. The receipts for the week ending February 6th, 1898, were £1,068; week ending February 7th, 1897, £1,128; decrease £60; total receipts for half-year, 1898, £6,456; corresponding period, 1897, £6,611; decrease, £155.

The Liverpool Overhead Railway Company. The receipts for the week ending February 6th, 1898, amounted to £1,283; corresponding week last year, £1,241; increase, £42.

The Western and Brazilian Telegraph Company, Limited. The receipts for the week ending February 4th, 1898, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company. Limited, were £2,856.

THE WATT ANNIVERSARY.

At the recent James Watt anniversary dinner of the Institution of Engineers and Shipbuilders in Scotland, Lord Kelvin proposed "The Memory of James Watt" in the following terms:—He had, he said, to thank them for their kindness in allowing him to propose the toast on this great occasion. They had referred to the connection of James Watt with the University of Glasgow. In the apparatus room of the Natural Philosophy Class there now was, he might remind them, the model which Watt was employed by the University to repair in some minor details, when, in considering it, he saw not only what should be repaired, but some of the defects of the principles which it realised, and was led on from that small beginning to the great work which they were met to commemorate. The 19th century, in the eyes of engineers—and if in the eyes of engineers, then in the eyes of the whole world—was the century of James Watt. There were engineers before James Watt. Happier than the men who lived before Agamemnon, their memory was not lost in obscurity for want of the sacred bard and prophet and historian to commemorate their deeds. Tubal Cain was a great mechanical engineer, whose name was a household word in Scotland in the end of the 19th century. Poets and historians had chronicled the works of Archimedes. Skipping 10 centuries, or rather skipping 20 centuries, we came to Smeaton, the man who led up towards the mechanical developments which Watt perfected. Of all the 60 centuries of recorded human history no century had been so great as the 19th in engineering, in the work of applying the laws of matter, and the principles of science for the benefit of mankind. We almost forgot there was engineering before this century. Steam navigation came into existence at Dalswinton Loch, in the East of Scotland, and Symington's boats, after their first trial in 1798, were placed a few years later on the Forth and Clyde Canal. That was the beginning of marine engineering, and what was marine engineering now? It had covered the whole ocean with the works of English engineers. By England he meant—he always meant—England, Scotland, Ireland, India, Canada, and all the other British colonies. Engineers counted other names along with the name of James Watt as being noteworthy in the annals of the 19th century—the names of Faraday and Carnot and Joule. These had all done great things to make the latter end of the 19th century worthy of its beginning with James Watt. The steam engine of James Watt and of the 19th century, was it to be the engine also of future centuries? The latter part of the 19th century opened up new vistas in the application of the works of science, led up to by Watt, and Carnot, and Regnault, and Joule. No man would have been readier than Watt to see the possibilites of other means of producing power than steam. Steam, electricity, and the means of development on which electricity depended would, he was sure, have engaged his attention and admiration, and he would have worked for the promotion of anything that could improve the steam engine. He (Lord Kelvin) believed that we should have ships driven by steam power for at least 100 years yet. We might safely say, so long as our coal supply lasted—a good many hundred years—steam power would keep alive directly the results of the labours of James Watt. He would not prophesy that in any respect, even for land use, other agents would supersede steam, or that the 20th century would be the century of oil and gas and internal combustion engines. Engineers, however, should be interested in the question—"Was the internal combustion engine going to supersede the steam engine?" Whether it did so or not, for any larger application than we now had the gas engine, we should have no less reason to be grateful to James Watt. At the end of the 20th century his name would, he believed, be received with as much respect and gratitude as it now was. In pure science Watt was a leader. He (Lord Kelvin) remembered that his great master in physical science, Regnault, had "la loi de Watt," the law of Watt, with relation to the latent heat of steam always upon his lips. It was a matter of great joy and perpetual pleasure to the University of Glasgow that it had had the honour of having given Watt encouragement in the early days of his studies, and that in his workshop at the University, the Scientific Society, the Philosophical Society, and the Physical Society came into existence. These had been the parents of many similar societies all over the British dominions, with what tremendous benefits to mankind they all knew. Let them think of living now as compared with living 100 years ago. Some people asked, were we happier or better by reason of these wonderful inventions and discoveries? People, he might reply, were happy and good, and sometimes neither happy nor good, during the 60 centuries that preceded James Watt. But we had social advantages now that no human being had before 1800—the advantage, for one thing, of being kept continually in touch with our friends. Engineers did not look upon the application of their craft merely from a mechanical point of view. They knew that their steamers and railways were of great direct benefit to humanity. He had in his pocket a telegram from

India describing the recent eclipse. It read—"Eclipse well seen, also red flames and Baily's beads. Some very fair photographs. The whole party well satisfied." The message reached him the forenoon of that day. The writer, a man 80 years of age, went all the way to India to see the eclipse, and to try to contribute something to the knowledge to be obtained from it. The telegraph, some might say, was not one of the benefits derived from James Watt's labours. He said it was, because without the marine engine and steam navigation they could never have had the ocean telegraph, which in itself was a great blessing to the world. The world to-day was happier and better in every respect for the work of James Watt, and he asked them all to receive with due honour the toast of his memory.

THE PACIFIC CABLE.

(*Concluded from page* 164.)

The Eastern Extension Company represents a combination of associated companies engaged in telegraph transmission between England and Australasia. The lines of the company comprise those of three amalgamated companies:

1. The "British Indian Extension," from Madras to Singapore, with a share capital of £460,000.

2. The "British Australian," from Singapore to Australia, with a share capital of £540,000.

3. The "China Submarine," from Singapore to Hong Kong and Shanghai, with a share capital of £525,000.

The combined share capital of these three companies amounted to £1,525,000. On their amalgamation the united share capital, by a well-known process of "watering" to the extent of £472,500, was increased nominally to £1,997,500. The united company, since known as the Eastern Extension Australasia and China Telegraph Company, Limited, has been exceedingly prosperous; it has paid 7 per cent. on the enlarged capital, equal to 9 per cent. on the original capital. An examination of the published statement establishes that it has in addition expended out of the profits earned, no less a sum than £1,571,540 on extensions and other productive works, and there remains unexpended and undivided to-day a reserve of surplus profits amounting to £804,193.

These figures establish that the Eastern Extension Company has become a remarkably profitable investment. It regularly pays good dividends, but the dividends are no guide to the profits made. It holds in reserve undivided profits far exceeding in amount the whole value of its cables between Asia and Australia. The accounts of the company for 1896 and the first half of 1897 show that the net profits actually earned during these periods amounted to 13 per cent. on the present capital, and 17 per cent. on the capital prior to its being watered.

The company is unwilling to have this state of affairs changed. They know perfectly well that the telegraphic traffic is steadily increasing, and that as the traffic grows the profits will become still greater. It is easy, therefore, to understand why the company has never viewed with friendly feeling the proposed Pacific cable. Its managers are not willing to divide the business with the new line. They must retain it entirely in their possession. They have secured a rich monopoly, and their desire is to make it even more profitable, and to strengthen and perpetuate it.

The Pacific cable has been projected in no spirit of hostility to any company or to any country. It has been advocated as a means of extending to the whole Empire the advantages derivable from the geographical position of the Dominion. Canada offers the connecting link in an Imperial chain of telegraphs encircling the globe. When the project is completed, it will bring the mother country into direct electrical connection with every one of the great possessions of the crown in both hemispheres, without touching the soil of any foreign power. Thus it cannot fail, in a high degree, to promote Imperial unity. Indeed, it is difficult to conceive how a perfect union, or any union of the whole, is possible without union between the parts. The whole Empire is in strong sympathy with the aims and aspirations which a few years back were limited to a few men of advanced thought. The historical event of last June has shown to the world that "the British people are one people, animated by one spirit." It is recognised that we are approaching the period when new relations may be established between the United Kingdom and those younger British communities beyond the seas, known in past history as colonies, but which are passing from colonial tutelage to a higher national status. In order to promote these closer relations, what is more desirable, what more necessary, than that each and all be connected by the appliances which art and science have devised? Canada stands first among the British communities of the outer Empire. Scarcely second to Canada we look forward, in no long period, to welcome the kindred Dominion of Australia, comprising under one federal government half a dozen colonies, each possessing great potentialities. What more in harmony with the spirit of the British people than that Canada and Australia be brought in close communion? Is it not indispensable to vital public interest that those two great units of the Empire—the island continent in the South Pacific and British North America, should possess the means of instantaneous communication, one with the other?

The proposition of the Eastern Extension Company submitted to the Conference of Premiers has no such purpose in view. Its object is indeed the very opposite. While the consolidation of the Empire *demands that* the Queen's subjects in Canada and Australasia shall *possess all the* advantages which the closest telegraphic connection can effect, the policy which animates that company would cause these communities to remain severed. Is such a policy to be commended? Does not the Eastern Extension Company when persistently exercising its manifold and widely ramified influence to keep Canada and Australia disunited, assume an attitude of hostility to both countries and to Imperial unity?

In the interests of the Eastern Extension Company the Pacific cable has been declared to be impracticable; its cost has been greatly exaggerated; it has been denounced as a work which could not be maintained without burdensome subsidies; it has been stigmatised as inimical to telegraphy and trade; and it has been decried and misrepresented in every possible manner. The explanation is to be found in the fact that the company is unwilling to relinquish its monopoly and to rest satisfied in the future with a reasonable return for capital invested. On this point the writer is tempted to quote a single paragraph from his address at the Colonial Conference of 1894 as given in the proceedings (page 85).

"The progress and well-being of Canada, Australasia, and the Empire cannot be retarded in order that the lucrative business of a private company may remain without change. Even if the chairman of the Eastern Extension Company succeeded in converting us to his commercial ethics, that the profits of the monopoly he represents must be maintained inviolate, it does not follow that the project of a Pacific cable would not be carried out in some form, even if Canada and Australasia abandon it. There are indeed unmistakable signs that a Pacific cable may shortly be carried out by France and the United States. We all know that France has already completed a section of 800 miles at the southern end, and the United States has recently expended $25,000 in making an elaborate survey of about one-third the whole distance from San Francisco (to the Hawaiian Islands.) With a rival line in foreign hands, it is easy to see that the Eastern Extension would gain nothing, while the Empire would lose much."

With respect to the objections raised by the Eastern Extension Company, they have been completely refuted. The very best evidence shows beyond all question that the project is perfectly feasible, that the cable should be established as a State work, that, so established, the revenue from business obtainable will be ample to meet every charge, including working expenses, maintenance, renewal, interest on cost and sinking fund to replace capital; that in fact, the cable can be established in the most satisfactory manner, and that all its advantages can be attained without any cost whatever to the taxpayer. That the prospects are of this character is attributable to these facts, viz.:

1. As a State work, the capital employed would be obtained at the lowest possible rate of interest.

2. The capital would be limited to the necessities of actual expenditure in establishing the work; there would be no possibility of enlarging the capital account by adding "promotion expenses" or by "watering stock" in any form.

3. No dividend would require to be declared, or bonus paid. Revenue would only have to meet ordinary charges, including interest on the actual cost at a low rate, possibly $2\frac{1}{2}$ per cent.

4. Remunerative traffic which would be controlled by the Australasian Government already exists.

5. Such traffic is continually growing, and it is difficult to assign a limit to its growth.

6. The facilities created and the reduced charges would open up a new and profitable business across the Pacific which would be subject to the new line.

Such being the case, the question may be asked, is there any reason other than the opposition of the Eastern Extension Company why the establishment of this important national work should be farther delayed? It must be admitted that the Pacific cable in operation would put an end to the monopoly of the Eastern Extension Company and diminish the immense profits it enjoys. As, however, less than half the whole traffic would prove remunerative to the Pacific cable, there would remain ample business to the company to yield a good return for the capital invested.

In the memorandum laid before the House of Commons last July by the Secretary of State for the Colonies, it is distinctly indicated that, while the Home Government is willing to co-operate with Canada and the Australian Colonies, the Imperial authorities are unable to see the way to take the initiative, and that they "now await definite proposals from the Colonies interested before proceeding further in the matter." It unfortunately happens that the Australasian Colonies remain under the disadvantage of being disunited politically, and they are not all equally in favour of the Pacific cable, Western Australia and South Australia being somewhat in sympathy with the Eastern Extension Company. New Zealand, New South Wales, Queensland and Victoria desire to have the cable laid on the Canadian route. As the traffic to make it a profitable undertaking would have its source chiefly in these colonies, and, moreover, the land lines within each colony are owned by each respective Government, they have it in their power to control the trans-Pacific telegraphic traffic to the extent required to make the cable a profitable undertaking.

At this distance it is not easy to understand why these four colonies do not agree to take some definite line of action. It is now close on six months since the Premiers met in London, and, as far as known, they have not seen their way to agree on any joint proposal, owing, doubtless, to unexplained local difficulties.

Under these circumstances it is not improper to consider if there be any duty or obligation resting on us in Canada. The Dominion is now looked up to as the elder brother in the British family of kindred nationalities. If, as Canadians, we have faith in our destiny as no inconsiderable element of the great Empire, are we not called upon again to take the initiative? The mother country awaits a proposal. It cannot well come from disunited Australasia. If we are to be brought within speaking distance of the kindred communities in the southern seas, the first impulse must come from ourselves. Shall the opportunity which circumstances have presented be seized, and another proof given to the world that "Canadian Government and people are determined, in all ways, to promote Imperial unity?"

SANDFORD FLEMING.

A SURVEY OF THE POSSIBILITIES OF ELECTRIC HEATING AND COOKING.*

By W. P. ADAMS, A.K.C., A.I.E.E.

(*Concluded from page* 163.)

THERE is one direction in which one might anticipate a large development of electric cooking, and that is in flats. If architects will arrange for a general hot-water supply for the whole building, as I believe is now done in many cases, electric cooking presents such an advantage that an important movement in this direction should take place when the supply companies are convinced of the advantage of charging such prices as will be generally acceptable. I think I have said sufficient to indicate that even with electricity at 3d. per unit, electric cooking is not extravagantly expensive, and if its other great advantages are taken into consideration, particularly the economical results from the perfection of the cooking, it ought to be received with prompt favour.

I am hoping that before long those responsible for electricity supply will begin to make a definite move in the development of electric heating and cooking. It is not sufficient to merely reduce the price of electricity to a reasonable figure, as many of the Corporations have already done, but steps should be taken to induce people to become users of electricity for other purposes than lighting. The hire system, which the gas companies are much in favour of, should be adopted where possible. One of the difficulties which has been met with in the attempt to develop electric heating is the high first cost of the apparatus. This is largely owing to the comparatively small output of heating apparatus at the present time, and is also owing in no small degree to the many different voltages which the goods have to be made up for. You will probably be surprised to learn that there are no less than 14 different voltages in general use at the present time, and you will quite appreciate that this does not tend towards the cheapening of the appliances.

I have little doubt, if supply companies are prepared to give this matter their careful attention, that mutually satisfactory arrangements might be come to between themselves and manufacturing firms so as to meet these difficulties.

I have now to consider the practicability of using cooking and heating plant in connection with plant installed for lighting residences and factories.

In very few and well-arranged and properly-managed private installations does the cost exceed 4d. per unit, and in residences where accumulators are used it would simply mean running the plant a few hours a day extra if electric cooking apparatus were adopted.

In factories where large electric lighting plants are in use, the same argument holds good. The probability is that the generating engines are supplied with steam from the main boiler system, and the man in attendance on the general machinery is expected to look after the electric lighting plant. The cost of generating electricity during the daytime for cooking meals for the staff of this establishment, and perhaps for the employés, is, in such a case, almost a negligible quantity.

I must here make a small digression to call your attention to the curious ideas some people hold with regard to electric cooking. An establishment in Liverpool has just installed a large and economical plant for electric lighting purposes, and it had been proposed to the owners that they should use it during the daytime for cooking purposes. I was asked by the electric light contractors to loan some apparatus for testing, and the conditions being distinctly favourable, this was done. A little later I was informed that the committee would not adopt electric cooking. I was anxious that the test should have been made under my supervision, but it was not thought necessary for me to be present. Inquiries were made, and I found that the committee itself had superintended the experiments, and had insisted upon the food being placed on the appliances before current was turned on. As one of the elementary rules of cooking is that the apparatus should be heated up to the proper temperature before the food is placed upon it, you will understand that such an experiment was foredoomed to failure. I relate this instance as an illustration of the common idea that electric cooking apparatus is capable of doing things which no one would think of expecting from ordinary cooking apparatus, and simply for the reason that the word "electric" is used in connection therewith. Every electrical engineer, at one time or another, has met with peculiar ideas of this sort.

There is nothing, of course, nothing magic about electric heating and cooking appliances. The advantages which we claim for them are: (1) That they are more economical in point of heat utilised than any other appliances; (2) that they are quite without equal in point of cleanliness and general convenience; (3) that there is practically no waste of material in the cooking; (4) that by their means cooking is reduced to a simple science, and absolutely uniform results can be obtained, this being due to the ease with which the heating effect is controlled by switching. In the oven it is usual to fix a thermometer, indicating on a dial on the front of the door, and given temperatures can be maintained within a few degrees. I might further claim that such appliances are perfectly free from such dangers as attend the use of gas cookers. Explosions are impossible, and the risk of fire is nil.

I must now beg of you to spare me a few minutes for the consideration of electric heating by radiators.

I have already indicated at the commencement of this paper that this subject requires consideration from quite a different point of view to electric cooking. Assuming for the moment that there is likely to be any large development, you will at once observe that this will bring no load to the stations during the summer time, and, owing to the large amount of current the radiators consume, they will make the winter load heavy. It may be that persons who adopt electric cooking may be inclined to use the apparatus during the summer time only, on account of its coolness, in the same way as people now adopt gas ovens, returning to the use of the kitchen range in winter. If this were done to any large extent it would probably meet the difficulty, and it might even be desirable for supply companies to give special terms for the use of electric cooking appliances in summer, and increase these charges during the winter. Whether such a plan is feasible or not will have to be ascertained as the problem develops.

When estimating roughly what current radiators are to be wound for, for a given space, I generally assume that 500 watts will be necessary per 1,000 cubic feet of space, in the coldest weather. This, of course, is only a very rough guide, and in every case the general conditions must be taken into consideration. In my office in the City, which has a capacity of 2,000 cubic feet, with one outside wall almost entirely consisting of window space, I rarely use a larger radiator than one absorbing 600 watts. In very sharp weather I have found it necessary to put two of these on for the earlier part of the morning, and sometimes on Mondays, after a continued frost extending over Saturday and Sunday. In this instance it will be seen that a less quantity is required than 500 watts per 1,000 cubic feet of space. In the case of a building with several thin outside walls, and other unfavourable conditions, probably more than the 500 watts would have to be provided for.

With radiators consuming this amount of energy you will appreciate that electric heating is not likely to receive much support when such charges as 8d. per unit are made. At the beginning of last year I was requested by an architect to fit nine radiators in a spacious office in the city. The firm was a wealthy one, and expense was not considered an important matter owing to the convenience of the electric radiators. I pointed out before the order was placed that the cost of current would probably be very high; but, notwithstanding my warning, it was decided to have the radiators fixed. After they had been running for three or four months I was informed that the cost was so excessive that their use would have to be discontinued. With one or two small exceptions these are the only radiators ever installed in the city of London; and, while the prices are maintained at the present figure, little development is likely to take place; and yet the City is an almost ideal place for the use of electric radiators, owing to the fact that the bulk of the offices close at an early hour, and that the occupiers are willing to pay a good price for so convenient and sanitary means of heating as electric radiators provide.

Experience shows that even at so high a figure as 3d. or 4d. there is considerable demand for electric radiators, and this is not surprising when one considers that the heat produced is of exactly the quality that one could desire. It is not sufficiently high to deprive the air of its moisture. There are no products of combustion to vitiate the atmosphere, and the radiators are turned on and off with the same ease as the electric light.

I cannot now make detailed mention of the smaller heating appliances, but I think that their employment is one worthy of some consideration by supply companies. If they are at all largely adopted, they would be of value in increasing the day load, and it is likely that they would be employed at times when the cooking apparatus would not be in use. Take, for instance, the electric kettle. Each kettle takes from 300 to 500 watts, and they are mainly used for preparing tea in the afternoon. It is conceivable that, if used in large numbers, they would help to fill up the somewhat awkward dip in the curve occurring about 3 or 4 o'clock in the afternoon, after the hot cupboards and plates had gone out of use.

In conclusion, I will ask you to be as lenient as possible when passing judgment upon this paper. I am well aware that I have been guilty of some temerity in venturing to read a paper upon a subject about which there is so little practical knowledge. My excuse for doing so is, that I believe there is a reasonable probability of considerable development in this direction in the near future; and I hope that the figures which I have placed before you may help electrical engineers and others interested to understand better the claims that this branch of electrical engineering has upon them. I have attempted to deal with the problem as widely as possible, and I hope that the aspect of affairs from the central station engineers' point of view may receive some consideration during the discussion.

* Abstract of paper read before the Northern Society of Electrical Engineers.

ELECTRICITY IN THE MACHINE SHOP.

THE severity of misfortunes is often mitigated by subsequent benefits arising, which are the better available because of the very conditions caused by misfortune. As an example of this, which the near future is placing to the hand of English manufacturing engineers, we may name the engineers' strike, and the tactics which led up to it. We have pointed out that the restrictive action of trades unionism has been responsible for the continuance in use of thousands of old-fashioned tools, which their owners are perfectly well aware could be economically replaced by new and improved tools of greater output *capacity*, and doubtless this would be done if only such new tools were allowed to work at their proper speeds. American visitors, never at a loss to cast a sneer at English shops, have not failed to note the slow speeds at which tools are driven in union-ridden shops, while perhaps themselves subscribers to the American fund which is being raised to maintain restricted output. As we may hope the near future will see an entire change in English shop management and tool using, it is reasonable to anticipate that there will be a very large demand for new machine tools, and it seems opportune that we should endeavour at this probable crisis to draw attention to the very great economy of electrical driving of machine tools, and to the extreme desirableness of entirely changing the practice as regards machine tools. To some extent in this country, but to a much greater extent in America, the driving of tools electrically has made rapid progress since the year 1894. Modern American shops fitted with new tools have found to some extent that the application of the new motive power transmission has not been possible to be carried to its most economical extent, and to the larger tools there has been required a good deal of extra fittings, while smaller tools have been banked, as it were, upon an electrically-driven shaft, that would have been better driven independently. In fine, electricity has been rather a graft upon an already grown tree than a naturally grown branch. Could we see 20 years ahead, it is probable that a continuance along the lines now opening out would carry us to the time when the demand for small motors would have been met by their supply, and that machines driven by shafting will be almost, or wholly, superseded by machines with their own motor, just as large machines have now their own separate motor. Further, we think the future will see a very great change in tools themselves. There will be more portable tools carried about by overhead cranes and attached to the work, in place of, as now, work being taken to fixed tools. One of the complaints against trade unionism is, that under its rules one man must attend to one tool only. Machine tools seem to be now working under parallel conditions. One piece of work can only be operated upon by one tool at a time. An example of how electricity will change this is to be seen in an illustration of the drilling of a large casting in the shops of the General Electric Company, at Schenectady. The cumbersome casting is hung up in chains to be drilled by a radial drill, which is perhaps about the first step in the carrying of a machine tool to its work, and has made the radial drill so popular and successful. On another page (*Cassier's Magazine*) the same casting is shown lying safely on the floor and being operated on by two portable slotters and a portable drill, all electrically operated. In present practice, or shall we say old practice, huge machines are required even to drill small holes if the piece drilled is large. The size of machine tools has in fact been measured by the bulkiness of the things being made. There is no reason whatever that a ½-inch drill should be carried by a 2-ton frame. Carry the drilling machine to the work and at once the tool is reduced to what is necessary to drive the ½-inch drill. Machine tools will be small and portable. They can be attached by the half-dozen to a big casting, and work in future will be dumped down at a convenient place in the shop, where it will remain till finished. The lathe and the large planing machine may perhaps still remain fixtures, and have work brought to them, but drills, cylinder boring bars, slotters and shapers will be smaller than of old, and will be portable, and as, perforce, they will require to be separately driven, the small motor is bound to make its appearance.

How does all this bear upon our prefatorial remarks? Simply that the impending change of practice with its consequential demand for new tools will or should be made coincident with the new system of driving, and the new tools ought to be fitted to serve the new driving arrangements.

The economy of electrical driving arises largely from the abolition of shafting, steam piping, &c., and the concentration of steam plant at a centre. It does not necessarily follow that the total abolition of all intermediate gearing between the motor and the actual tool can be effected economically, and, in drawing attention to this point we might quote Mr. Mullin, to whose article we have referred, to the effect that two notable instances of direct-driving have signally failed, and been replaced by gearing, in one case, at least, of a comparatively discredited variety. One is that of the geared trolley motor which replaced the direct torque armatured axle. The other case is the bicycle, the high direct-driven machine being entirely displaced by the chain-geared safety, the serious disadvantages of the chain being partially eliminated by the dust-proof case and partially overlooked in the desire to bring the C.G. of the loaded machine further behind the point of support than possible in the high machine. But the use of gearing is essential to small and light motors, and is likely to continue.

It would be well that our manufacturing engineers should very seriously consider the system of electric driving, and the various changes it makes possible before re-organising their shops. Machine tool makers also should be prepared to meet the new demand which is likely to be made upon them. If our views be correct we may say that the harassing tactics of trades unionism have delayed the improvement of our workshops until the improvement can be made wholesale and thoroughly—men, methods, machines and motors all moving together. There has got to be a change, and when it does come it will be thorough, as customary in England, where we are apt to stick a long time in our grooves, but when we do leave them we are thorough.

In America, to judge from Mr. Mullin's illustrations, electrical driving has been largely adopted to old machines as well as applied to new ones, and the result is very mixed, the motors often having a temporary appearance; but there is apparently a strong desire to secure the new driving at any cost, so great are its advantages, and in one large shop it is said that 4,000 hands are now doing the work of 6,000, and with an increased output of 60 per cent. This is a rail rolling mill which has utilised mechanical power to the utmost. Need we wonder that America is now sending rails abroad, and, no doubt, finding such work as will more than provide for the 2,000 hands above thrown out.

We need hardly point out that the saving effected in the size of the bulk of tools, and the reduced dimensions of the buildings necessary to contain them, as well as the lighter construction possible will, in the case of a new works, probably outweigh the cost of the electric motors, and all this saving would be additional to that of the motive power, of oil, belting, and attendance. The modern engineers' shop should, in fact, be simply an area commanded by a traveller arranged to convey the pieces of work to the heavy tools, and to carry the lighter tools to the work. The motive power would be placed anywhere most convenient. In fact, the motive power would usually be placed near the forge, so as to be convenient for supplying steam to the hammer. All driving would be electrical, and warming would be done by steam. When not in use, the portable machine tools would be stacked in close array, not filling much space. Machine tools would be much more saleable than they are to-day, and it would be possible to borrow tools to tide over any special push of work. This cannot be done where tools are bedded down and belt driven.

TECHNICAL LITIGATION AND THE QUESTION OF GOOD WORK IN HOUSE WIRING.

By V. ZINGLER, A.I.E.E.

(*Concluded from page* 103.)

We may now turn to the second subject of the title, which has only been introduced here because, in the case referred to, it was made a position of by the defendants; but, owing to a weak point in their defence, they were driven out of it, and the battle was decided on lower ground. It is, of course, almost impossible to standardise the quality of work that is done in house wiring; fire insurance offices have attempted it; the Institution of Electrical Engineers have drawn up rules to be observed; every supply company has regulations which must be complied with; consulting engineers draw up elaborate specifications; and even wiring firms themselves make out their own specifications, without which the average customer forms a poor opinion of them. And what does it all come to? Can each and every one of these bodies have a representative continually on the spot to see that their rules are observed? If not, with whom does it primarily rest to carry out, if not every rule that has been made, at least such an average standard of work as shall meet the requirements of all the parties concerned? There is no doubt it lies with the firm itself; it is a question of commercial morality and nothing further. The quality of material supplied, the honesty of the foreman, the training of efficient workmen, and the adoption of a proper system of work and of superintendence are all factors in the respectability and standing of the firm; and indicate whether their policy is to be one of getting work at all costs, or of combining the making of a fair profit with work which is a credit to themselves, and studies their customers. It is impossible for the foreman to be honest if he sees that his firm is supplying inferior material, and deceiving the customer; it is still less possible for the workman, who takes his cue from his foreman and the general style of the firm, to avoid scamping his work. He wants looking after enough in most cases, but he is also only human, and endeavours to do his best to please his present masters. And so, when he finds that it is a "nigger driving" concern, and that he is expected to get through the work quickly, with no question as to what lies underneath, why he does it. Firms of this sort are unfortunately very common; it is only necessary to look at the comparative list of tenders often appearing in this Journal to see the great and perfectly unintelligible variations in estimates; these show the electrical trade parasites, the firms whose life may be described as a constant harmonic motion between business or partnership notices and liquidation notices. At the end of each period there is a re-incarnation consisting of a new combination of sells (the pun may be pardoned), and during their short life they manage to do a certain amount of bad work, which also lies dormant for a time, but which, on the application of 220 volts or a little moisture, comes forth from all corners to annoy the customer. Turning to the estimates above referred to, it may be asked why it is that these differ so very much. We have said that this is unintelligible, but this is really only so on the face of it. Let us analyse an estimate. It consists of three parts: material, labour, and contingencies. Now, when quoting to a specification with schedule of lights, the material is a fixed quantity, and its cost may be said not to vary more than about 10 per cent.—speaking only of wiring material, and not plant. It is, of course, possible that some firms do not take as much trouble as others in measuring up for wire and casing, but even this does not make a large difference. It is on the question of labour and contingencies that firms go wrong. Only those who have had plenty of experience in all kinds of wiring work, and lived through it, know how great the uncertainty of time and labour is; building not finished, fittings not ready, unexpected surprises in the way of girders, floors, and walls. These and many other things have to be allowed for if the firm is going to make a profit, or if they are not going to scamp the work. And if these things have not been allowed for in the desire to obtain an order, and are met with when the job is under way, the temptation to try and make the cost keep below the tendered price is no doubt very great. In confirmation of these views, it may always be observed in reading through a list of wiring tenders, that the best-known (and, of course, most experienced) firms are at the top. And it will be found that the firms who do the best work are those who, to begin with, have a conscience; who set about a job with the idea of providing the best material and labour at a fair profit; who do not persuade their customers to take what will not be necessary for their requirements; who have honest foremen and a good system of superintendence; and who have a standard of wiring work from which they refuse to deviate, and to which they have trained a few good wiremen whom they keep. These may be said to be the ethics of the wiring question, and they may be summed up in a remark frequently made by a firm (who conforms to them) when a customer asks, "What will it cost?" "My dear Sir, you can get it done for anything you like!"

It may now not be inappropriate to discuss the various details of wiring work in which the question of good work arises, and especially those which came before the Court in the case we have in view. On this occasion a great deal of nonsense was talked about the "tree" and the "sub-circuit" systems. Because one witness had said that the latter system was the most recent of the two, counsel fell upon it, and dubbed it the "new" system; and this was so insisted on, that there is no doubt that in the mind of the jury it was clear that the plaintiff had not put in this system because he had only himself just heard of it. As a matter of fact, it may be said to be many years old and to be the result of the excellent fire insurance rules which tended to put electrical wiring into something like shape. The "tree" system is certainly antiquated, but there are occasions when it must be used, such as in the wiring of long, straggling sheds with few lights in each. It is even then necessary to fuse each main at every point where it is reduced in section, and also to fuse each light separately. Any failure to comply with this is not only bad work but gross negligence and carelessness. As regards the "sub-circuit" system, this is the only system now used for good house wiring, and on the double-wire system it cannot be said to be complete, safe, or good work unless it consists of D.P. fuse and switch for mains, distributing board with D.P. fuse and switch on each circuit, and fuse board at the end of each circuit provided with D.P. fuse for every sub-circuit, to consist of not more than seven 16-C.P. lamps on each. It is not the object of this article to draw up a specification; but it may be added, without going into the question of material of floor boards, that the poles should be kept apart by an air-space, and that all holes for fixing screws should be well bushed. The failure to do this is a frequent cause of leakage, which leads to other things.

Another point discussed in the case was that of "dry joints." How such a term has ever arisen it is impossible to say, as it cannot be too strongly pointed out that such a thing as is understood by "dry joint" should never have existed, not even on temporary work. It may be said to be an aggravated form of *the* only danger of fire in electric wiring, namely, increase of resistance, and consequently of heat, due to the interposition of a section of lower conductivity, without a fuse to protect it. How any man calling himself an electrician, much less an expert, can go into the witness box and say that there is no harm in a dry joint, passeth understanding. He might, with equal assurance, describe himself as a truthful man.

We next come to the question of casing and bunching of wires. Here experts may even be allowed to differ, as the arguments *pro* and *con* have equal reason. In pipes, where wires must be bunched, the only dangers are caused by bad work; *i.e.*, burrs which may tear the wire, or bad wire which may break down. In either case an arc may be formed, but if the general insulation from earth is good, and the circuits are properly fused, this will not occur. The remedy is to avoid these causes. But as regards wood casing, there are dangers from other causes; *i.e.*, rodents, water and mechanical injury. The use of wood casing is only a temporary remedy against all three. The best remedy against water is to use good wire, and the only remedy against all three is not to use the casing but iron pipe. It may, however, be said that if casing has to be used, it must be used everywhere, if only for the sake of tidiness, and if it is omitted under the floor boards it may also be omitted on the walls. But in the latter case the customer sees it, and in the former case he does not. The conclusion is obvious if good work has to be done.

The only remaining important point is the wiring and fixing of fittings. More bad work may be done at this point than anywhere else on the installation. There is a common belief amongst careless wiremen that there should be a joint for every fitting. Every joint is an increased weakness to the system, and may be likened to the weakest link of a chain—the strength of the chain. But two bad joints are worse than one weak link, as they double the leakage and the source of danger.

In the case of most ordinary plain fittings, such as brackets, tube-pendants, &c., the wires should be left long enough to run right into the lampholder, with a little to spare; this should be coiled up in the back-plate or in the floor above. There are, however, some fittings, designed by artists, and not engineers, where no proper provision is made for wiring. In these cases flexible wire has to be used—that is, while people will buy such fittings—and not only is it customary to make joints here, but the flexible wire is twisted about outside the fittings and bound round by wire without any regard for possible consequences. What is more, the wire used is frequently not vulcanised, also to economise space. The dangers are self-apparent. The remedies are—not to buy badly designed fittings, or to have them altered if necessary; if the fittings must be wired with flexible wire, let it be vulcanised, and fix a small china cut-out in the wall behind or above (as the case may be) the fitting back-plate.

If even this is impossible, and it is necessary to make a joint, the flexible wire at the point of jointing should be strengthened by winding the fine wires round a piece of copper wire of equal section to the circuit wire; the whole should then be soldered together, and well protected.

No flexible wires should pass through metallic back-plates or other metal parts without an insulating bush. In fact, such a thing can only be the result of accident or ignorance. The question of wiring of fittings was fully dealt with by the writer in this Journal some time back.

It is, however, clear that the trouble of fitting joints will always exist more or less until some manufacturer of fittings, more energetic than the rest, will devise and standardise a complete system of male and female sockets for fittings; the male to be in the back-plate and to be wired to the lampholder; the female socket to be fixed as a "point" on the wall or ceiling, and wired back to the fuseboard. The fitting would then make electrical contact just like an ordinary plug and shoe, and it would be secured to the wall by the usual method now employed.

The slight extra cost of these sockets would be met by a more than corresponding reduction in labour of fixing and making joints, not to speak of the convenience of being able to change the fitting if desired. Such a system should commend itself to ladies, who, according to the plaintiffs' experience in this case (and the experience of most other electricians) are never satisfied with a fitting when it is fixed up. The best way to deal with such people is not to make dry joints, so as to lessen the trouble of taking down the fitting next time, but to provide the wireman with a book of order forms to be signed by their customer or his wife whenever an extra of this sort is required, and to charge these up at the end. It will be found an excellent method for suppressing the lady's enthusiasm for changing fittings.

Finally, it is of no use abusing Fire Insurance and Supply Companies' Rules unless something better can be suggested, and if both are adhered to as far as possible, with a due feeling of responsibility and interest in the work, and a proper look round and inspection afterwards, there should not be reason for such lawsuits or for any accusations of bad work. It can only be urged that the test as made by the Supply Company shows absolutely nothing as to how the work has been performed, and a man who goes round with a boy and an ohmmeter and generator has no means of proving anything else than that the insulation resistance of the installation is not low enough to cause serious loss to his employers. Even then cases have been known where the mains have been disconnected at some point for the test, and joined up before the lamps were put in, to show that there was complete continuity.

It cannot be too strongly urged on the public not to listen to touts who call at their houses and ask to be allowed to estimate for the electric lighting, nor to accept the lowest tender invariably because it is the cheapest. It will, without doubt, cost them more in the end than if they accepted the dearest tender. Far better is it to engage the services of a capable consulting engineer with good references, to pay him, say, 5 per cent. on the cost, and to know then that he will take full responsibility for the choice of a good firm, and for the due carrying out of the contract according to his own advice and experience.

SOME ELECTROLYTIC PROCESSES FOR THE MANUFACTURE OF WHITE LEAD.

By SHERARD COWPER-COLES.

Up to the present the old Dutch process of making carbonate of lead has held its own, and it is still the impression that the lead produced by this process is the best as regards its covering capacity. Such was the finding of the Committee appointed by Government to investigate the dangers attending the manufacture of white lead. Carbonate of lead, manufactured by a wet or electrolytic process is found to be more or less crystalline and hydroscopic, and has not the same covering power as white lead manufactured by a dry process.

The amount of white lead produced on the Tyneside is 16 to 17,000 tons a year; a similar amount is produced in France; Italy producing about 3,500 tons a year.

The old Dutch process consists in subjecting desilverised metallic lead (blue lead) which has been melted and cast in wickets (also called crates) which are sometimes in the form of gratings or plates with two holes and a central flat rib to the vapour of acetic and carbonic acid. The wickets are put into stacks or blue beds for corrosion into white lead. This is done as follows:—The floor of the stack, a large cubicle built of bricks, is first covered with a layer of tan, on this are arranged as closely as possible stoneware pots filled with dilute acetic acid, and on the top of these are placed four or five layers of wickets in close contact with each other. The whole is then covered over with boards, forming a second floor upon which fresh layers of tan, pots and wickets, are arranged as above. This is, in its turn, covered in the same way, and so on until the stack is full; as many as 10 or more layers going into one stack. When the stack is full, the ventilating shafts which have been left at each corner of the stack are closed up, and the stack is left to itself for periods varying from 10 to 15 or more weeks. During this time the conversion of the blue lead into white lead takes place. The tan soon begins to heat and evolves carbonic acid, the heat volatalising the acetic acid. An inter-action then takes place between the lead on the one hand, and the carbonic acid, acetic acid, and air on the other, leading through a series of chemical changes not clearly understood, to the ultimate production of an amorphous basic carbonate of lead (white lead); the action goes on until either all the lead is corroded, or all the acetic acid has been volatalised, or no more carbonic acid is produced. During these changes there is always a small proportion of acetate of lead present in the corrosion, some of which is also left in the final product. At the expiration of the time found necessary by experience the stack is opened, and the corroded lead is wetted and carried away in trays to corrugated rolls over which passes a constant stream of water; in front of these rolls the corroded lead is tipped down. In passing between the rollers the wickets are crushed, thereby detaching the white lead from any remaining blue lead. The crushed material next passes into a shallow tank having a perforated bottom, in which it is raked about, separating the blue from the white lead. The blue lead is raked out; the white lead passes with a current of water to grinding mills, where it is ground up and run into a series of tanks; in these the finely divided white lead settles to the bottom, the water is then drawn off, the white lead is removed, put into earthenware or copper pans, and placed in drying ovens. When the white lead is thoroughly dried, which takes from three to five days, the pans are taken from the ovens by hand labour, or mechanical means, and the dry white lead is placed either into casks, or thrown into bins for subsequent conversion into paint.

White lead (carbonate of lead) has two faults, as it is both poisonous to the makers and to the users. The perspiration on the hands has an acid reaction, and tends to dissolve some of the white lead, and this passing into the system, gives rise to lead poisoning. Lead has the property of accumulating in the system, and when a certain amount has got in the system, it is very difficult to eliminate. The other defect alluded to is that of discolouring on exposure to air and sulphurous gases, with which it forms black sulphide of lead.

From the foregoing description it will be seen that the Dutch process is a very slow and tedious one. To overcome these difficulties the following system has been devised. The lead is cast into thin sheets about 20 inches by 15 inches, weighing between 2 and 3 lbs. each. These sheets are then corrugated and packed in crates with plates of coke or carbon which form the negative electrodes. Strips of tin make the connection between the lead or electro-positive plate and the carbon electrode, the object being that when subjected to warm vapours of acetic acid, carbonic acid, and atmospheric air, electrical action is set up between the two, which hastens the corrosion and reduces the time required to convert the plates into carbonate of lead from 10 to 15 weeks (the time required by the old Dutch process) to five weeks. The corroded plates are subjected to a similar process as that already described under the head of the Dutch process.

Another electrolytic process consists in electrolysing a 10 per cent. solution of sodium nitrate in a wooden cell provided with a porous diaphragm, the anode being made of pig lead, and the cathode of copper. In the former compartments the lead dissolves as nitrate, whilst round the cathode caustic soda is produced. The two solutions being drawn off and mixed, the alkaline nitrate is regenerated, and the lead precipitated as hydrate. The hydrate is finally treated with sodium carbonate or bicarbonate to convert it into white lead. The caustic soda formed as a bye-product in the latter operation has only to be recarbonated to be available again.

A somewhat similar process, patented by Mr. Browne, is carried out by placing metallic lead in a suitable vessel in electric connection with the positive pole in the presence of a solution of an acetate or a nitrate of an alkali base. A soluble salt of lead is formed on the anode and a solution of caustic alkali at the cathode. In consequence of the flow of the electrolyte against the cathode these two solutions intermix, with the result that lead hydrate is precipitated, the original alkaline salt being regenerated. The solution containing the lead hydroxide in suspension is then run into a settling tank, from which the clear solution is subsequently drawn off when it is used again as the electrolyte, and the lead hydrate is finally exposed to the air or to an atmosphere of carbonic acid to convert it into hydrated carbonate of lead.

It is to be observed that in reality electrolysis plays but little part in these processes, but the mixture of lead carbonate and hydrate of which white lead consists is purely by chemical means.

Another process patented in America consists in passing an electric current from an anode of metallic lead through an alkaline electrolyte consisting of a solution of a salt of ammonia in combination with any acid which will produce a soluble lead salt (including sulphuric acid) and of a bicarbonate of an alkali to a cathode of lead, carbon or other suitable material, thereby causing a decomposition of the salts in the electrolyte, and a formation of a soluble compound of lead, which is transformed into the hydrated carbonate of lead by the simultaneous generation of free carbonic acid at the anode by the presence of caustic alkali (ammonia) generated at the cathode, passing a current of carbonic acid gas through the electrolyte to regenerate the spent alkaline carbonate until the anode is completely dissolved. Both the acetate and bicarbonate of soda are continuously regenerated, the process consuming only lead, carbonic acid and water.

An English process, which has lately been protected, consists in decomposing acetate of ammonia by electrolysis, lead anodes being used, which are separated by porous diaphragms which are made preferably of stout Willesden paper, which are insulated from the bottom to prevent irregular electrolytic action in the electrolyser. A lead solution is produced, and caustic alkali, when on mixing the two solutions white lead is precipitated. When a series of cells are used, the exit openings at the bottom are closed by elastic bags, which are distended by the fluid within.

In another process patented in Germany, lead anodes 3 mm. in thickness are employed for the electrolysis of a solution containing 300 cc. nitric acid and 2,000 cc. of water. The lead salt formed is precipitated as white lead, and gives off a stream of carbonic acid gas. Any silver contained in the lead is deposited on the cathodes, and can be recovered.

NEW PATENTS.

[*Compiled expressly for this journal by* W. P. Thompson & Co., *Electrical Patent Agents*, 322, *High Holborn, London, W.C., to whom all inquiries should be addressed.*]

1,835. "An improved telegraph cable grip." A. Gray. Dated January 24th.

1,869. "Improvements in insulators." E. Renault. Dated January 24th. (*Complete.*)

1,872. "Curve tracer of electrical measurements." W. Douglas. (E. Ross, United States.) Dated January 24th. (*Complete.*)

1,880. "Improvements in electric pendulum indicators." F. Jones. Dated January 24th.

1,887. "Method of and means for enabling code or cypher printing or signalling to be effected by means of the ordinary keyboards of type-writing machines, telegraphic apparatus, type-composing machines, or the like." J. Ballot. Dated January 24th.

1,912. "Improvements in telephones." J. D. F. Andrews. Dated January 24th.

1,923. "Improvements in dynamo-electric machinery." J. S. Lewis and F. J. Howitt. Dated January 24th.

1,970. "An improved electric switch or contact maker." J. G. Dixon. Dated January 25th.

1,994. "Improvements in safety fuses for electrical conductors." L. A. Ferguson. Dated January 25th. (*Complete.*)

2,007. "Improvements in or relating to transmitting electrical impulses and signals." E. Wilson and C. J. Evans. Dated January 25th.

2,021. "Electrical log recording instrument for the cabin." P. Jensen. (Patentaktiebolaget Svea, Sweden.) Dated January 25th.

2,024. "Improvements in and relating to primary batteries." C. Koenig. Dated January 25th. (*Complete.*)

2,025. "Improvements in rheostats for regulating the current used in electro-plating and other processes." W. P. Thompson. (The Zucker & Levett and Loeb Company, United States.) Dated January 25th.

2,030. "Improvements in primary batteries." E. Giglio. Dated January 25th.

2,039. "An improved relay switch." T. B. Browne and J. M. James. Dated January 26th.

2,040. "An electrical fire call telegraph." W. Blenheim. Dated January 26th.

2,063. "Improvements in switches for electric light service." A. E. Tanner. Dated January 26th.

2,106. "An improvement in, and connected with, electric arc lamps." J. O. Girdlestone and C. F. G. Thorkelin. Dated January 26th.

2,167. "Improvements in, and connected with, electric generators for cycles and other vehicles." J. Moores and H. O. Farrell. Dated January 27th.

2,171. "An electric bell piano." S. J. Godwin. Dated January 27th.

2,172. "Improvements in attachments to electric incandescence lamps." C. H. Stearn. Dated January 27th.

2,215. "Improvements in, and connected with, the generating of electricity through the motion of the rolling stock and the like." M. Clark and J. B. de Atzugaray. Dated January 27th.

2,266. "Improvements relating to electric plating." J. Matthews and T. Vann. Dated January 28th.

2,284. "A new application of the electric incandescent lamp." J. R. Payne. Dated January 28th.

2,292. "Improved insulator for telegraph wires and the like." H. Peters. Dated January 28th.

2,299. "Improvements in joints between the glass globes of electric arc lamps and the supports by which they are carried." P. H. Guerin. Dated January 28th.

2,308. "Improvements in electrical advertising apparatus." P. C. Pope and J. F. Simpson. Dated January 28th.

2,375. "A teletypograph for transmitting, receiving, and recording messages through a telegraph wire electrically." J. Campbell. Dated January 29th.

2,382. "Improvements in, or relating to, electric telegraphy." P. Picard. Dated January 29th.

2,389. "Improvements in secondary batteries." J. V. Sherrin. Dated January 29th.

2,415. "Improvements in methods or processes for electro-thermally treating materials, and particularly with reference to the manufacture of calcium carbide and apparatus therefor." H. Maxim and W. H. Graham. Dated January 29th.

2,417. "Automatic electric circuit breakers." M. Bouchet. (Date applied for under Patents, &c., Act, 1883, Sec. 103, July 2nd, 1897, being date of application in France.) Dated January 29th.

2,420. "Improved means for controlling the working of lifts, motors and other appliances operated by electric energy." W. A. Kerr. Dated January 29th.

2,423. "Improvements in the manufacture of filaments for incandescent electric lamps." R. Mullard. Dated January 29th.

2,426. "An improved method of and means for facilitating the starting of single or polyphase alternating current motors and the like apparatus." M. Deri. Dated January 29th. (*Complete.*)

2,427. "Improvements in variable electric resistances or rheostats." R. Waygood & Co., Ltd., and P. I. Unwin. Dated January 29th.

2,428. "An improved electrical transformer for currents of high potential and variable frequency." A. Wydts and O. M. Rochefort. Dated January 29th.

THE

ELECTRICAL REVIEW.

VOL. XLII. FEBRUARY 18, 1898. No. 1,056.

CONTENTS:

THE ELECTRICAL REVIEW.

Published every FRIDAY, Price 4d.

The Oldest Weekly Electrical Paper. Established 1872.

TO BE OBTAINED BY ORDER FROM ANY NEWSAGENT IN TOWN OR COUNTRY.

OFFICE:—4 LUDGATE HILL, LONDON.

Telegraphic Address: "AGEEKAY, LONDON." Code A B C.

Telephone No. 963 Holborn.

ALL Letters should be addressed to the Proprietors, H. Alabaster, Gatehouse & Co.

ADVERTISEMENT RATES ON APPLICATION.

The "Electrical Review" is the recognised medium of the Electrical Trades.

SUBSCRIPTION RATES.—In *Great Britain*, Post Free per Year, 19s. 6d. To *all other countries*, per Year, £1 4s.

BINDING.—Subscribers' numbers bound, including case, for 4s. each volume.

CASES.—Cloth Cases for Binding can be had, price 2s. 6d. each.

READING CASES, to hold from One to Twenty-six Numbers until the Volume is complete for Binding, can now be had from the Publishers, Price 6s. or Free by Post (in Great Britain), 6s. 6d.

FOREIGN AGENTS.—*New York:* D. VAN NOSTRAND, 23, Murray Street. *Paris:* VEUVE J. BOYVEAU, 22, Rue de la Banque. *Berlin:* ASHER & Co., 5, Unter den Linden.

Cheques and Postal Orders (on Chief Office, London) to be made payable to Mr. H. ALABASTER, 4 Ludgate Hill E.C.

ELECTRICITY SUPPLY CONSIDERATIONS.

ANOTHER year has come and gone, and the counting of units generated, units sold, and units not accounted for, is no doubt proceeding apace with the enthusiasm one finds at the counting of the votes at election times. The time is fast approaching, if it has not actually arrived, when we shall be in possession of the returns of the many electricity works spread about the country. The older stations have reached a standard in low cost of production, as concerns coal, oil, &c., which it will be difficult, in many cases, to improve upon. In the more recent stations we expect a general improvement in these items, and we confidently expect to find a marked lowering in the case of the "two and three-year-olds."

That the supplying of electricity from a central station is a financial success is undisputed, and although some of the balances of the youngest concerns last year were on the wrong side, we shall no doubt find the majority of these, if not all, transferred to their proper side, where permanency is assured.

It is not our intention in this article to deal with the financial side of the question, but to give voice to some points which have occurred to us from time to time, and which, at this period, may not be uninteresting.

The first question which suggests itself is: What is the proper amount to put aside for depreciation? How long will it be before our engines, boilers, machines, &c., wear out? The answer may be that although the percentage put aside at present is small, it will be increased year by year as the machinery gets older, until ultimately things will be right. This may be approximately correct as regards the buildings, switch gear, and running plant, but who can tell us the life of the mains? A very large proportion of the capital expenditure is spent in mains. These are being continually added to; a short extension here and another there adds unconsciously as it were, until the aggregate amount at the year's end is enormous. We may select what appears to us the best main, and exercise great care in the handling and laying of the same, and by repeated tests made at regular intervals keep as watchful an eye upon this part of the installation as it is possible to do, and yet we cannot even guess how long it will be before they have to be taken up and replaced by others.

This is a most serious question. Because the mains are out of sight, they should not be out of mind.

Bare copper strips supported on porcelain insulators laid in stoneware conduits seem to have the best prospect of longevity. It is not always practicable to adopt this system, owing to the shallowness between the pavement and the cellar tops, also the presence of gas and water pipes which cross the pavements at varying depths render a capacious straight conduit an impossibility. This system has never been carried out in its entirety for these reasons, and also in consequence of the difficulties met with in crossing the roadways, when India-rubber cables drawn into cast-iron pipes are most generally resorted to.

Cheapness in cost and laying seems to be the principal factor, at present, which governs the selection of a system of mains. Will the cable which costs so much per yard less than another, last as long? We know that steel armouring will not last for ever, neither will lead sheathing, nor the dielectric whatever it may be. The soil in which the cable is laid will materially affect its life. Instances of this kind are common, and heavy expenditure, quite unexpected, has been the result. Every precaution is taken by cable makers to supply mains which will last as long as possible, but can they guarantee even an approximate life, taking into consideration all the local circumstances? If not, why not?

We constantly have our moving machinery under observance, and we rectify before it can develop into a serious complaint any little irregularity that may be found. As we said before, we test our mains as often as practicable, for insulation leakage, but not for actual depreciation in the steel armouring, lead sheathing, or dielectric. We test our engines for efficiency with an engine indicator, but does it tell us when to put new brasses in the main bearings? We test our dynamos with suitable instruments for insulation, but do these instruments tell us when a new commutator is required?

It would be just as absurd to expect such information from these sources, as it is to assume that our mains are as good as when laid, because the insulation is high and the leakage low.

It would be well if directors of companies would carefully weigh these questions before declaring dividends, and allowing the depreciation to remain at "nil." Now is the time to prepare, and not wait till the calamity comes, and then be unprepared. Municipal authorities are not so likely to err in this respect, owing to the conditions under which their respective loans were granted. It would be well, however, for them to ask themselves this question—Are we allowing enough for depreciation on our mains? May the day be far distant when the mains of the country have to be replaced by others; but if no other item than the natural decay of all material had to be considered, it would only be a matter of time, and let us hope to see the word "nil" under the heading of depreciation removed from all the balance-sheets of all the electrical supply companies this year; if not all, at least those who cannot lay claim to being infants.

SUBSIDISED CABLE COMPANIES.

In the half-yearly report which the directors of the Cuba Submarine Telegraph Company have just issued to the shareholders, we notice a significant fact, indicating the policy of the Treasury and Colonial Office Departments of the Government in dealing with telegraph companies. The point to which we wish to draw attention is comprised in one of the paragraphs of the report, where it is said: "In consequence of the establishment of the new line between Bermuda and Jamaica, subsidised by the British Government on the basis of a charge of 3s. per word between the United Kingdom and Jamaica, the Cuba Company have been compelled to accept reduced rates, which will result in a considerable loss of income."

We have here a company—one of the pioneers—which doubtless had many a severe struggle to maintain, unaided, its existence in the early days, threatened, in its prosperity, by a competing line.

To ordinary competition every company is liable, unless they hold exclusive rights, and shareholders take their risks; but when, as it appears in this case, the Government comes forward and subsidises the new competitor, without giving an equal subsidy to the existing line, one would think that some injustice is being done. No one can contend that the new line is not an admirable one; it connects Halifax with Bermuda, Bermuda with Turk's Island, and Turk's Island with Jamaica—all British possessions. It may have been highly desirable, from an Imperial point of view, that such a line should be established, even if the private interests of certain British subjects should be damaged, on account of the necessity of it for the commonweal, and in that case we agree that these minor interests should be overridden. This has, apparently, been the view taken by our governors.

We sympathise with the shareholders of the Cuba Company, as, besides fighting a subsidised competitor, they will lose the receipts from the official traffic, which will surely pass by the all-British line, and there is also a lowering of rate to face which must, at least for a year or two, seriously affect their company's revenue.

May we not suggest that a partial remedy for their condition may be found in the Cuba Company approaching the British Government, not with the view of asking for complete compensation for damage sustained by the laying of the new Imperial cable, but with the object of obtaining from the Imperial Parliament monetary assistance equivalent to that granted to the new competitor. In this the company may succeed, as the British Government, representing the general community, may think it proper to grant some compensation for the damage this Government has caused to the company while acting in the public interest. The Cuba Company's case would appear all the stronger, in that the new line affords only a single means of communication, while the Cuba Company's route is duplicated throughout, and would appear to be necessary for the security of communication between the Home Government and the West Indian Colonies.

As precedents in electrical matters, where the Government has dealt with compensations, we have the purchase of the land telegraphs by the State, the arrangements with the Submarine Telegraph Company, and with the National Telephone Company. There are doubtless many other instances of compensations in the experience of the War Office, Admiralty, Colonial Office and Treasury, which resemble the case of the Cuba Submarine Company.

Tesla's Latest Advances in Vacuum Tube Lighting.

In a letter to the *Electrical Review*, N.Y., Tesla describes the results of some recent experiments he has made in vacuum tube lamps, and in their application to photography and other purposes. Along with the letter are published copies of photographs taken with Tesla's new vacuum. One is a portrait taken by the light of a single vacuum lamp at a distance of 5 feet with an exposure of five seconds. Another is a page of letterpress taken by a single vacuum tube at a distance of 4 feet with an exposure of two seconds. The photographs are not equal to sunlight photographs, but resemble more those taken with a single magnesium flash light, the shadows being very harsh, but the amount of detail is considerable. It is difficult to say from Tesla's letter in what his improvements exactly consist. He appears to have reduced the size of the vacuum tube, and thereby, as he says, considerably reduced the dissipation of energy from its surface. The illuminating power of the lamp with which the photographs were taken he estimates at 1,000 candles. The great superiority in efficiency of his system over earlier attempts at vacuum tube lighting he considers is principally due to the use of his improved apparatus for "producing economically harmonical electrical vibrations of extreme rapidity," referring, no doubt, to his oscillator recently described in the Electrical Review. Tesla promises soon to give further details of his system. The well known originality of nearly all Tesla's investigations leads us to look forward to the publication of the full description of his new system.

DEATH BY ELECTRICITY.

By W. S. HEDLEY, M.D.

It is not always so easy as might be supposed to kill an animal by electricity. The experiments of Brown-Séquard and D'Arsonval long ago * showed this, and many physiologists have since confirmed it. Kratter found that one short application of an alternating current at 1,500 volts sometimes did not kill either rabbits or guinea-pigs. Yet much lower voltages have often proved fatal to man. Indeed, it seems not improbable, as the present writer has elsewhere † stated, that all commercial forms of electric lighting currents, varying as they do from 80 volts upwards, may be dangerous to human life under certain conditions. It is, of course, true to say, that, other things being equal, risk increases in direct proportion to the electromotive force; but absolute equality of "other conditions" can never be secured. The duration of the application, the nature of the contact, its superficial area and position, the condition of the skin, the periodicity of the current, the species of animal, its weight, age and perhaps even its state of health, are all factors in the result. That duration of contact has a most important bearing on the question, is nothing more than might be expected, for reasons both physical and physiological, and all experiment proves it. It has been shown ‡ that currents, easily borne by an animal when momentarily applied, were fatal when the application was prolonged to 5—10 seconds. On the other hand, short but repeated applications of strong currents were almost invariably fatal. When other conditions are the same, the larger the area of contact, the greater the intensity of the current; but the less its density, and the latter can never be left out of consideration in dealing with physiological effects. The condition of the skin, with reference to moisture, or any breach in its continuity, is also a point of the first importance, inasmuch as the epidermis is the great insulator of the body. But, at the same time, it is to be remembered that the degree of skin injury is not always proportional to the gravity of the accident. Frequency of alternation must also be considered. It may be that fatal effects are in inverse ratio to the periodicity, although not perhaps according to a strictly "straight line law." Animals present differences in their resistance to the effects of electric currents according to their species, and even according to their individual peculiarities. Every animal seems in this respect to be a law only unto itself. It was found in the experiments already alluded to that rabbits often survived currents which proved fatal to dogs ten times bigger. In the original electrocution experiments in America, experiments were made upon a horse, three calves, and a number of dogs. The mean fatal current thus obtained was brought to bear upon the man to be executed, and the result proved a painful *fiasco*. Yet many experiences since then, some of them within recent months, have proved that a low as well as a high electromotive force may kill a man.

It is very generally admitted that in the case of animals killed by strong currents, there is a tolerable uniformity in the *post-mortem* appearances: (1) the latter in many respects resemble those seen after death by asphyxia (apnœa); that is to say, the left side of the heart is comparatively empty, whilst its right side and the larger veins near it are distended and filled with dark fluid blood. The absence of hæmoglobin from the blood is also a fact common to death by electricity and to death by apnœa. (2) The nervous system does not seem to present any very characteristic appearances, at least there is no "gross lesion" which can be said to be constantly present; but slight hæmorrhages in the walls of the fourth ventricle and in the meningeal coverings are not rare. Yet there may be many finer molecular changes in the nervous tissues of which present methods of investigation are not able to make us cognizant. (3) The points of penetration of the current are always evidenced by burns of various degrees. Less constantly the place of exit is similarly marked. These burns of entrance have considerable diagnostic value in cases when the cause of death may be in doubt. They may vary in severity from simple redness to complete destruction of the whole thickness of the skin; but, as already said, their severity has no close relationship with the gravity of the accident.

When a strong current is brought to bear upon a living animal, there is immediately a strong tetanic contraction of the entire striated muscular system; and on the circuit being broken there is often a deep inspiration, perhaps followed by an "expiratory cry." It is often this cry which first calls attention to the accident. In cases which are not fatal there is often loss of consciousness, which may be regarded as the clinical manifestation of the severe shock, or rather shaking, to which the whole central nervous system has been subjected. This is very different from what is surgically known as "shock." In the latter, the longer the condition of shock lasts the greater the danger. In electric accidents, danger of death *diminishes*, the longer the duration of loss of consciousness. It may be said that, if not immediately killed, the person usually recovers. This loss of consciousness soon disappears, perhaps, even, in a few minutes, but for days or weeks there may remain "head symptoms," such as vertigo and severe headache, or there may be palpitations or other such consequences. Neither sensory nor motor paralysis appear to be common.

Death, as the result of electricity, must occur in one of two ways—(1) by mechanical lesions of vital structures, or (2) by arrest of organic functions essential to life; that is to say, by arrest of respiration, heart action, or nutritive exchanges. It is in persons killed by lightning that the first-named mechanical or "disruptive" effects are usually seen. Industrial currents kill in the second way. But even here the difference is quantitative rather than qualitative. Most of the foregoing points have been put in evidence by Kratter and others, and, as already said, are generally accepted. The first class of cases need not be considered. It is self-evident that mechanical disintegration of vital parts must cause death. But, approaching the second class of cases, where death occurs by arrest of organic functions essential to life, the question broadens out, and it becomes necessary to inquire which of such functions is struck first. Where does death begin? What is the "mechanism" of death by electricity? At this point physiologists are no longer in accord.

Is it as D'Arsonval considers, that, acting on nervous centres, the electric current produces a variety of effects known as "inhibitory," viz., suspension of respiration, arrest of heart action, &c., and that it is the first of these that is primarily affected, inasmuch as cardiac action persists after the arrest of respiration. According to this view, there occurs, in fact, "a central paralysis of respiration, constituting a special form of asphyxia," * due to exhaustion of the medulla and functional death of the ganglion cells. If this be correct, artificial respiration affords a hopeful means of restoring animation. This condition of suspended respiration must not be mistaken for death, and a *post-mortem* examination at once proceeded with. "Nécropsiés vivants" is the sensational term which, it may be remembered, was used in connection with the autopsy of the first electrocuted criminals in America.

Dr. Tatum, of New York, experimenting in 1890, came to the conclusion that strong currents kill by acting chiefly or entirely on the actual substance of the heart itself.

In 1895, Dr. L. Jones, having witnessed some experiments undertaken by Mr. Bokenham with reference to the amount of current required to kill anæsthetised cats, considered, from an inspection of the respiration and blood pressure tracings, that death began at the heart, and that the action of the current is "upon the heart muscle rather than upon any of its nervous mechanisms." In the *British Medical Journal* of January 15th, 1898, there appears a paper by Drs. Oliver and Bolam on the same subject, arriving at the same conclusion, and by the same methods, but not giving such details of amperage and voltage as would enable the experiments to be repeated by others.

Against these latter views it has been urged that were the heart's action suddenly arrested by the electric shock, there would not be the great disproportion in the amount of blood on the two sides of the heart that is present in death by electric shock. After sudden arrest of the heart's action, the amount of blood on the two sides of the heart is nearly equal.

* 1884.
† Electrical Review, January 28th, 1898.
‡ Kratter.

* Kratter.

Further, the heart theory rests chiefly on blood pressure tracings, and it is to be remembered that blood pressure is the result of other factors, in addition to the action of the heart.

This leads to another hypothesis. Dr. Bleile, of the Ohio State University, suggests, as the result of carefully conducted physiological experiments, that death by electric shock is entirely due to the fact that the current produces a contraction of the arteries through an influence on the nervous system; that is to say, through an effect on those nervous centres which control the diameter of the arteries, and that a constriction of the arteries so produced throws in such an impediment to the flow of blood as the heart is unable to overcome. This last-named hypothesis no doubt contains an important truth, recognising, as it does, the fact of peripheral obstruction as influencing blood pressure.

It is, however, contended* that the fatal obstruction is not in the systemic arterioles, but is owing to a constriction of the pulmonary arterioles, the latter being excited to contract by the entirely deoxygenised blood. Such a theory obviously falls into line with the *post-mortem* conditions, which, as has been seen, resemble those seen in apnœa.

It would, therefore, appear, not, perhaps, that each of these hypotheses are at hopeless variance, but that death from electricity may be accomplished by various physiological mechanisms. First, and perhaps oftenest, it may be by sudden arrest of respiration; at another time it may be brought about by sudden and primary stoppage of heart action; in either case, the result being not improbably due to physiological death of the centres of respiration or circulation from chemical and morphological changes therein, which present methods of observation do not enable us to recognise. Further, it is certain that these two centres act in unison, and it need not be surprising that the incidence of the damage done by the current may not always be distributed in the same way. But in accepting the foregoing, it is not to be overlooked that the view that fatal results from electric currents are due to damage inflicted within the actual structure of the heart itself is very influentially held, it has never been disproved, and may ultimately turn out to be a cause, if not *the* cause, of death from electricity. Thirdly, mechanical or disruptive lesions, such as tearing of blood-vessels and contusions of of the surface of the brain, are not limited exclusively to accidents by lightning, but have also been observed in a modified form in cases of death from industrial currents.

A short code of rules for guidance in such accidents has been ably formulated by the ELECTRICAL REVIEW, and the present writer has dealt with the subject of "first aid in electric accidents" in an article under that name in the *Lancet*, August, 1894. It is sufficient to say that, notwithstanding the experiments of physiologists, and a growing experience of such cases, all that medical treatment can do is still to be summed up in the original formula of D'Arsonval, "Un foudroyé doit être traité comme un noyé;" in other words, by artificial respiration commenced early and continued long. But there is one further point with reference to this to which brief allusion may be made. It is known to physiologists that animals to whom nitrite of amyl has been administered are more difficult to kill by electric currents than are animals not under the influence of that drug. It acts by paralysing the walls of the small blood vessels, and so doing away with both arterial constriction and pulmonary obstruction. Now, without advocating that capsules of amyl nitrite should form part of the equipment of every "first-aider," it may be suggested that the use of this drug in cases such as drowning and electric shock would in safe hands prove a valuable adjunct to artificial respiration.

* *Lancet*, October, 1895.

THE ELECTRIC LIGHTING OF WASHINGTON.

THE new plant of the United States Electric Lighting Company at Washington, D.C., is very fully described in detail in the *Electrical Review* of New York by Mr. Geo. H. Draper. On reading this excellent description of the new station supplanting the old, it is forcibly brought before us the rapid progress which electrical generation and distribution is making, when we find a comparatively recent works being replaced by a more modern plant and buildings.

It follows that the demand for electricity must also be increasing in proportion to warrant this enormous expense. A section of land has been secured which will allow of plant installed to supply ultimately a very large proportion of the lighting of the city.

The present plant can with ease be quadrupled when necessary, affording an output of 500,000 16-C.P. incandescent lamps or its equivalent in other forms of electrical application. To compare this capacity with that of our largest stations, we must reduce the figures to a common denomination. We count our capacity in 8-C.P. lamps, therefore the Washington station will have a capacity of no less than 1,000,000 of these lamps.

If the American proportion of plant capacity to lamps installed is the same as ours, then nearly 2,000,000 8-candle-power incandescent lamps or their equivalent can be connected to their supply mains before a further extension of their works becomes necessary.

There are two companies supplying electricity in the city, and this no doubt engenders healthy competition. Whether each company vies with the other to give a little extra voltage, and consequently a better light, we do not know; but this we do know, that the people of Washington, D.C., are reported to be complaining of the quality and price of the illuminating gas supplied to them. The street lighting of the national capital is also claimed to be inferior. Added to these facts the assertion that not 2 per cent. of the residences in Washington are lighted by electricity, we begin to realise why the United States Electric Lighting Company is making such elaborate preparations for a much more extensive supply.

Unfortunately, there are restrictions surrounding the extension of the subway system in Washington so severe as to be in some cases almost prohibitory. This is a serious drawback, for no matter how cheaply current may be generated, it cannot be sold to consumers at a low figure unless an economical means of distribution is available. Notwithstanding the retarding influence of these restrictions, the new plant referred to above, and which will soon be in operation, will enable current to be generated at reasonable and distributed at profitable rates.

Barriers of this kind cannot exist for ever, and with the opportunity of building or using sufficient subways for its purpose, the company should be able, in the near future, to remove any complaints as to service and prices.

In England we are striving to eliminate belt driving, for economic reasons, and it is therefore a little surprising to find that belt driving enters somewhat largely into the composition of the new plant under consideration.

The local circumstances may differ, yet where the size of the units are large, one generator, one engine, seems to us to be the rule.

In Washington, however, we find a combination which, on the face of it, seems economical, to say the least of it, although there are objections, which we will immediately point out.

Two large horizontal compound condensing engines in the basement operate a long length of shafting also in the basement, which in turn drives eight Brush 125-light multicircuit arc dynamos by means of belting passing through the floor. Each of these large engines operates a direct-coupled low tension generator, either of which is capable of carrying the entire load. The arc machines may be thrown in or out of service as required by means of the shafting, by steel clutches, 5 feet in diameter. Although this arrangement provides for an economical operation of both the three-wire low tension and the arc light systems from one engine during the period of light load, we, in England, have learned our lesson, and profited thereby. Our opinion of this arrangement is that it savours too much of putting one's eggs all in one basket.

A slight accident to either dynamo, engine, or shafting would probably result in an entire dislocation of supply, and after all, the first consideration of the central station engineer should be continuity and regularity of supply, and economy of production and distribution afterwards.

In addition to the eight Brush arc lighting machines before mentioned, are two General Electric Company's alternators, one A-70 1,040 volts, 125 cycle, one A-30 1,040 volt, 125 cycle, also driven by belting off the common shafting. A third alternator is to be run by a motor.

The interruption in supply is somewhat provided for by the employment of a large relay of storage batteries. The function of this battery is to help over the "peak" at time of heavy load. The battery comprises 150 cells, and has a capacity of 2,000 amperes on a side for three hours, and is so arranged that it can be connected with either the main bus bars or all feeders, and thus can always be used to best advantage. This battery is charged at times of lightest load in the small hours of the morning, and from 9 a.m. till 3 p.m.

The boilers are the well-known Babcock & Wilcox type, so largely used in our own stations, working at a pressure of 160 lbs. There is also a very large economiser, containing the feedwater, and affording upwards of 10,000 square feet of heating surface, thus heating the water from its ordinary temperature to the highest possible degree.

The switch-gear, one of the most important apparatus in a station, has received special attention. It extends the whole width of the engine room wall, operating the entire service of the company, comprising the low tension three-wire systems arc and alternating systems and the accumulators.

The whole of the apparatus is mounted on panels made of blue Rutland marble, highly finished, the instruments and appliances being the latest and finest instruments known to the electrical art.

We generally associate with America overhead distribution, but in Washington, at least, the underground system of mains is almost entirely used, very few overhead mains existing.

As previously mentioned, certain restrictions are in existence which greatly hinder the progress of electricity supply. No additional conduits can be laid, except by direct act of Congress; this does not, however, prohibit the repairing of the existing conduits. Owing to lack of experience, some of the original conduits, which were among the first to be laid in the country, are now in poor condition; moreover, the duct capacity is too small for the increased business. Owing to these defects, the company is at present engaged in rebuilding and modernising over 50 miles of conduit and cable system. Cost has been a second consideration in regard to efficiency. The conduits are simple in construction, and should prove efficient and durable.

What is known as the Lynch-Lake four-way glazed terra-cotta pipe is used, and also the camp glazed terra-cotta single duct, each having round holes 3 inches in diameter. This is laid at a depth of 30 inches from the top of the top duct to the surface of the street, on a base of 4 inches of Portland cement concrete, with 1 inch of the same material laid between each layer of conduit, and 4 inches of concrete is placed on the top and both sides. The joints are butt joints, and over each seam a strip of cotton is laid, which is then plastered over with Portland cement mortar before any concrete is put upon it. A mandril is used to ensure a perfectly clean joint before another length is laid. These joints are clean and perfectly water-tight. Large manholes, 5 feet square by 6 feet deep, fitted with cast-iron covers 5 feet × 5 feet, are built up in two or more pieces. All manholes are drained either to the nearest sewer or to the next manhole, and iron back water valves are used.

Throughout the whole plant, simplicity and durability of arrangement and design seems to have been aimed at, together with the best types of mechanical and electrical service to be had, and the prospects of the company now should be very bright, and we hope its progress will not long be hampered by irritating restrictions which seem to be unnecessary.

A DEPARTMENT OF ELECTRICITY FOR CHICAGO.

Judging from appearances and results, America has not in the past been noted for its restrictive legislation or protective supervision where the generation and distribution of electrical energy has been concerned, as the crowds of bare overhead conductors carrying high-tension currents, and the numerous fatal accidents thereby occasioned from time to time, bear witness. Chicago, however, appears to be waking up in this direction, and, according to the *Western Electrician*, the City Council propose creating a Municipal "Department of Electricity," with officers and staff consisting of: "A city electrician, an assistant city electrician, a superintendent of construction, a chief clerk, two book-keepers, two stenographers, one chief inspector, and nine assistant inspectors, and such other assistants and employés as the City Council may by ordinance establish." The creation of the department, duties and salaries of officials, regulations, fees, and penalties, are to be included in paragraphs 589 to 598, inclusive of Chapter XXV. of the "Revised Code of Chicago, 1897."

Paragraph 589 embodies the name of the proposed department and enumerates the staff.

Paragraph 590 creates the office of city electrician, states that he shall be a practical and skilled electrician, shall not engage in any other business, shall be appointed by the Mayor, and shall hold his office for two years. So far, good.

Paragraph 591 provides that the said city electrician, before taking office, shall execute a bond to the City of Chicago, with approved sureties (number not mentioned) in the sum of $20,000! "conditioned for the faithful performance of the duties of his office." As shown in the next paragraph, the salary is to be $4,000, the bond being equal to five years' salary! Evidently the Council anticipate a heavy revenue to the department from fees and penalties, and it is not a very cheerful prospect for the producers and consumers of electrical energy. We presume the bond is intended to cover possible defalcations as negligence or other similar offences could surely be adequately met by requiring his resignation.

Paragraph 592 deals with powers, subordinate officers' bonds, and salary. The duties of city electrician include "the management and control of the fire alarm, telegraph, and police telephone system, of all municipal electric lighting, of the inspection of all electrical wiring within the City limits, both inside of buildings and above, beneath, and upon the surface of the streets, and of all electrical matters in which the city is interested." Salary, as stated above, $4,000 per annum.

Paragraph 593.—Assistant city electrician, qualifications, duty, salary. The assistant to be capable of taking the duties of his chief in his absence. Salary, $3,250 per annum.

Paragraph 594.—Superintendent of construction, duty, &c. To put in new circuits and instal all new work of the city, under the chief. Salary, $1,800 per annum.

Paragraph 595.—Other officers, powers, duties, salaries. All other officers with their powers, duties, and salaries engaged and fixed by the city electrician.

Paragraph 596 provides that "no electric current shall be used for illumination, decoration power or heating, except as hereinafter provided."

Paragraph 597 requires that "all persons, firms, or corporations," desiring to use electric currents for purposes set out in paragraph 596, shall, before commencing any electrical construction whatever, "either installing new electrical apparatus, *or repairing apparatus already in use*" (italics are ours), "file an application for a permit therefore in the office of the city electrician," describing in detail the work to be done, and "upon receipt of which application, if found proper, such permit shall be given."

While reasonable supervision of wiring and other work on consumers' premises is proper and necessary, both in the interests of consumer and undertaker, we cannot help thinking that this is carrying supervision to the point of absurdity, if not prohibition. As the paragraph reads, and in the absence of further explanation, the unfortunate consumer has to be deprived of his light, power, or heat for hours, or it may be days, if the city electrician chooses to be obstinate, because, forsooth, a switch goes wrong, or some trivial matter, which may be classed as "repairs," requires doing. How, in the name of common sense, can repairs to "apparatus already in use" concern the City Council?

But there is more to follow:—

Paragraph 598 empowers the city electrician, and it becomes his duty, to inspect installations both before and after its completion, and may remove laths, plaster, boards and partitions, in order to inspect current carrying conductors; should he find that the work has been done in accordance with the rules and requirements of the fire department, he shall issue a certificate—after receiving a fee—and the use of the current is unlawful until such fee is paid and certificate given. He may, however, issue a temporary permit before completion.

Paragraph 598A.—"A preliminary certificate may be issued by the city electrician in the case of completed installation, but upon which no current will be used in the immediate future." This certificate is to state that, at the time of inspection, the work was in order, and the fee shall be one-half the regular rates; before current is put on, another inspection is required, and, if still in order, the remainder of the fee is to be paid and final certificate given. The object of the preliminary certificate is not apparent, unless it is to fill up the time of the officials, as no current can be laid on until a further inspection and certificate is granted; and it is no consolation to the unfortunate householder, who wants the current, to know that three months ago his wiring was in perfect order, when a "dead earth," or other defect, prevents his being connected.

Paragraph 598B.—"The city electrician is hereby empowered to inspect or re-inspect all overhead, underground, and interior wires and apparatus conducting electric current for light, heat, or power," and if found unsafe to either life or property he can order them to be put right within 48 hours; failing which, a penalty of $10 may be imposed for each and every day they continue in an unsafe condition.

Paragraph 596C provides that all poles and manhole covers, now in existence or hereafter fixed, shall be stamped with the owner's name, and all services shall be labelled with the owner's name, and such a full description of the conductors as shall meet with the approval of the said city electrician.

Paragraph 598D prescribes the fees for permits and certificates as follows:

For each arc light	$1.00
For each 16-C.P. incandescent or equivalent ...	.10
For each E H.P. of 746 watts used for power or other purpose than above	1.00
Minimum charge for inspection	1.00
Inspection of temporary installations, show windows, exhibitions, &c., at the rate, per hour, of	.50
For re-inspections, half the above fees.	

Paragraph 598E requires the city electrician to issue a yearly report, giving a full and accurate account of all inspections made and moneys received!

Paragraph 598F.—No alterations to be made to any installation without the previous sanction of the city electrician.

Paragraph 598G.—Any violation of these provisions entails a penalty of not less than $50 nor more than $100, and a further penalty of $10 per day as long as it continues. The city electrician may also order and compel the cutting off of the supply until the provisions are fully complied with.

Against reasonable supervision on the part of the local authority of all work affecting the public safety, particularly that executed and maintained by private enterprise, we have nothing to say, indeed, it is necessary and right, but when it comes to the infliction of corporation inspectors into private premises we draw the line.

Imagine what this means. A private citizen requires or desires the current for lighting his dwelling house. He is generally perfectly ignorant of all rules and regulations, and relies upon his wiring contractor (poor man) to do all that is needful. Such contractor, if unscrupulous, and we presume that even in America there may be some, does everything he can to evade inspection. The city electrician gets to know, and a $50 fine is the result. Suppose, however, that the contractor gives the required notice, and the city electrician cannot immediately attend, or does not deem it necessary, the work proceeds. The Fire Insurance Company require their rules to be obeyed; the Supply Company also has rules and inspectors. The fire department of the city has rules, and lastly comes the city electrician, whose ideas of good work may far transcend those of all the others. At his orders down comes lath and plaster, partitions, or other obstructions, to enable him to inspect, and then it may be condemned, and have to be re-done; but if passed, a fee of 10 cents per lamp is demanded. Again, the city electrician's standard of excellence may be much lower than that of the supply company's engineer, and after the City Council's fee is paid, and permit given, the supply may be refused. We should think that such espionage would become intolerable, and that if would-be consumers knew the facts, they would leave electric lighting severely alone, and use candles.

Municipal supervision of this kind would never find favour in England, and we should think it would cause trouble in America.

We should be glad to welcome in England any reasonable measures which would effectually drive bad wiring out of the field; but we think it may be safely left to the fire offices and the supply undertakers' engineers, provided they are properly backed up by legislation—whether compulsory or permissive only.

The imposition of fees for inspection of private premises on the part of the municipality, when such inspection is rendered by it compulsory, is bad in principle. If the wiring is bad the consumer alone suffers, unless it is so utterly bad that all precautions have been neglected—such as an entire absence of cut-outs and other defects almost inconceivable in the 19th century—when, in case of fire, it may of course spread to other premises.

In any case, if the present condition of house wiring in Chicago has necessitated inspection, fees and penalties as above set forth, it must be pretty bad, and we may congratulate ourselves that it is at any rate not necessary in England.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

At the meeting of the Institution of Electrical Engineers held at the Institution of Civil Engineers, on Wednesday, the 9th inst., the discussion on Major-General Webber's paper, "Notes on the Electro-Chemical Treatment of Ores Containing the Precious Metals" was resumed, and on completion of the discussion Mr. Sherard Cowper-Coles read a paper describing "An Electrolytic Process for the Manufacture of Parabolic Reflectors."

Mr. Sulman had evidently not exhausted his offensive ammunition in the speech he made at the previous meeting, and the first contribution to the discussion on Major Webber's paper—after the routine business had been got through—was a categorical list of questions submitted in writing by Mr. Sulman, wherein he returned to the attack on the Pelatan-Clerici process with renewed ardour. In a series of 12 elaborate questions he sought to demolish M. Pelatan completely, and although his rival made out a very good case in his replies, we cannot but thank Mr. Sulman as being the agent by whom a very valuable appendix to the paper was obtained.

The more important items of information were, that the capital cost per tank of a plant for the treatment of 100 tons of ore per 24-hour cycle is: Treatment tank, 9 feet diameter, capable of dealing with 5 tons per day, costs £60; 20 such tanks are required, and the whole plant costs, say, £5,000, exclusive of crushing apparatus. Respecting a statement in the second question that with a sludge containing only 60 per cent. of water, one horse-power is usually found necessary for agitation, M. Pelatan replied that the power depended upon the nature and density of the ore; as little as one-fifth of a horse-power had been found sufficient, while the figure in the paper was ample. If one horse-power were required it probably included that necessary to revolve the containing vat or barrel.

Coming to the cost of treatment per ton with a plant capable of dealing with 100 tons per 24 hours, M. Pelatan gave the following figures in reply to Mr. Sulman:—

	s.	d.		s.	d.
Chemicals	2	6	to	4	0
Power	1	0	„	1	6
Labour	0	6	„	1	0
	4	0	„	6	6

600 lbs. of mercury were used in each tank, the loss being due to mechanical causes and amounting as a maximum to 2 ozs. per ton of ore. No attempt is made to recover the

cyanide. It was claimed for the process that it was exceptionally suitable for ores which yielded very poor or no results by ordinary methods, and as it can deal with ores crushed to pass through a very fine mesh, it evidently can deal with slimes.

The catechism ended, Mr. McMillan then read a communication from Mr. D. A. Louis, in which this gentleman—well known to many as a chemical expert who has paid special attention to metallurgical questions—expressed his feeling that the paper was admirably conceived, commented upon the general data offered, stated he thought the mill illustrated prodigious, and made some remarks upon the lack of particulars as to profit obtained, the cost of labour, &c. Apparently his desire for further information would have been satisfied to some degree had Mr. Louis been aware of the answers given by the inventor to Mr. Sulman. Mr. Cooper spoke briefly on the term "nascent chlorine," as used in the paper, and was afterwards answered by General Webber, who explained that sodium chloride was essential to the process for reducing the resistance of the electrolyte.

General Webber was then called upon to reply, and he did so, commencing by remarking that there was no reservation to the pleasure offered him by the observations of all the speakers. The paper was intended to consider the scientific, and not the commercial side of his subject, and chiefly was he concerned with the electrical side of the question. The fact that what he had dealt with was an electro-chemical process, was his reason for laying his paper before electrical engineers. If electricity were of no use, his paper was one to be brought only before mining engineers; but in bringing it under the notice of the members of the Institution, he desired to direct attention to the assistance that electricity afforded to an industry, the immense extent of which was perhaps not generally or fully realised. He thought that the younger members would do well to study the question as it fell to them to carry it on.

The replies to the criticisms in the discussion were complete and interesting. Briefly summarising what was said in a few lines, the author pointed out that the MacArthur-Forrest and Siemens-Halske processes were for the treatment of tailings; the methods for dealing with slimes had only quite recently approached practical solution. Three processes had generally to be employed:—Concentration, treatment over amalgamating plates, and finally with cyanide and deposition of the tailings. The descriptions of many processes failed to give any idea of the time occupied or the space required by the plant. The costs were difficult to give where labour is a factor that varies everywhere, and this factor alone may range from 2s. a day in one case, where a given plant is considered, with Kaffir hand labour up to 10s. or 12s., where white labour is employed. Messrs. Sulman and Teed were twitted with not giving any costs or scientific details of their own processes, which is a percolation one pure and simple. The cost of the Pelatan-Clerici process is governed by local questions; the variations for different classes of ore are effected by altering the length of time and quantity of chemicals.

Turbidity must be absent in the Siemens and Halske process, and the same condition is essential to success in all circulation processes: a great many more than those mentioned have been invented, and even put to work.

The president, Mr. J. W. Swan, followed General Webber with a few remarks that were useful in giving those present who were not metallurgists, a clear idea of the difference in processes. Thus the one before the meeting was intended for the amalgamation of gold that had not been brought into solution, its main object being to put the gold in a condition favourable for being taken up by the mercury. On the other hand, the Siemens-Halske process was one for the simple deposition of gold from a clear solution of gold already dissolved by cyanide.

Mr. Sherard Cowper-Coles then gave the description of his process for the production of projector mirrors, which was rendered all the more interesting by the use of the projection lantern, whereby a number of instructive slides were thrown upon the screen and explained to the audience by the author. In brief, the method consisted in depositing copper electrolytically on the back of a silver coating thrown down chemically on the surface of a glass mould of the desired form, the silver being afterwards covered by a coating of palladium to protect the silver from tarnishing. The silver and copper reflector is separated from the glass mould by heating in water to 120° F.

Mr. Grove thought the method was of particular value, as it enabled a projector mirror to be produced which did not require the excessive care in handling of an ordinary mirror, while it would probably be less effected by the bluish-white soot thrown off by the arc, and would, perhaps, be applied with advantage to the manufacture of the opaque screens used in projectors to maintain the parallelism of the beam by cutting off the direct rays coming from the front of the arc. General Webber conceived that this field of improvement might be of immense benefit to those who had to conduct the defence of our coasts in times of danger or under threat of invasion.

Mr. Mordey rose to protest against the assumption, implied in the observations of some speakers, that the Institution was not concerned with the "cost," or questions of cost. He thought that articles should be produced as cheaply as possible, and humorously remarked that while engineers are those who direct the forces of nature to the benefit of mankind, if the expense of any process is so great that man has nothing to eat, it is not much good to direct the forces of nature to his advantage. Mr. J. W. Swan congratulated Mr. Cowper-Coles very warmly upon his success in devising the process described, as he had considered the question years ago at the suggestion of Major Bagnold; but, foreseeing many objections to an electrolytic method, he had never ventured to combat them, and was pleased to find that such methods had proved so successful in the hands of the author.

The meeting adjourned with the interesting notification ringing in their ears that the next paper would be one by Mr. Binswanger-Byng on 200-volt fittings. The Institution has done well to procure papers on such "live" subjects as accumulator traction, electro-chemistry and now electric lighting. No doubt our friends—the station and contracting fraternity—will be glad to get back to a subject about which they have more to say than the extraction of gold—from ores.

THE "ALLAN" ACCUMULATOR.

THIS accumulator, manufactured by Allan & Adamson, Limited, has now been on the market for nearly three years, having undergone many severe and searching tests, not only at the company's works, but at the hands of others. The battery has quietly and steadily pushed its way forward, but the company decided not to court publicity in any special way until the most efficient methods of manufacture had been decided upon, and the battery had given satisfactory evidence of its durability.

These matters having now been firmly established, the company has no reason for further delay in bringing the accumulator more prominently before the electrical world; the more so, that recently a very important and valuable improvement has been made upon the plate, affecting its mechanical strength, and its efficiency as a support for the active material.

The plate is (as suggested by the last remark) of the pasted form, the paste or active material being supported in a hollow frame, both + and — elements being of similar construction. The hollow frame has lattices extending from edge to edge on both its sides, whilst the edges are perforated, and the paste is forced into these perforations to insure its more perfect support. Until recently the frame, cast in one piece, had the bevelled edge of its lattices on the outside, bevelled sufficiently to enable the frame to easily leave the mould, whilst the inner surface of the lattices were cast flat against the core; this form of lattice was deemed defective, as not securely locking the active material within the frame, and the attention of the management was directed towards *reversing* the lattices, whilst still casting the frame in one piece. This difficulty was ultimately overcome by a very ingenious method of casting (devised by Mr. Allan), which we are not at liberty on the present occasion to describe. The advantage of this improvement, however, must be at once apparent, as, by the new method of construction, the active material is preserved in one unbroken mass throughout the frame; that is, the frame supports the active material wholly from the *outside*. It is this peculiarity which confers upon this plate its freedom from *buckling*.

The composition of the paste is of such a nature as permits it to be made of almost any degree of hardness during formation without in any way lessening its power to discharge at very high rates; indeed, in this respect, it is claimed that the "Allan" accumulator is unusual, as its rate of discharge for three hours is said to be 1·5 amperes per pound weight of complete cell, whilst its average capacity in watt-hours, at a similar discharge rate, is equal to 9·0 per pound weight, the total ampere-hour capacity being equal to 6 amperes per pound weight, *also* of complete cell. A further idea of its capacity, weight, and size of a battery, may be gained by giving the following quotation from a tender which has just been submitted for use on a new electrically-driven cab:—

"Forty cells of 210 ampere-hours *guaranteed* capacity. The weight of these cells, complete, will not exceed 1,300 lbs., and they will measure outside 35 inches × 34 inches × 12 inches high."

The "Allan" accumulator makes strongly for traction. Its high capacity and discharging rate for its weight, its lightness, strength, durability, and immunity from buckling, all render it peculiarly adapted to this class of work.

Light and small, it can be more easily handled, and we all know that batteries, as a rule, suffer more in handling than they do in the actual work done by them. Aiming at perfecting their accumulator for traction work, the company is convinced that all other uses are being met at the same time.

The manufacturers consider the batteries admirably suited for every class of work, and having given them a thorough test for durability, are prepared to guarantee them and to substantiate the figures given.

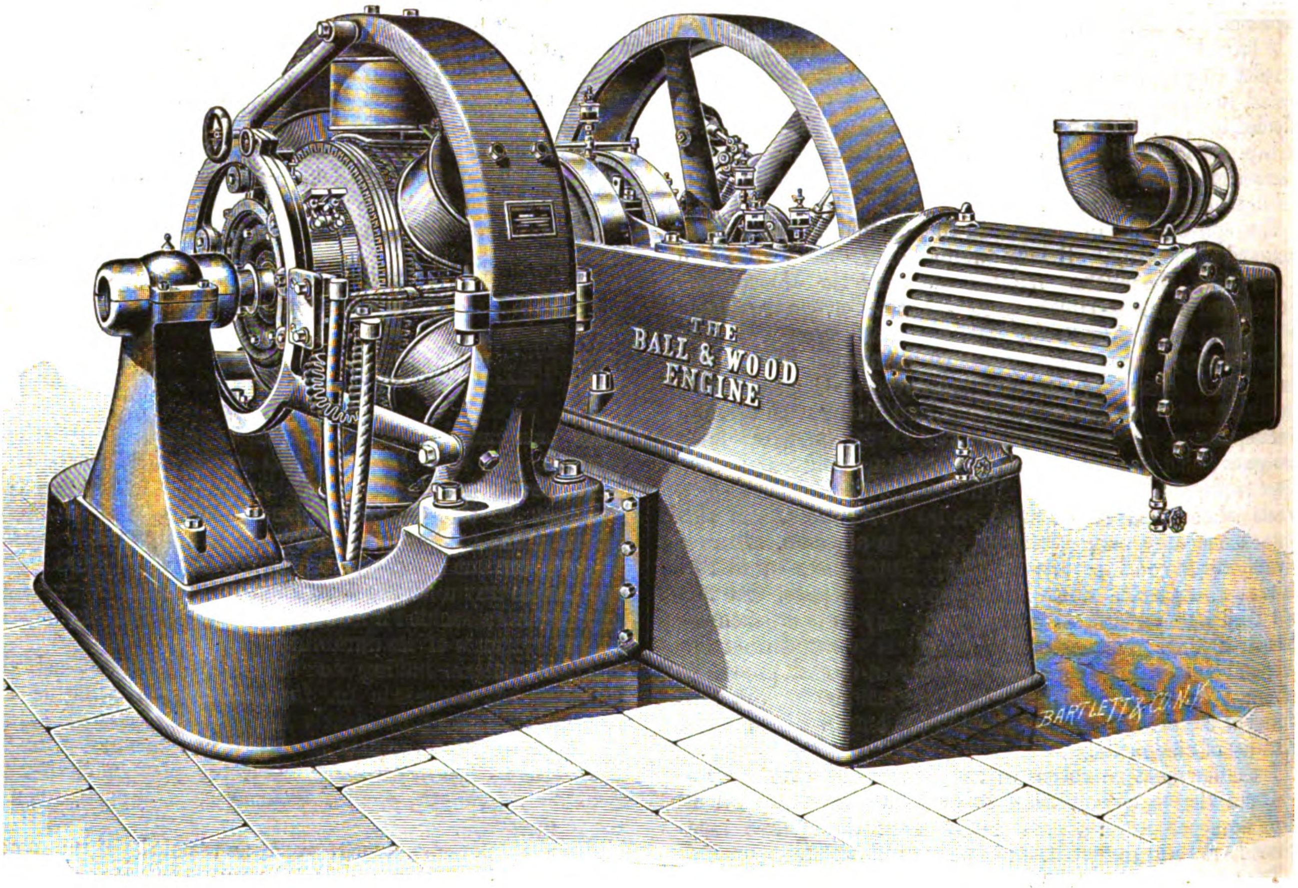
Several test sheets have been sent to us, all of which make out a remarkably good case for the "Allan" cell, but we have not space at our disposal to publish these.

We have, however, had an opportunity of seeing the process of manufacturing the plates, and of seeing several of the cells in operation, and there seems to be no reason why the merits claimed for this type of secondary battery should not be fully borne out in practical operations on a large scale. In any case electric traction experts will do well to fully investigate the claims made for this battery before deciding upon a choice of accumulator either for tramcars or other electrically-driven vehicles.

The North Metropolitan Tramway Company has had at least two sad experiences of the uses of secondary batteries on certain sections of its lines. Is it too much to hope that its enterprising and far-seeing managing director may see his way to yet another, and we trust commercially successful, venture?

THE BALL AND WOOD ENGINE.

One of the examples of the high speed American horizontal engine being introduced into this country by Mr. F. Nell (already so well known as a supplier of turbines), of 97, Queen Victoria Street, is that known as the Ball and Wood Engine. It is one of a box frame type, with over-hung cylinder and two fly-wheels with fly-wheel governor, and is claimed to regulate to 1 per cent. between abrupt changes of no load and full load. In this engine there is a peculiar slide valve which works between top and bottom faces. The ports are on the lower face, the steam entrance is in the upper face. The valve is in two parts, kept apart by the steam which is inside the valve, the two parts being joined by a telescopic sleeve. Exhaust takes place into the valve



chest. The face pressure is thus moderate and constant, and the wear even. The system of lubrication adopted is that of the oil pipe, clean oil from a reservoir being led to the parts through a filter and adjustable sight feed.

The Ball and Wood engine is one of those developed to its present perfection by the electrical industry, and in our illustration we show one of these engines directly coupled to a dynamo.

The sub-division of units has made the demand for economical engines of small power very large. Before the days of electric light, small-powered engines could not be obtained of economical type. The same tendency to use several units has spread to ordinary factories, where several small engines of good type are better than one large engine, probably owing to the great convenience they offer in running a department overtime when other departments are stopped.

In these engines there are double-disc counter-balanced cranks, the balance of the moving parts being thus direct and equally distributed on each side of the centre line. The two fly-wheels are outside the frame, and are made with a split boss, the split being radial only, and not diametral. When placed on the shaft, the boss is tightened by a stout through bolt, and opposite the bolt are two keys held tight by set screws. To put the wheels on their shaft it is only needful to use a small wedge to slightly open the boss so as to enable it to slip easily in its place. The governor, of fly-wheel type has the inertia weight and spring, and the inertia aids the centrifugal force. The weight arm is hollow, and has pockets for weights to vary the normal speed. The governor acts by moving the eccentric across the end of the shaft in such a way as to give a lead varying with the cut-off from a maximum at the latest point to zero, when the weights are in their extreme out position. Some idea of the powers of these engine may be gathered when we say that the 10 inches by 11 inches single cylinder engine run at 300 revolutions, will give 54 H.P. at 80 lbs. initial pressure.

The 16 inches by 16 inches engine at 250 revolutions, gives 211 H.P. at 100 lbs. initial.

Where an engine is wanted for direct connection, the bed or frame is made to suit the dynamo frame desired so as to obtain a harmonious combination.

In the catalogue before us, diagrams are shown from a 9 inches × 10 inches at 325 revolutions, which show a reduction of load from 300 to 75 amperes in 10 seconds. The diagram of each revolution is fairly closely traced as the load was taken off, and the governor action is made very plain.

The Ball and Wood Company do not confine themselves to small horizontal engines, or even to horizontal engines. They make also engines of vertical type and large size, for either direct connection, belt, or rope driving.

THE MEASUREMENT OF INSULATION RESISTANCE BY ALTERNATING CURRENTS.

For some time past, a rule has been in force in Germany which requires that the insulation resistance of any electric installation which is to be connected to the supply mains, shall be at least equal to $\frac{1,000,000}{n}$ ohms, when n is the number of lamps fixed; and, further, that the test shall be made with a pressure equal to that at which the circuit will be worked. In order to avoid the necessity of carrying about a battery capable of giving a testing pressure equal to the working pressure of the circuit, various methods have been suggested of making the test by means of current taken from the supply mains; and these methods, particularly in the case of alternating current supply, have lately formed the subject of articles in both German and French technical journals.

One of the methods proposed consists of connecting one pole of the supply mains through an alternating current voltmeter to the circuit to be tested, whilst the other pole of the supply mains is earthed; the insulation resistance being calculated, as in the case of direct currents, from the formula, $R = G.\frac{V - V'}{V'}$, where G is the resistance of the voltmeter, and V and V′ respectively the readings of the voltmeter when connected between the two poles of the supply mains, and between one pole and the circuit under test. Objection is taken to this method, because the resistance of the ordinary electro-magnetic voltmeter for alternating currents is so low that the instrument cannot be used to measure the insulation resistance of a circuit where the number of lamps fixed is small. This objection is, of course, an important one, but we do not think that accurate results would be obtained by this method, even on circuits of which the insulation resistance came well within the range of the voltmeter, unless this latter was specially arranged so that the non-inductive resistance in series with the working coils formed a very large percentage of the total resistance of the instrument. Again, although one pole of the mains might be earthed if each installation was fed by a separate transformer, there would be very great objections to the earthing of one pole of a low tension distributing network.

To get over the first-named difficulty of want of sensitiveness, an instrument has been devised by the Allgemeine Electricitäts Gesellschaft, in which the fixed coil is connected across the terminals of the supply mains, and is arranged to take a current of 1 ampere or more so as to produce a very strong field, whilst the circuit of the moving coil, which is of high resistance, is connected between one pole of the supply mains and the circuit to be tested. This type of instrument should certainly give much better results than the ordinary voltmeter, but the objection to earthing one pole of the supply mains still remains, and renders this particular method of testing inadmissible in many cases. A slight modification of the method of testing would render the earthing of one pole unnecessary, but it would at the same time reduce the testing pressure from that between the supply mains to the pressure between one pole and earth; and this might be anything between the full working pressure and half that amount, according to the condition of the distributing network. Of course, the objection to earthing might be removed by using a small equal ratio transformer to supply the testing current, but this would be nearly as cumbersome to carry round as the testing battery.

A bridge method has also been proposed and tried, the galvanometer being replaced by a telephone, and the battery by a connection to the supply mains, whilst the terminals to which the unknown resistance is usually connected, are joined up, one to the circuit under test and the other to earth. This method has been tried with a working pressure of 120 volts and a frequency of 50, but was not found sensitive enough to give satisfactory results, and although it is stated that accurate measurements could be made when the testing current was supplied by an induction coil instead of from the supply mains, the method does not appear to us to have any advantages likely to bring it into general use.

If any method is to be used in which the testing current is taken from the mains, we would suggest that the circuit to be tested should be connected to one pole of the supply mains through a non-inductive resistance, and that the potential differences between the terminals of this resistance, and between the supply conductor and earth should be measured by an electrostatic voltmeter. The insulation resistance of the circuit would be given by $R = r.\frac{V - V'}{V'}$ when r is the value of the non-inductive resistance, and V and V′ respectively the readings of the voltmeter when connected to earth and across the terminals of the resistance. The value of the resistance, r, must, of course, be such that it is at least equal to $\frac{R}{x - 1}$ if R is the highest insulation resistance to be measured, and x the ratio of the highest and lowest readings of the voltmeter.

ENCLOSED ARC LAMPS.

Since the introduction of the commercial arc lamp, says the *Electrical World*, in 1878 no improvement has been made in its development that can compare in commercial value with the enclosed arc principle. The use of the enclosed arc has practically revolutionised the arc light industry, and, says our contemporary, one of the earliest and most successful lamps of this character placed upon the market was the Jandus double enclosed arc lamp. This lamp, which is manufactured by the Jandus Electric Company, Cleveland, Ohio, has been before the public for the past three years, both in Europe and America. The Jandus lamp burns directly across the terminals of a potential circuit without waste of energy. This makes it desirable for a street lighting system where multiple circuits are used, and for an underground system it is particularly adapted, because lamps can be connected wherever necessary without the inconvenience of running connecting wires between pairs of lamps or installing two lamps where only one is needed, or wasting the energy of one lamp, as was necessary under the old system of connecting two lamps in series. For interior lighting, the economy and convenience of burning lamps singly cannot be over-estimated. The Jandus lamp has been highly endorsed by the Board of Fire Underwriters generally. Mechanically and electrically it differs greatly from any other lamp. The action of the lamp is extremely simple. There is only a single winding which forms the solenoid. The armature is held suspended in a strong magnetic field formed by the iron frame of the lamp, which surrounds the winding. The regulation of the lamp is maintained by the weight of the armature, which is considerable, opposing the pull of the magnet. When the arc becomes too long, from the consumption of the carbon, the magnet will weaken, owing to the decrease in the current flowing through it, caused by the increased resistance of the arc, and the armature will fall a little until the arc has regained its normal strength, and the current consequently restored, when the magnet will again hold the armature stationary. The armature is the plunger for its own dash pot, formed in a brass tube inside the coil. The carbon, extended by a tube or sheath, is inserted directly into the clutch, consisting of a pan-shaped piece, carrying four clutch rings, which fall by gravity and grip the carbon between the inclined side of the pan and the carbon. The clutch releases this and allows the carbon to feed when the armature has descended, until the clutch rings rest upon the releasing tube. This form of clutch allows the unequal sizes of the carbons and sheath to be fed through it with equal accuracy. The current is conducted to the carbon through a series of 16 contact rings, which are arranged in a circle and make a flexible contact with the carbon. One of the great advantages of the absence of the carbon rod is that the current is conducted from the mechanism directly to the carbon. The upper carbon is held concentric with the lower by the globe cap, which is centred by the guides on the bottom of the box enclosing the contact rings. The armature carrying the clutch is therefore the only movable part in the entire mechanism of the lamp, the absence of springs or adjustments being one of the most notable features. The yoke supports the inner globe and the lower carbon holder at its bottom end, where a ring admits the arms of the spider carried on the lower holder. This spider, by a turn to the right, locks the holder in position, and closes the electrical circuit through the lamps. The outer globe is secured to the yoke by a circular nut, and is closed, air-tight, at this point by means of asbestos gaskets. The Jandus standard lamp for outdoor service is provided with a waterproof case, and the terminal wires are led through water-tight rubber bushings, no hood being required. The rheostat is placed below the lower carbon holder inside the outer globe in a position where it will cast no shadow, and is thoroughly protected from the weather and readily accessible. In the lamp for inside service the rheostat is placed in a canopy at the top, where it can be readily adjusted by dropping the top half of the canopy. A cut-off switch is provided in the canopy. The Jandus lamp is claimed to embody the following advantages: Long life (the lamps burning 150 hours on a single half-inch carbon); lamps burn singly with economy on 110-volt circuit; perfect diffusion and uniform distribution of light; absence of flickering; practically noiseless in operation; fewness of working parts; decrease in cost of repairs, and small size.

THE PROTECTION OF ELECTRIC POWER TRANSMISSION CIRCUITS FROM LIGHTNING.*

By JOHN T. MORRIS, Stud.Inst.C.E.

The importance of efficiently protecting electric power transmission circuits from lightning is shown by the fact that in some of the earlier installations it was found more economical to shut down the generating plant than to run the risk of an armature being burnt out, or other similar mishap, during a severe thunderstorm. The danger lies not so much in the conduction of the discharge to earth as in the arc, started by the lightning, being maintained by the current. After demonstrating in a curve the relation between the sparking distance and voltage, the author shows that the discharges from which the line must be protected are of three kinds: (1) Those due to lightning actually striking the line; (2) the rush and surgings of electricity induced in the line; and (3) those due to slow accumulation of the charge. Discharges of the first kind are extremely rare, those of the third are occasional, while those of the second are the most frequent. The methods of preventing discharges from entering the circuit are described: at Niagara and Grünberg an earthed wire is stretched along the circuit a short distance above the conductors; and the means of providing opportunities for the discharge, after having entered the circuit, from passing to earth, are detailed. Lightning arresters may be divided into two classes: those in which the line is permanently connected to earth through a high resistance, and those consisting of a short spark-gap, one terminal being connected to earth and the other to the line. Examples of both types are explained, and the various methods of extinguishing the arc are dwelt with, typical instances of each being described. After dealing with the non-arcing properties of some metals, such as zinc, cadmium, antimony, bismuth, &c., the author proceeds to detail arrangements for good earths, and the methods, such as by choking-coils, of preventing discharges passing along the line to the power-house; the best positions of arresters in power transmission and tramway work are shown, and a description is given of a 15,000-volt 3-phase arrester and choking-coil rack. The author concludes by considering the number of arresters required upon a circuit: recent experience has shown that one per mile in sheltered places, and as many as twleve in exposed positions are necessary to ensure a reasonable degree of safety. The principles employed in some arresters were illustrated by experiments. Numerous specimens of different arresters used in power transmission work were exhibited.

* Abstract of paper read before the Institution of Civil Engineer Students, February 11th, 1898.

SOAMES'S MOTOR-TESTING BRAKE.

This brake, which is being introduced by the Davies Motor Company, is of extremely simple construction, and gives perfectly definite weighing of the torque on the pulley under test against ordinary dead weights. It consists of a steel lever working on knife edges, which can be raised or lowered by the hand-wheel at the top of the brake. Holes are drilled in the lever at equal distances from the centre, corresponding to the ordinary sizes of pulley in use. The centre of the brake is placed over the centre of the pulley, and from the two holes corresponding to the diameter of the pulley under test is suspended a piece of webbing, which passes round the pulley, as in the

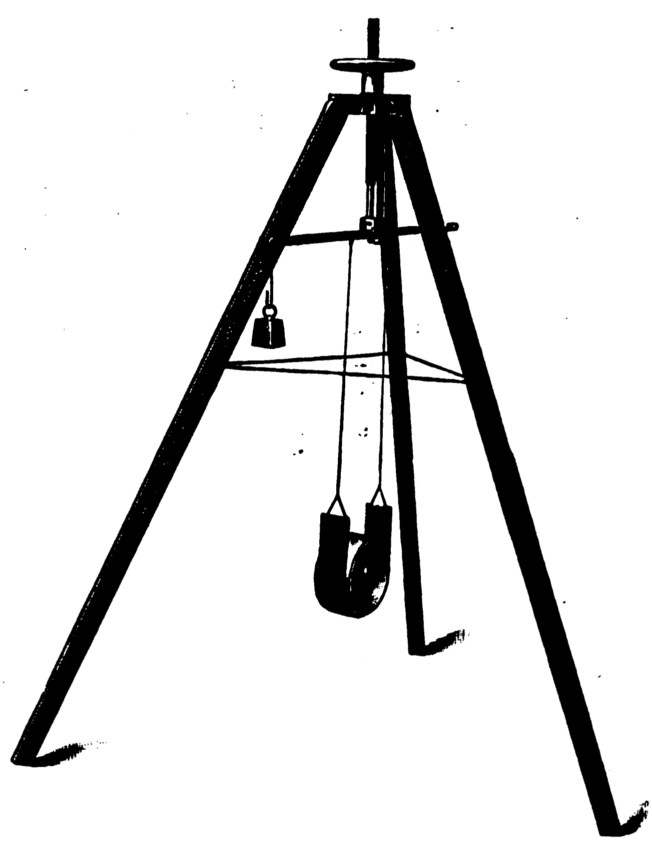


diagram. When the pulley is running, a weight, say, from ¼ to 30 lbs., is suspended on the end of the arm, as shown. The whole is then raised by turning the hand-wheel, tightening the belt on the pulley until sufficient friction is put on the belt to raise the arm to a horizontal position and keep it floating there; the speed of the pulley being taken at the same time. The usual constant, viz., $2 \pi L \div 33{,}000$, L being the distance of the weight from the centre, multiplied by the speed and the weight, gives H.P. direct. The size of the pulley, which should be perfectly smooth and flat, does not enter into the equation, so long as the distance between the holes in the arm is equal to its diameter; the band *must*, in all cases, be hung from two holes equidistant from the centre. It is stated that every reading can be repeated with absolute certainty, and that each one does not take more than 10 seconds at the outside.

HORSE-DRAWN CABS v. ELECTRIC CABS.*

The actual expenses of operating vehicles are very difficult to obtain in this country, both the costermonger and the railway director displaying a suspicious reticence when asked for information, which is not a little amusing. Our French contemporary, *La France Automobile*, has, however, succeeded in obtaining such information as is applicable to Paris, and we reproduce it here as being an eminently instructive comparison. Moreover, we think that the prices do not differ greatly from those ruling in London:—

Daily Cost of a Horse and Cab.

	Francs.
General expenses	0 53
Financial expenses	0.30
Tickets (cabman's)	0.01
Apprenticeship and sundries	0 05
Provident fund	0.07
Fire insurance	0 02
Lighting of carriages and depôts	0.11
Heating " "	0.02
Water	0.03
Syndicate expenses	0.05
Accidents and damage	0.35
Rent of depôts	1.05
Depôt staff and employés	0.99
Rates and taxes	2.26
Food, shoeing, and wear and tear of horses	6.65
Renewing and wear and tear of rolling stock	2.74
Wear and tear of property	0.21
12s. 4d. =	15.44

Daily Cost of an Electric Cab
(The number of carriages being equal in the two cases).

	Francs.
General expenses	0.17
Financial expenses	0.08
Tickets (cabman's)	0 01
Apprenticeship and sundries	0 05
Provident fund	0.04
Fire insurance	0 01
Lighting of carriages and depôts	0.05
Heating " "	0.01
Water	0.06
Syndicate expenses	0.05
Accidents and damage	0.24
Rent of depôts	0.35
Depôt staff and employés	0.50
Rates and taxes	1.50
Electrical energy and accumulators	2.20
Renewing and wear and tear of stock	2 74
Wear and tear of property	1.07
7s. 4d. =	9.13

Allowing for an under-estimate there is still a large balance in favour of the electrical cab.

BUSINESS NOTICES, &c.

Announcement.—Mr. S. Harrison, of Wigan, informs us that the delay in the execution of orders, occasioned by the recent fire is at an end, and that he is now in a position to give prompt delivery. He has, moreover, secured larger premises at 73, Wallgate, Wigan, to which the workshops and showroom will be transferred as soon as the necessary alterations are completed.

Business Announcement.—Messrs. Reed & Jenkins have opened a showroom at High Street, Bristol, and are generating their own current by means of a Silvertown dynamo driven by a Crossley gas engine. They are agents for the Stewart enclosed arc lamp.

Dissolution of Partnership.—Messrs. J. McLellan and G. J. Wells (John McLellan & Co., electrical engineers, 19, Station Road, Blackburn), have dissolved partnership from May 31st, 1897. Debts to be attended to by J. McLellan, who continues the business under the old name.

Liquidation Notices.—Mr. J. H. Thornton, of 2, Warwick Street, Regent Street, London, W., liquidator of the National Company for the Distribution of Electricity by Secondary Generators, Limited, gives notice to creditors that they must send notes of their debts or claims, and the usual particulars, to him on or before Tuesday, March 15th.

Mr. R. H. Marsh, of Ethelburga House, Bishopsgate Street Within, E.C., also gives notice that creditors of the Crompton-Howell Electrical Storage Company, Limited, must send to him as the liquidator, particulars of debts or claims, on or before March 25th.

Creditors of the Electrical Traffic Syndicate should send particulars of their debts or claims and the usual information to Mr. Maurice Jenks, 6, Old Jewry, E.C., liquidator, by March 26th.

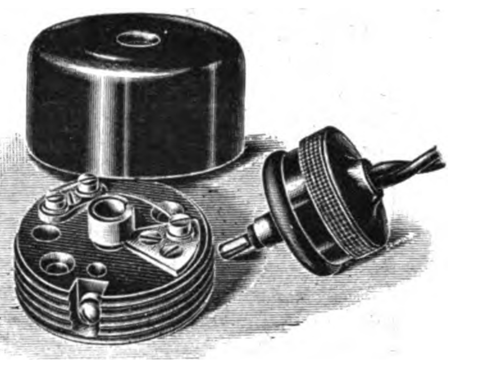
Concentric Wall Connections.—Mr. A. P. Lundberg sends us a sample of the "Gem" concentric wall connection, which he is just putting on the market. It is claimed to be simple in construction, small in size, and neat in appearance. Safety is claimed as one of its good points, as the brass parts of opposite polarity are well separated, and on this account wilful short-circuiting is made a



more difficult matter; the small hole in the cover (the plug being only $\frac{1}{4}$-inch diameter) is also an advantage. In outside appearance it closely resembles the "Dot" two-pin wall connection, which is in great demand, and can be fitted with similar varieties of covers and plugs as that pattern. It is only $1\frac{3}{4}$-inch diameter, and $1\frac{11}{16}$-inch height over all when plug is in connection with socket part. A long fuse is provided for, if such is required, and all plugs and sockets are made interchangeable.

Electric Clock-Switch.—A patent automatic electric clock-switch (Wheatley, James & Browne's patent) is being placed upon the market by Messrs. James & Browne, 39, Victoria Street, S.W. The instrument is specially designed for shop window lights, street lamps, advertising signs, &c. Its object is to automatically switch "on" and "off" at any desired time, the weekly winding of the clock being the only attention necessary. It is fitted with a quick make-and-break mercury switch, which has been found to work thoroughly satisfactorily both on arc and incandescent circuits. The mechanism involving the patent is very simple, though reliable. A single transmission wheel connects this mechanism with the clock, which is a pendulum movement. The instrument is enclosed in a painted iron case, and the dials are covered by a circular bevel glass in polished glass rim. For outdoor use it is enclosed in a dust-tight, damp-proof case, which can be fixed either in the base or attached to any lamp standard.

Electro-Chemistry and Water-Power Utilisation in Switzerland.—A company is in course of formation at Berne, with a capital of £80,000, to be known as the Electro-Chemische Industrie Gesellschaft, to put down plant to utilise certain available water-power, and to erect an electro-chemical factory near Thusis.

E

Electric Lamp Carbons in Canada.—It is reported that new works for the manufacture of arc lamp carbons by a special process are about to be established at Brockville, Ont.

Fire Alarms.—The houses of the members of the fire brigade are to be connected by means of electric alarms.

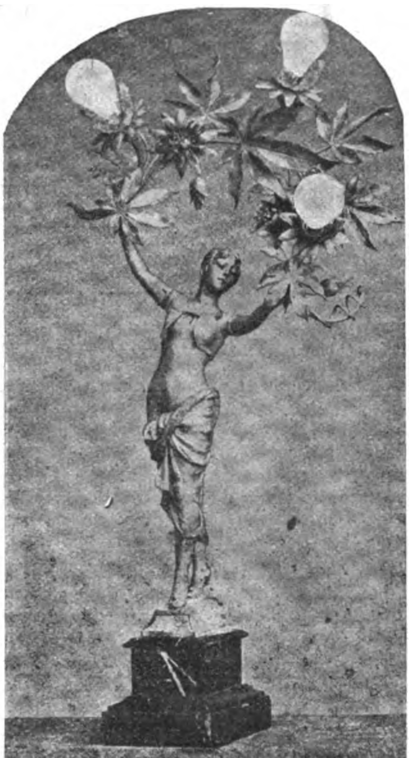
Foreign Cable Agency.—A first-class London firm, well connected with the electrical trades, is required to represent a foreign cable factory in England and British Colonies. Applications are to be addressed to K. E., 763, care of Rudolf Mosse, Cologne, Germany.

Harrison Coles & Co. v. Radford.—At Wandsworth County Court on Monday, Messrs. Harrison Coles & Co., sued Mr. Joyce Radford, of the Station Hotel, Richmond, for the cost of installing the electric light. The case was settled by defendant agreeing to pay £18 provided the work was done satisfactorily.

Institution of German Electrical Engineers.—The annual report of the Berlin Elektrotechnische Verein states that the number of members in January was 2,444, of whom 555 were resident in Berlin. As compared with January, 1897, this shows an increase of 371 members.

King's College Engineering Society.—At a general meeting held on Friday, February 11th, Mr. J. D. L. Bradwell read a paper on the "Manufacture of Incandescent Lamps." The author, commencing with an account of the parchmentising process of making filaments, went on to describe the different processes of mounting, and the uses of flashing; he then concluded with a short description of the method of making the bulbs, and sealing in the filaments.

Krupka & Jacoby.—We have received from Messrs. Krupka & Jacoby a set of illustrations of figures and wall decorations for electric lighting, of which we give an example, as the showrooms



of the firm at 62, Watling Street, are now stocked with a great variety of this special class of goods; those who need fittings of an ornamental character should not omit to pay them a visit, for the designs are extremely beautiful and artistic.

Lists.—The Phœnix Glass Company, of New York (London representative, Mr. A. L. Gibson, 4, Queen Victoria Street, E.C.) sends us a list of the Davis Indicating Globe. This is a globe in the shape of a hand, with a finger pointing to "office," "exit," &c., these words being on the back of the hand in black. The globes are made in opal, ruby, or flesh tint.

Messrs. Green & Boulding, of Featherstone Street, City Road, are sending out a list dated February 1st, 1898, giving full details of the Buffalo automatic injector, also some notes of the "Shipman" engine, Tripp metallic packing, &c.

Messrs. Price & Cornell, of 15, Victoria Street, S.W., have issued a list giving an illustrated description of the Westminster gas engine ("Otto" principle). Prices and particulars of single cylinder horizontal engines, from 2 to 30 H.P., are given, also of small horizontal motors ½ and 1 H.P., and vertical motors ¼ and ⅜-H.P.

Lloyd & Lloyd v. D. and W. Henderson & Co.—In this action, which has already been briefly reported in the Electrical Review, Sheriff Strachan has issued an interlocutor ordering an opinion of English counsel to be taken on the question. It will be remembered that plaintiffs sought to recover from defendants £600 as patent royalties for years 1895, 1896, and 1897. Pursuers hold letters patent in the United Kingdom for the Benardos system of electric welding, and at pursuers' request, they allege they had prepared a license to use the invention. Defenders delivered license again to pursuers signed by A. P. Henderson, for self and partners. The pursuers contend that by the law of England there is continuing liability for the total royalties to the end of the patents amounting to £2,600, less £400, already paid by the defenders. The defenders refuse to pay further royalty on the ground that there was no completed agreement, and that they had ceased using the invention.

Lyell v. Davies.—Judge Lumley Smith, Q.C., delivered judgment in this case at the Westminster County Court last Saturday. The plaintiffs, Messrs. Lyell & Co., electrical engineers, had an order for a frame in which the portraits of King Oscar and the Queen of Sweden were to be enclosed. They were fitted for the electric light, and were to be used in the decorations in Stockholm on the occasion of King Oscar's Jubilee. The frame was handed to the defendants with instructions to ship it by a certain boat for delivery at Gothenburg. They missed the boat, and on its arrival no artists could be obtained to paint the portraits, and the frame was therefore refused. Had it gone by the boat arranged for, it would have gone through all right. His Honour found that defendant undertook the risk knowing all the circumstances, and there would be judgment for the plaintiff for £18 with costs. Leave to appeal was given.

Packing Export Goods.—In connection with our recent comments on the necessity for more careful packing of machinery for foreign parts, we note from a paragraph in the *Times* that Germany attributes a good deal of its success abroad to the care which is given by manufacturers to packing and transport. The latest report from the British Legation in Munich contains some observations on the great importance of packing goods in such a way as to set them off to the best advantage, and of the improvements made in Germany in this respect during the past few years. Ten years ago German consular reports contained numerous complaints of defective packing and arrangement; but this has now been altered, and the Germans are said to surpass the French in the tasteful and suitable manner in which they present their wares to foreign buyers. The requirements of distant countries in regard to packing are carefully studied. The various methods of transport after arriving at the ports of discharge are known and provided for, as well as the provisions of the different tariffs, so that goods may be packed in such a way as to pay as little duty as possible.

Rochefort-sur-Mer Exhibition.—An international and colonial exhibition will be held at Rochefort-sur-Mer from June 1st to October 1st, 1898. The exhibition will be established on the Esplanade and the Roz-Bry Square. All the products of commerce industry, marine, and the fine arts will be admitted, and metallurgy, mechanics, and electricity will be special features. For all further particulars, apply to La Mairie de Rochefort-sur-Mer.

"Scientific American" Catalogue.—We have received from the publishers of the *Scientific American* (361, Broadway, New York), a cloth bound copy of their new *Scientific American Supplement* catalogue, giving, in carefully arranged form, titles of articles which have appeared in that paper on variety of subjects of scientific interest. The list is a good index, reference being made to 10,000 of the more important articles.

Scottish Cyanide Company.—We reproduce the following from the *North British Daily Mail*:—"The Scottish Cyanide Company will begin operations in a fortnight at their works at Leven. The process patented by Mr. Reymond, of Edinburgh, is purely electrical, the clay thereby being heated in its entirety, whereas by the old method this could not be secured. The electric plant is the best and most valuable laid down in the kingdom, and its cyanide of potassium will be put on the market at a much lower rate than presently secured. The capital of the new company is £200,000."

Smoking Concerts.—On Friday last, at the Grosvenor Hall, Buckingham Palace Road, between 300 and 350 employés of Messrs. Drake & Gorham, and their friends, attended a smoking concert, and a very pleasant evening was spent. Mr. Drake stated that 1897 had been the firm's record year in turnover, in spite of increasing competition, and that during the past 12 months £1,000 had been distributed among the employés in the form of bonuses.

A smoking concert of the drawing office staff and others employed at the Electric Construction Works, at Bushbury, was held at the Swan and Peacock Hotel, on 5th inst.

Water-Power.—The subject of water-power utilisation for electric lighting installations is an attractive one, and it will interest our readers to know that Mr. Alph. Steiger has just supplied and erected a new turbine plant which utilises a fall of only 2 feet, and develops 40 brake horse-power, for Mr. A. J. Taylor, of Strensham Mills, near Tewkesbury. The plant has just been most successfully started. There are probably not a dozen turbine plants in the world utilising such a low fall; but the success claimed in this instance shows that even low falls, of which there are plenty in this country, can be turned to good account.

Workshop Lighting.—Messrs. Robey & Co. have put down the necessary plant for lighting the workshops, offices, and other buildings, of Messrs. Wm. Pattinson & Sons, builders and contractors, at Ruskington.

ELECTRIC LIGHTING NOTES.

Aberdeen.—Prof. Kennedy was in Aberdeen on Saturday, and conferred with the Gas and Electric Lighting Committee *re* extensions of electric lighting to the West End, the utilisation of dust, and the proposed electric tramways. The professor will report. It is proposed to light the West Church by electricity.

Adenshaw.—The District Council recently conferred with the Manchester City Council *re* electric lighting, and the latter body offered to lay cables to supply such places as Adenshaw at the same price as Manchester residents pay.

Ashton.—The Council has approved of a design of arc lamp pillar, with incandescent lamp brackets, submitted by Mr Clirehugh. A tender has been accepted.

Ballymena.—Immediate steps are to be taken to have the town lighted electrically. The clerk to the Commissioners is to get information from English towns as to the systems.

Bermondsey.—The Electric Lighting Committee has been empowered to obtain a further report from Mr. Manville, dealing with the proposal to combine dust destruction with the electric lighting scheme.

Blockley.—On Tuesday last the small plant for street lighting was inaugurated. Messrs. T. Parker, Limited, supplied the dynamos (one for the public, and one for private supply), one being worked by a 13-H.P. turbine, and the other by a 10-H.P. vertical engine. There are 28 lamps in the streets. The cost has been defrayed by public subscriptions. Major Spencer (whose wife switched on the current) replying on her behalf, said that nine years ago the village adopted electric street lighting, and it continued until the Blockley Electric Light and Manufacturing Company dissolved three years ago, since when oil lamps had been used. Mr. H. N. Warburton was the electrical engineer for the work.

Cheltenham.—The electrical engineer has reported that the two new boilers had been erected and tested with satisfactory results, and that the first 220-kilowatt steam alternator would be ready for steam trials on February 9th. Mr. Waghorne stated that the electrical engineer estimated that the delay in the supply of machinery caused by the engineering dispute had involved the loss of something like £1,000 to the electric light revenue.

Cordoba.—From an article in a Buenos Ayres paper, we gather that the electric light and power works for Cordoba, Argentine Republic, are in so advanced a state, that in the course of a few weeks supply may be commenced. Turbines and dynamos are in position at Casa Bamba. The cables are completed to Cordoba, 22 kilometres in length, and some of the mains in the city as well. The company utilises the power of the river fall between Dique de San Roque and Mal Paso, on the Rio Primero. At Casa Bamba a tunnel, 90 metres long, and 3½ metres diameter, has been made through the hill, connecting the two extremities of a great bend in the river. Water is conveyed from the tunnel to the turbines by a 2-metre iron tube. When further plant is put down to the extent provided for, there will be 5,000 H.P. available. Current is conveyed by overhead conductors at 10,000 volts. From Casa to Cordoba there is a line of posts bearing three 9-mm. copper wires, and three wires for protection from lightning. At the Casa Bamba station transformers raise the voltage, and near the Observatory it is reduced to 2,000 volts, and subsequently to 210 and 115 volts respectively for power and lighting of consumers' premises. The general manager of the Electric Light and Power Company at Cordoba is Mr. Theophilus Greenwood. The company has numerous applications for current.

Country House Lighting.—The Grove, Witham, has been lighted by electricity for Mr. Percy Laurence. Messrs. Laurence, Scott & Co. supplied the plant, and Messrs. Strode & Co. carried out the work. There are 200 lights in the mansion and other buildings.

Lord Wantage has given the order to the National Electric Free Wiring Company, Limited, for supplying and erecting a complete installation for electrically lighting "Downs" House, near Wantage. The installation comprises steam engine, boiler, dynamo, storage batteries, switchboards, mains, house wiring and fittings. The wiring is all to be on the "patent Twin system," owned by the National Electric Free Wiring Company, Limited.

Coventry.—The monthly return of the electric light department shows an increase over the corresponding period last year. For the past few months the returns have shown a steady increase.

Crieff.—On 7th inst. the Town Council met in private to consult with Mr. R. Frederick Yorke, A.I.E.E., as to the proposals he has made in regard to electric lighting for the burgh. Mr. Yorke thinks though £8,000 would, in his opinion, be necessary to carry out the scheme he proposes by water power, the working expenses would be nothing approaching the outlay if steam power were to be used. He would propose to convey the current from the Turret or Barvick Falls to Crieff by overhead wires. He is of the opinion, if a local company could be formed for carrying out the scheme, the town would be relieved of all responsibility in the way of raising capital, &c.

Greenock.—Last week we stated that Mr. Tighe, of Paisley, was being consulted by the Commissioners on the electric lighting question. This should, of course, be Mr. Teague, of Paisley.

Hartlepool.—In connection with the proposal to combine dust destructors with electric lighting here, a Corporation deputation visited Leyton last week to inspect the destructor there.

Hyde.—The Council is to apply to the Local Government Board for a further loan of £1,000 on the Technical School account for electric lighting and other purposes.

Ipswich.—The electric lighting order having been obtained, various proposals were before the Town Council recently, as to what should be done next. One motion was, that the Electric Lighting Committee be re-appointed, with instructions to proceed with the necessary works at a cost of £36,200; but ultimately an amendment, requesting the committee to carefully consider the offers received by private parties for the purchase of the order, was carried.

Kettering.—Letters have been received from the Municipal Electric Supply Company and the Electric Extension Company *re* electric lighting. Further consideration has been deferred by the Council for three months until the new Council is in office.

Kingston.—The fourth annual report of Mr. J. E. Edgcome, borough electrical engineer, shows that after payment of all the works' cost for generation of electricity, maintenance, and repair of machinery and mains, &c., there remains a balance of £867 19s. 9d., as compared with £301 3s. 1d. for 1896. This sum is sufficient to pay the interest for the year on the capital expended on the undertaking, leaving a balance of £43 12s. 1d. towards the repayment of the principal.

Leeds.—The Yorkshire House-to-House Company, and representatives of the Corporation, conferred together on 8th inst. respecting the proposed purchase of the undertaking by the municipality. It is probable that the whole matter will be thrashed out before the Local Government Board inquiry, to be held in a week or two.

Liverpool.—The Much Woolton Urban Council is proceeding against the Liverpool and District Electric Lighting Company for having caused a smoke nuisance at the generating station at Gateacre.

London.—Mr. T. W. E. Higgens, surveyor to the Chelsea Vestry, has drawn up a report with regard to the Metropolitan Electric Supply Company's Bill before Parliament, in so far as it affects the parish of Chelsea. He states that the company are supplying electricity in various areas, and, being unable to acquire land for larger generating stations within the areas supplied by them, have purchased a site in Willesden and Acton, upon which they are erecting a generating station, and they seek Parliamentary sanction to convey electricity from this station to Amberley Road, Paddington, by means of two lines of cables, one laid under the towing path of the Grand Junction Canal, and the other under the roadway of Harrow Road. The Chelsea surveyor thinks that the Vestry should oppose the laying of any mains in Harrow Road, unless the company will undertake to supply electricity for public and private purposes at Kensal Town at a cost of not more than 4½d. per unit.

Lowestoft.—At the last Council meeting Mr. Fry, chairman of a Special Committee, reported in favour of the Horsfall destructor, of high temperature and forced draught. A rough estimate of the cost was £3,000, which would effect considerable saving on the present system. Smith's Marsh had been practically decided on as the site of the electric station, and there would be plenty of room there for the destructor. The question was referred to the Sanitary Committee to obtain tenders and apply for a loan for the combined scheme.

Lynn.—After receiving a note of the terms of several consulting engineers for reporting and advising *re* electric lighting, the Corporation has appointed Prof. Kennedy.

Newmarket.—A local company has been formed to take over the electric lighting order which Messrs. Edmundson, Limited had agreed to purchase from the Council.

Pembroke.—Mr. Robt. Hammond explained his electric lighting scheme to the Commissioners on 7th inst., and the Electric Lighting Committee was afterwards instructed to proceed with the scheme, the estimated cost of which is £32,500. The proposed compulsory area includes four miles of lamps, and the scheme provides for 7,500 lamps, though the station chimney and buildings will be large enough for plant for 15,000 lamps.

Peterborough.—The Local Government Board inquiry into the application for a £15,000 electric lighting loan for the Council was held at the Guildhall last week. The inquiry lasted three years.

Plymouth.—An electric lighting plant, comprising a Taunton dynamo and Crossley gas engine, has been put down for a new *café* at 45, George Street. An electric motor is to be employed for coffee grinding and roasting machinery.

Poplar.—We learn that at an expenditure of about £50,000, the District Board of Works have resolved to adopt electric lighting.

Portsmouth.—Owing to the collapse of the engineers' strike, Alderman G. Ellis, J.P., estimates that within six weeks or two months there will be sufficient current available to supply 10,000 extra lights. A member advocated dust destruction in connection with the installation.

Sheffield.—The *Sheffield Independent* for February 10th gives a complete copy of the terms of the agreement entered into by the Corporation and the Electric Light Company for the purchase of the undertaking, to which we briefly referred last week. The company receives £213 8s. for every £100 share originally invested, and in addition £70,000 for stock and stores in hand and recent capital expenditure.

It is stated that the solicitor acting in the interests of the Electric Light Company has forwarded a letter to the Town Clerk, stating that, having regard to the insinuations and untrue statements made at the last Council meeting, the directors have decided that the terms of purchase under discussion between the parties shall remain in abeyance for the present. The directors invite the Parliamentary Committee to inspect the minute books from beginning to end, and offer to supply all information with regard to the contracts, engagements, and liabilities of the company, in addition to full investigation of the figures mentioned in the terms of purchase.

The Parliamentary Committee, after considering the company's communication, expressed its opinion that the directors were fully acquitted of any improper secrecy or conduct in connection with the negotiations, and trusted that the terms would be accepted by the company.

Shrewsbury.—The provisional order has passed the standing orders of the Board of Trade, but a memorial has been lodged by six persons (all, or nearly all, large gas shareholders) against the purchase of the Shropshire Electric Light and Power Company's undertaking.

South Australia.—During the last session of Parliament in the colony of South Australia, an Act was passed in favour of the South Australian Electric Light and Motive Power Company, which gives to this company practically a monopoly of the electric light and motive power business throughout the colony. One of the promoters of the Bill was Mr. W. W. Crawford, M.I.M.E., C.H.E., A.I.E.E., the representative in Australia of Messrs. Johnson & Phillips, to whom orders for the Port Adelaide plant have already been transmitted. Mr. Crawford is a large stock holder, as well as a director of, and consulting engineer to the company. Messrs. Johnson & Phillips have now depôts at 91, Pitt Street, Sydney, and Brookman's Buildings, Adelaide.

Southampton.—The Electric Lighting Committee is to consider the subject of lighting the parks by electricity, in conjunction with the public thoroughfares. The plant is working to its full capacity, and no more consumers can be taken on until the end of May.

Taunton.—The Town Council will apply for a £10,000 loan for electric lighting extensions. Mains are to be extended in various parts, and a sub-station is to be erected at Rowbarton. The increased demand necessitates these extensions.

Mr. E. B. Thornhill, electrical engineer, reports that the lamp connections during the past quarter increased by the equivalent of 364 8-C.P. lamps, and orders were in hand for 480 8-C.P. lamps.

Torquay.—Trials are this week being made of the plant at the electricity works.

Wakefield.—The chairman of the Electric Light Committee visited Messrs. Fowler's Works at Leeds last week, and reported himself satisfied with the progress being made with the engines and dynamos, &c.

West Ham.—The Town Council has altered the rates of current from 6d. per unit for the first two hours and 4d. after, to 7d. per unit for the first two hours and 3d. after.

West Hartlepool.—The total amount of the electric lighting contracts given out, as stated under "Contracts Closed" last week, was £12,000. When the matter was before the Council, some members thought that the borough surveyor had not been consulted sufficiently in the matter, and that the recommendations of Prof. Kennedy should first have been submitted to him. However, the acceptance of the tenders was confirmed by the majority.

Weston-super-Mare.—The District Council is desirous of keeping the electric lighting business in its own hands, and the Weston-super-Mare Electric Light and Power Syndicate is also wishful in the same direction. The syndicate applied for an order annulling the powers granted under the 1891 municipal order, which had not been carried into effect. The Council drew up its objections to such a course, and expressed its intention of carrying out a scheme itself. Both parties have been in communication with the Board of Trade on the matter.

Wigan.—The Gas and Electric Lighting Committee is again going into the subject of electric lighting. At a recent Council meeting, Mr. Fyans made a long statement as to the progress being made in other towns.

Withington.—A sub-committee of the District Council has been appointed to enter into negotiations with the Manchester Corporation for a supply of electricity to the district.

Woking.—The Council complains that many of the electric lamps of the Woking Electric Supply Company give a light of less than 25 candle-power. A list has been sent to the company at its request.

Wood Green.—A letter from the Municipal Electric Supply Company, suggesting a supply of electricity for Wood Green, is in the hands of the District Council.

Worcester.—Statements were made at the City Council meeting recently, to the effect that the cost of electric lighting at the Market Hall was double what it was formerly for gas. In 1895 and 1896 the cost was £45 and £54 respectively for gas; but in 1897, for electric lighting, the cost was £112. It was stated to be the same at the Guildhall and Public Hall.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

Airdrie-Coatbridge.—The Coatbridge Council has discussed the arrangements come to with the representatives of the British Electric Traction Company to lay this line of tramways, and has decided to withhold opposition provided certain concessions are granted by the company.

Australian Electric Power Scheme.—The *Times* correspondent at Melbourne telegraphed on 12th inst. saying that Messrs. Horn and Bakewell, two leading colonists of South Australia, had left by the *Orizaba* for London, to place the Great Western Railway and Electric Power Company before English capitalists. The company possesses valuable concessions of land, together with the right to construct a railway connecting Hobart with the Mount Lyell and Zeehan district, in Tasmania.

Bristol.—The Town Council has referred back to the Sanitary Committee its report upon the electric traction proposals of the Bristol Tramway Company. This report approved in principle the extensions of the company's system proposed, but suggested that certain routes might be altered with advantage. It, however, pointed out that the new lines were 7½ miles in length, and for half the distance there was not the requisite width of carriage way, 9 feet 6 inches, between the rail and kerb, and many frontagers had objected. The point, however, to which the report took special objection was the endeavour of the company under their Electrical Power Bill to arrange the mode of traction with the Board of Trade without consultation with the Council. The report proposed that the Committee oppose both Bills, although meanwhile negotiating with the company. Opposition to this view was expressed in an amendment which, after much debate was carried by 36 votes to 29. "That the report of the Sanitary Committee and the two Bills of the Tramway Company, be referred back to the Sanitary Committee for negotiations; that meanwhile a petition be presented against the Electrical Power Bill, but that the consent of the Corporation be given to the promotion of the Extension Bill conditionally."

Canterbury—Herne Bay.—A Dover paper says that a movement is on foot in Canterbury for establishing an electric tramway service between there and Herne Bay. The two towns are at present connected by a 'bus service.

Cardiff.—The Electrical and Lighting Committee propose sending a deputation to the Continent to inquire as to what is the best system of electric tramways for Cardiff. The proposal was only carried by three votes to two, and we suppose the matter has yet to come before the Council.

Dublin.—Before Mr. Justice Murphy and a special jury in the Dublin Nisi Prius Court, on 7th inst., Mr. Robert Forrester claimed from the Dublin United Tramways Company £500 damages for personal injuries sustained. When the plaintiff got on the platform of a car it gave a sudden lurch and he fell off, sustaining a cut and becoming unconscious. Defendant company declared that the car was at a standstill when plaintiff fell off. Judgment for defendants.

A special meeting of the Corporation was held on Wednesday, for the purpose of dealing with the report of the sub-committee appointed to deal with the plans of the Tramways Company for the introduction of electric traction within the city.

Edinburgh.—It has been referred to a Committee to report upon the advisability of constructing an electric tramway from Preston Street *viâ* Dalkeith Road and Niddrie Road, to Joppa and Portobello, returning by Meadowbank and Waterloo Place. As Prof. Kennedy is being consulted on various other matters this, too, is to be laid before him.

Electric Power Distribution Schemes.—Several of the other municipal authorities whose districts are affected by the two electric power schemes which have been occupying a good deal of attention of late, have resolved to oppose the proposals.

Electric Railway between Frankfort, Homburg, and Saalburg.—The Light Railway Company, Lenz & Co., of Stettin, has submitted to the municipal authorities at Homburg a project for constructing an electric railway, running from Frankfort-on-the-Main, through Homburg and Dornholzhausen to Saalburg. It is proposed in this scheme to run the line along the highways wherever possible.—*Elec. Tech. Zeit.*

Electric Railway between Glauchau, Meerane, and Crimmitschau.—The preliminary work for the construction of this electric railway has been commenced. The main line will run through the streets and highways to Crimmitschau; a branch line going from an intermediate station (Dennherits) to Meerane.

Electric Tramways at Frankfort-on-the-Oder.—The electric street railway, built by the Allgemeine Elektricitäts-Gesellschaft at Frankfort-on-the-Oder, was opened on January 22nd.

Electric Tramways at Liegnitz.—These tramways, constructed by Felix Singer & Co., were taken over by the local authorities on January 18th, and were opened a few days later with 14 motor tramcars running on the line.

Egypt.—The Compagnie des Tramways d'Alexandrie has just secured a concession for another electric tramway in Alexandria, which will bring up the length of the electric tramways in that city to 25 kilometres.

Halifax.—Owing to the difficulty experienced in obtaining prompt delivery of materials, it is said to be very doubtful whether the whole of the system will be ready to be opened, as desired, on Easter Monday. The Electric Supply Association, however, have promised to supply sufficient plant and rolling stock to enable the Corporation to have at least one section of the tramways in operation by that date.

Hounslow.—Mr. Clifton Robinson appeared before the Hounslow District Council on 8th inst. and explained the details of the proposed electric tramway scheme which would touch this district. The Council, after discussion, gave its consent to the scheme, subject to certain conditions being fulfilled.

Introduction of Electric Traction in Berlin.—After the Berlin Horse Tramway Company received permission from the authorities to introduce electric traction, they set about the work immediately. In the first week of January the erection of the overhead conductor was begun, and by the middle of February the electric system will be working on lines from Alexander Platz to Schöneberg, and from Demminer Strasse to Kreuzberg. On these lines the mixed system of overhead conductors and accumulators will be employed. The overhead system on the first mentioned line will extend from Alexander Platz to Spittelmarkt at one end, and from Potsdamer Platz to the terminus at the other end. On the second mentioned line it will extend over the Demminer Strasse-Kreuzberg section, and the Bärwaldstrasse-Kreuzberg section. Electric traction will next be introduced on the Ringbahn, the conversion taking place early this year. On the lines from Lützow Platz and from Moabit to Charlottenburg, horse traction will be retained until October 1st this year. Permission has been given to the street tramway company to introduce electric traction before October 1st, 1898, an extension to January 1st, 1899, being granted if necessary. The company will not, however, be able to introduce as many accumulator cars as they require before October 1st, 1898.—*Elec. Tech. Zeit.*, January 6th, 1898.

Leeds.—The Leeds Tramways Company have, says *Daily Tenders*, adjourned for one month the question of providing the Headingley, Chapletown and Hunslet sections with a system of electric traction similar to that at Roundhay Park and Kirkstall.

Thirteen out of the twenty-two cars ordered for the Kirkstall-Roundhay electrical tramway are now running. This number of cars permits of a 10 minutes' through service. When the whole 22 cars are ready, there will be a 5 minutes service between Harehills Lane and the Cardigan Arms.

River Plate.—In December last "La Capital" electric tramway was inaugurated at Buenos Ayres. The length of line opened, says the *Review of the River Plate*, was 14½ kilometres, which will bring the suburbs of Flores and Caballito into direct communication with the southern and central districts of the city. The electric cars start from the Plaza at Flores, running to the temporary terminus at the corner of San Juan and Entre Rios, from which point passengers are conveyed in horse cars to the Plaza de Mayo, Boca and Darsena, combination tickets of the Capital Company being issued for the whole journey. The conversion to electricity of the existing line, between Entre Rios and Plaza de Mayo, is being actively carried on and will in a short time be completed, when a direct electric service from the Plaza de Flores to the Plaza de Mayo, and *vice-versa*, will be definitely established. The electric service from the Plaza de Mayo to the Boca will be opened early this year. The central terminus of the system is in the Plaza de Mayo, between Congress and the Government Houses, opposite the Bolsa, from which point the cars will proceed down Calle Victoria. The power station is at the corner of Comercio. The building covers 1,400 square metres, and is equipped with three vertical compound Ball and Wood engines of 450 H.P. each, directly coupled to 300 kilowatt Walker generators. Two of these units will be sufficient to supply current to all the cars that will be in operation on the line at one time, so that one unit can be kept in reserve. The engines have 30 inches × 14½ inches cylinders × 18 inches stroke, running at 175 revolutions per minute. They are fitted with Corliss valves placed in the cylinder heads. The admission valves are controlled by a Ball & Wood governor. There are four Stirling water-tube boilers of 250 H.P. each working at 140 lbs. pressure. Green's economisers and Conover's condensers with compound pumps are employed. The water system is very completely arranged. There are two Worthington pumps, either of which can supply all the water required by the four boilers. By means of a special system of piping either or both of the pumps may do the following service:—(1) Draw water from the city water service, (2) from a semi-artesian well, (3) from a large reserve water deposit, (4) from a waste water well. The water can be discharged (1) into the boilers direct, (2) into the boilers through the economiser, (3) the waste water into the sewer, (4) through a fire hose conveniently located in the boiler room. The power house is of steel, and is designed for an ultimate capacity of 20,000 H.P. Current from the power station is carried by an underground cable to Entre Rios, and then by trolley wires and a feeder cable overhead carried on poles. The return current from Entre Rios is also by underground cable, temporarily. The rolling stock will consist at first of 41 cars; and workshops for mechanical repairs, &c., have been erected. The cars will carry 52 passengers, 30 outside, 22 inside. They are equipped with two "General Electric 1,000" motors each. The entire rolling-stock has been built by the J. G. Brill Co., and mounted on Brill trucks, having been put together and painted in the tramway company's workshops. The track construction is most substantial. Johnson 9-inch 90-lb. grooved girder rails have been used, the rails being bonded with two classes of bonds, the Edison-Brown plastic bond, and the Syracuse soldered bond, and cross-bonded with copper wire every 100 metres. The feeders in the business districts are all underground. The poles are both wooden and iron, the latter being supplied by Morris, Tasker & Co., the H. W. Johns Company supplying the overhead appliances. Mr. Charles R. Thursby, managing director, superintended the construction of the line, and Mr. J. W. McCrosky is the chief engineer.

Staffordshire.—The Brierley Hill Council has approved the design submitted by the British Electric Traction Company for the trolley pillars for the electric tramways, subjected to the satisfaction of the surveyor.

Storage Batteries as Station Auxiliaries.—The Consolidated Traction Company, of Pittsburg, has recently installed two sets of storage batteries as station auxiliaries, one in one of its power stations, and the other at a point midway between the other three power stations; each set has a capacity of 500 ampere-hours. The result has been a considerable increase in the output of the stations; in a particular instance one set of accumulators in parallel with a 800-kw. generator, has enabled the company to obtain from this generator continuously for 24 hours an output of 1,100 kw. The total output of the four stations can be easily adjusted by means of accumulators, so that any one can be made to carry any portion of the load up to its capacity, the four stations are tied together by feeders; the actual economy in the resistance loss in the feeders by maintaining the voltage constant is very large. The results secured on this line have been so important that the United Traction Company has decided to abandon its present McKeesport station and substitute for it a storage battery station; the maintenance of this station has cost the company, on an average, about $7,200 per annum, most of which, it is thought, will be saved by the installation proposed.—*Electrical World*, New York.

Storage Battery Traction.—The equipment of the Ostend railway is on the electric accumulator system, the plant being established in the depôt of the local railway. The line, which was recently described in *L'Electricien*, is 3·1 kilometres long, and is virtually a circular road connecting the Kursal Boulevard, Rogier Station, and the Harbour. The plant includes one compound engine direct-connected to a Westinghouse dynamo, generating 135 amperes at 280 volts, and operating at 650 revolutions. The switchboard is of three white marble sections, with the usual instruments, and commands four accumulator-charging circuits with pressures varying between 240 and 270 volts. The charging of the accumulators is done upon a central track, so that the handling, both loading and unloading, is extremely easy of accomplishment. The complement of each car comprises 12 boxes of nine elements, having a capacity of 140 ampere-hours, at a 50-ampere rate. The charge lasts from three-quarters of an hour to two hours, according to the demand made upon the battery. As constant use gradually disintegrates the active matter of the positive plates, this is carefully saved in a tank, and eventually used for renewing the battery. This process is several times repeated before the frame finally becomes worthless, when it is recast. Each element is contained in an ebonite vessel, the nine elements being inclosed in a wooden trough, having two bands of copper for contacts. The carriages weigh 7,500 kilogrammes without accumulators or passengers, and have a capacity of 24 seats and 26 standing places. They have no imperial or deck seats. The carriages are lighted by six 16-candle-power lamps each, and are provided with two 18-kilowatt Westinghouse motors, each connected to an axle by reducing gears of one to five. The motors are regulated by a series-parallel controller with spark extinguisher. According to data obtained for three months of active service, the management claims that the expense of this line will be very much below anything so far known in this form of traction, the consumption of coal being shown to be but 1·45 kilogrammes per kilometer-car.

Stourbridge and Kinver Electric Railway Scheme.—On Tuesday, the Earl of Jersey and Col. Boughey, the Light Railway Commissioners, held an inquiry at Stourbridge respecting the proposal of the British Electric Traction Company to construct an electric tram line between Coalbournbrook and Kinver. Mr. Foley, one of the principal landowners had intended to oppose the railway, but he withdrew his opposition during the inquiry. In the result, Lord Jersey said that as regarded the preamble there was a case, and the Commissioners would be happy to recommend to the Board of Trade that the order should go forward. He, however, pointed out that many difficulties might have arisen had Mr. Foley not withdrawn his opposition so handsomely.

Sydney.—Mr. G. Fischer, an officer of the Works Department, recently returned from the United States, where he had been superintending the construction of some electric material for the George Street tramway. A Sydney paper says that the material that has been ordered for the department from the States is for the power-house at Ultimo. The department is also getting from the States 2,000 tons of steel rails. An effort was made to obtain the rails from England, but manufacturers there found it impossible to supply them with the higher proportion of carbon that was required. American firms, however, promptly agreed to provide the material of the desired quality, and the order was placed accordingly.

Swansea.—The Swansea Tramway Company, which has been negotiating for some years with the Swansea Corporation, have, says the *Western Mail*, now practically come to terms with another customer for the undertaking. A meeting of shareholders is to be held in London on February 25th for the purpose of considering the terms of an agreement, dated February 9th, 1898, between the Swansea Improvements and Tramways Company, and the British Electric Traction Company, for the sale of the undertaking, property and assets of the Swansea Company to the Traction Company.

Switzerland.—The Authorities of the Zurich Municipal Electric Tramways have just invited tenders for the supply of additional plant, including 24 motor tramcars, required in connection with the extension of the tramway system.

TELEGRAPH AND TELEPHONE NOTES.

A Bright Outlook.—We make the following extract from the *Outlook*, to which new periodical we offer our best wishes for a successful career:—"The commercial battles of the future will beyond a doubt be waged in the Pacific. England, the United States, Canada, Australia, Japan, Russia, and now Germany and France—in a word, all the great trading nations—are preparing for the struggle. What is England doing to meet the future? What, indeed! She has in the Canadian Pacific Railway an Imperial highway of the highest strategic and commercial importance; but that thread of empire Canada herself provided, without one cent of cost to the British taxpayer. Canada, too, has spanned the Pacific with mail and trade services to China and Japan on the one hand, and Australasia on the other, some of the Australasian colonies helping in the latter case. Is it too much to ask that England should follow up this spirited colonial lead by really doing something in the matter of the Pacific cable? Why allow it to be any longer the sport of committees and sub-committees in Downing Street? It is a great and pressing need in the interests of England, Canada and Australia alike, and in view of all that is happening in the Pacific, should be dallied over no further."

The Telephone Service.—The National Telephone Company has communicated with the Corporation, asking for a conference on the telephone question. This is in consequence of the City's decision to hold an inquiry. It is stated that the late Commission of Sewers many times invited the company to confer on the matter, but no notice was taken of the application.

The difference existing between the General Post Office and the Commission of Sewers, in respect of the laying of lines of underground telegraphs under certain City streets, came before the Railway and Canal Commission (Mr. Justice Wright, Sir F. Peel, and Viscount Cobham) on Thursday last week. The case was before the City of London Court in December (see ELECTRICAL REVIEW, December 3rd), when Mr. Commissioner Kerr decided the case in favour of the Post Office. The City Corporation appealed to the Railway Commissioners, contending that the order was not reasonable or just. After the speeches of counsel, Mr. Justice Wright said that the Corporation, in seeking to restrict the consent given to the Post Office, had no doubt been actuated by no captious or unfriendly spirit, but had striven to give effect to their view that when companies were making a profit by using public streets for private purposes, they should be compelled to give good value in return for concessions allowed to them. The question, however, arose as to whether they had the right of control which they claimed. Even if it were open to them to seek to impose such conditions as were in question in this case, the Court were of opinion that they were not reasonable, and would, according to the terms of the Act, "consent" that the streets should be opened by the Post Office authorised under the conditions usually imposed in such cases. Judgment was accordingly given for the Postmaster-General, without costs.

The Boston Town Council wishes the Post Office to bring its trunk lines to Boston, and also has in mind a scheme for a municipal local service.

In the House of Commons last week, Mr. Provand asked the Secretary to the Treasury what were the working expenses of the intertown telephones, and how much the intertown wires had earned since the date on which they were taken over from the National Telephone Company to December 31st, 1897. Mr. Hanbury replying, said that the capital expenditure—partly estimated—to December 31st, 1897, was £1,190,000. This sum includes the amount paid to the National Telephone Company. The gross earnings up to the same date amounted to £200,832. The working expenses, being included in those of the telegraph service, cannot be separately stated.

French Telegraph Extension.—The French Minister for the Colonies states that telegraphic communication is established between Senegal and Waguadougo, and will soon be extended to Fada-n-gourand.

German Telephones.—The German Imperial Post Office authorities have resolved to henceforth supply only single-receiver instruments for business or house telephone connections. A second receiver may, however, be obtained for 10s. from the post office authorities, who will maintain it for a certain sum. An annual payment of 5s. will be required from those subscribers already having double receivers, but the latter instruments will not again be issued for public use.

The Glasgow Telephone Inquiry.—The *Scotsman* learns that a demand is to be made on the Treasury for the production of Sheriff Jameson's report on the Glasgow telephone service. Mr. Hanbury will in the first place be privately approached, and, in the event of a refusal, the matter will be brought forward in the House.

Huddersfield Telephones.—The Postmaster-General has refused the application for a municipal telephone license, and the Council has dropped the proposal. A sub-committee is to consider terms of agreement with the National Telephone Company with regard to their application to lay wires underground.

Interruptions to Australian Land Lines.—In the formidable list which we published last week of interruptions of the trunk land lines of Australia, on which we rely for communication to the principal centres of that continent, we omitted to note that on December 9th last the West Australian land line, which joins a submarine cable to Java at Roebuck Bay was interrupted, and, as from the 8th till the 12th the South Australian land line, which runs from Adelaide in the south to Port Darwin in the north of Australia, was also broken down, it follows that Australia was completely isolated on December 9th, apart from the general delays on the 8th, 10th, 11th and 12th of that month, owing to the breakdown of the Port Darwin line. In addition to last week's list of interruptions, we have now to add that, on the 9th, current communication with Adelaide ceased, and, we learn from the *Times* of the 11th, that telegrams from Sydney were not received owing to the interruption of South Australian land lines. Since that date there has been a more or less spasmodic supply of telegrams from Australia conscientiously marked "delayed in transmission." Thus altogether, during the last five months, there have been at least 15 or 16 cases in which the trunk land lines in Australia have been broken down. In view of this, we can only admire the temerity with which the Eastern Telegraph Company proposes to land still another cable in West Australia, which of course will, just as much as the existing cables, have to depend on the very intermittent land line service under review for the transmission of telegrams to the principle centres of population on the south-east and east coasts of Australia. Although not affecting the land lines in that country, we learn from the Australian press that on December 1st last "the delay to the outward traffic from London is due to messages being diverted from the Indo-European line."

The Telegraph Wire Export Trade.—January has proved to be a very dull month as regards the exports of telegraph wire and apparatus connected therewith, from this country. In former years the January exports have usually fallen a long way short of those of the preceding month, but this year the decrease is much greater than usual, from £172,140 in December, 1897, to only £37,929 last month, the figures for January, 1897, being £62,120.

Telegraphic Addresses.—In the Commons the other day Mr. Hanbury, replying to Sir C. Cameron, said:—It is the fact that the rule of the Post Office that the first word in an abbreviated address must be a dictionary word containing not more that 10 letters, and that proper names and compound words—*i.e.*, words which appear in a dictionary joined by a hyphen—can only in rare cases be accepted, is intended, as the hon. member supposes, to preclude the registration of arbitrary words consisting of 10 letters, or constructed from the first and last syllable of a firm's name, or spelling the initials of the designation of a club, unless, indeed, these syllables or initials happen to make a real word.

CONTRACTS OPEN AND CLOSED.

OPEN.

Bilbao.—February 28th. The Secretary of State for Foreign Affairs has received a despatch from Her Majesty's Consul at Bilbao, reporting that the provisional board appointed in connection with the electric tramway which it is proposed to lay from Zumarraga to Zumaya, in the province of Guipuscoa, invite plans and tenders, to be received by February 28th, for the construction and equipment of the line. Further particulars of the conditions of the tenders for the above-named tram line and branch, which together measure 30 miles, may be inspected at the Commercial Department of the Foreign Office any day between the hours of 11 and 6.

Belfast.—March 8th. The Corporation wants tenders for the wiring of the new police cells, Chichester Street. Electrical engineer, Mr. V. A. H. McCowan. See our "Official Notices."

Berlin.—March 15th. The Municipal Traffic Deputation of the Town Council has opened a competition for the construction of several new electric tramways in that city. Exhaustive details concerning this project are contained in the *Elektrotechnische Zeitschrift* of the 13th inst., which mentions that proposals will be received by the Stadtische Verkehrsdeputation Rathhaus III, Berlin, by March 15th.

Bristol.—February 21st. The Electrical Committee wants tenders for 214 arc lamp posts. Electrical engineer, Mr. H. Faraday Proctor. See our "Official Notices" February 11th.

Canterbury.—February 23rd. Tenders are invited for the electric wiring and fittings for the Beaney Institute for the Town Council. Specifications, &c., to be obtained at the office of the City Surveyor, 28, St. Margaret's Street.

Carlisle.—February 25th. Tenders are being invited for the erection of the central station buildings in James Street. City engineer and surveyor, Mr. H. C. Marks, 36, Fisher Street.

Coventry.—March 8th. The Electric Light Committee wants tenders for the supply and erection of engine house, separate exciting and surface condensing plant, also pipework, switchboards and instruments for extensions of the municipal electricity works, Consulting engineer, Mr. Robert Hammond. See our "Official Notices" this week.

Denmark.—March 12th. Tenders are being invited for the supply of the engines, dynamos, accumulators, &c, required in connection with the new central station at Frederiksberg, near Copenhagen. Tenders to be sent to the Frederiksberg Sporveis-og Electricitets Aktieselskab, Gammel Kongerie, 140, Copenhagen V., from whom particulars may be obtained.

France.—March 31st. Tenders are being invited by the Municipal Authorities of Saint Chamond (Loire) for the concession for the lighting of the public streets of the town, either by gas or electricity. Particulars from, and tenders to be sent to, La Mairie de Saint Chamond (Loire).

Glasgow.—February 28th. The Corporation wants tenders for the hire or purchase of dynamos and engines, direct coupled or belt driven, capable of providing 1,100 break H.P. and spare power equal to 25 per cent. additional, also two rope driven dynamos to run at a speed not exceeding 500 revolutions per minute, and capable of providing 200 H.P. each at a potential of 230 H.P. The plant must be delivered by August 1st. Engineer, Mr. W. A. Chamen. See our "Official Notices."

Glasgow.—February 28th. The Corporation wants tenders for the supply of lead covered cables and accessories for twelve months, accumulators, motor transformers, motor driven boosters and switching apparatus. Mr. W. A. Chamen, engineer. See our "Official Notices."

Harrogate.—February 24th. The Corporation invites tenders for the supply and erection of vertical steam engine, dynamo, switchboard, motor, overhead conductors, &c., for sewage pumping plant. Mr. Geo. Wilkinson, borough electrical engineer. See our "Official Notices" February 11th.

Italy.—March 2nd. Tenders are being invited by the Municipal Authorities of Piacenza for the establishment of a central electricity generating station in the town for lighting and power purposes. Particulars may be had from, and tenders to be sent to, El Municipio di Piacenza, Italy.

Liverpool.—March 8th. The West Derby Board of Guardians wants tenders for supply and erection of boilers, engines, dynamos, batteries, wiring, &c., for the lighting of the Mill Road Infirmary. Consulting engineer, Mr. T. L. Miller. See our "Official Notices" for particulars.

Madrid.—February 22nd. The Secretary of State for Foreign Affairs has received a despatch from Her Majesty's Chargé d'Affaires at Madrid, enclosing copy of a Royal decree announcing that a public auction for the contract for repairing the national submarine telegraph cables during the next five years will be held at Madrid on February 22nd. Further particulars as to the cables in question may be inspected at the Commercial Department of the Foreign Office any time between the hours of 11 and 5.

Northwich.—March 5th. The Weaver Navigation Trustees are inviting tenders for the construction and erection of the necessary electric power plant for lighting and working the new swing bridges at Northwich. Current will be supplied by the Northwich Electric Supply Company. Engineer, Mr. J. A. Saner, M.I.E.E. See our "Official Notices" February 11th.

Pembroke (Ireland).—March 5th. The Lighting Committee wants tenders for the supply and erection of various plant, machinery, &c., for electric lighting. See our "Official Notices" this week for full particulars. Consulting engineer, Mr. Robert Hammond.

Plymouth.—February 21st. The Council wants tenders for the erection and completion of a refuse destructor with all necessary flues, fittings, boilers, &c. Borough engineer, Mr. James Paton, Municipal Offices.

Portsmouth.—February 22nd. The Corporation wants tenders for the supply and erection of Lancashire boilers, feed pumps, mechanical stokers, &c. Consulting engineers, Messrs. Kincaid, Waller & Manville. See our "Official Notices" February 11th.

Rochdale.—February 19th. The Corporation wants tenders for steam dynamos, balancer, and boosters, &c. Engineers, Messrs. Lacey, Clirehugh & Sillar. See our "Official Notices" January 14th.

Roumania.—March 15th. Tenders are being invited by the General Direction of the Roumanian Post and Telegraphs in Bucharest for the supply of 56,000 metres of galvanised iron and steel wire.

Shoreditch.—March 8th. The Vestry wants tenders for the supply of electric cables and sundries, also engineers' tools, ironmongery, &c. See our "Official Notices."

St. Helens.—February 21st. The Corporation wants tenders for various plant and machinery, &c., in connection with the proposed electric tramways. See our "Official Notices" January 28th for particulars. Consulting engineer, Dr. J. Hopkinson.

St. Pancras.—February 22nd. The Vestry wants tenders for dry back marine boilers with superheaters and brickwork seatings. See our "Official Notices" February 4th.

Sunderland.—February 25th. Tenders are invited by the Corporation for the supply of various cables, pipes, service boxes and stoneware casings for the year. Borough electrical engineer, Mr. J. F. C. Snell. See our "Official Notices."

The War Office.—April 27th. The Secretary of State for War is prepared to receive offers, competitive designs and specifications for the supply of portable electric search light apparatus. Particulars from the Director of Army Contracts, War Office, Pall Mall, S.W. See our "Official Notices" February 4th.

Victoria.—March 21st. The Telegraph Department of the Victorian Government Railways is inviting tenders for the supply of alternating current transformers and one main switchboard. Tenders to the Telegraph Superintendent's Office, Spencer Street, Melbourne.

Wallasey.—March 17th. The District Council wants tenders for the supply of engine, alternator, exciter, two Lancashire and one water-tube boilers, and condensing apparatus. Engineer, Mr. J. H. Crowther. See "Official Notices" February 11th.

Watford.—March 16th. The District Council wants tenders for the supply and erection of various plant for the electric lighting of the district. For details of the seven sections see our "Official Notices" February 11th. Mr. W. C. C. Hawtayne, consulting engineer.

West Ham.—March 8th. The Council invites tenders for wiring and fitting up various buildings, including the Town Hall, police court, Corporation stables, fire stables, &c. Mr. J. Steinitz, borough electrical engineer. See our "Official Notices" this week.

CLOSED.

Aberdeen.—The contract for the supply of a 650-H.P. engine and dynamo (£4,147) is being given to Messrs. Mather and Platt, Limited, £60 extra being paid for adapting it for traction work

Belfast.—The Harbour Commissioners have accepted the following tenders for the supply of electrical plant for the extension of the electric lighting of the quays at the Harbour:—

Dynamos (two)	Mr. Wilson Hartnell
Switchboard and switches	Williamson & Joseph
Arc lamps	Mr. C. A. Müller
Lamp posts	Mr. T. Scott Anderson
Mains, boxes, &c.	British Insulated Wire Company

Bootle.—The Town Council has accepted the following tenders:—

Contract No. 1.—Boilers and economisers	T. Parker, Limited, at £11,791, less £650 allowance for present engines, dynamos & switchboards.
„ „ 2.—Engines, dynamos, &c.	
„ „ 4.—Feeders, mains, service lines, &c., and maintaining same for 10 years	£10,096.

„ „ 5.—Messrs. T. Parker, Limited, for the running of electricity supply works and supply of current for public and private purposes as follows:—For each 10 ampere arc lamp run from one hour after sunset to one hour before sunrise (3,620 hours per annum), £24 per annum; for each 10 ampere arc lamp run from one hour after sunset to midnight (1,810 hours per annum), £12 per annum; for each lamp hour added or deducted from above, 1·55d.; for each incandescent lamp used for public lighting, 3d. per unit; for remainder of current up to guarantee of 100,000 units per annum for public and private purposes, 3·75d. per unit; for first 25,000 units above guarantee, 1·75d. per unit; for second 25,000 units above guarantee, 1·25d. per unit; for every unit in excess of 150,000 units, 1d. per unit.

The question was raised by some Councillors as to why the tender of a local firm had not been accepted. Councillor Hall replied that the acceptance of the local tender would have meant a loss to the ratepayers of £4,700 in three years.

Bradford.—The City Council has accepted tenders as follows for electric lighting plant:—

Two dynamos.—Siemens Bros. & Co., Limited	£2,800
(Extra armature)	600
Two 600-H.P. steam engines.—Willans & Robinson	4,590

A sub-committee is to inspect combined lighting and traction central stations on the Continent.

Burnley.—The Corporation has accepted the tender of Messrs. G. E. Bellis & Co., for two combined engines and dynamos for electric lighting extensions at £4,888.

St. Pancras.—The Vestry has accepted the tender of the Fowler-Waring Cables Company (£4,196 odd) for cables, &c., for the extension to Queen's Crescent, Malden Road and Prince of Wales Road.

Wimbledon.—The following tenders have been accepted in connection with the Council's electric lighting scheme (Mr. A. H. Preece, consulting engineer):—Buildings, Burgess £3,388. Boilers, Babcock & Wilcox £2,482. Steam engine and dynamo, Crompton and Co. £4,181. Mains, W. T. Henley's Co. £15,792. The switchboard, condenser, and crane contracts have not been finally decided yet.

FORTHCOMING EVENTS.

1898.

Friday, February 18th, at 6.30 p.m.—Institution of Electrical Engineers. Students' visit to the generating stations of the St. Pancras Vestry.

Finsbury Technical College Conversazione. Lecture on "Wireless Telegraphy," by Dr. S. Thompson.

At 7.30 p.m. Staff smoking concert of the City of London, the Metropolitan, and the London Electric Lighting Companies, at the Crown Room, Freemason's Tavern, Great Queen Street, Holborn, W.C. Chairman, Mr. P. W. D'Alton.

Saturday, February 19th.—Latest date for the Rochdale Corporation electric lighting tenders.

Monday, February 21st.—Latest date for Bristol Corporation arc lamp posts tenders.

Latest date for the St. Helen's Corporation electric tramway plant tenders.

Whitehall Rooms of the Hôtel Métropole. Webb Testimonial presentation reception at 9.30 p.m. Presentation at 10 o'clock p.m.

Tuesday, February 22nd.—The Federated Institution of Mining Engineers, 26th general meeting at Newcastle-upon-Tyne. Various papers are to be read, and among those to be open for discussion are the following:—"Light Railways," by Mr. Leslie S. Robinson. "A One-rail or Trestle System of Light Railway," by Mr. Fred. J. Rowan. "On Some Dangers attending the Use of Steam Pipes," by Mr. A. L. Steavenson. "Machine Coal-mining in Iowa, U.S.A.," by Mr. H. Foster Cain. "Latest Developments and the Practical Application of Alternating Multiphase Machinery for Power Transmission," by Mr. Walter Dixon. Visits will be paid to the Telegraph and Telephone Departments at the General Post Office, Mr. A. W. Heaviside, Superintending Engineer.

Latest date for St. Pancras tenders.

At 8 p.m.—Institution of Civil Engineers.—Papers to be read with a view to discussion: (1) "The Theory, Design and Working of Alternate Current Motors," by Mr. Ll. B. Atkinson, Assoc.M.Inst.C.E.; and (2) "The Dublin Electric Tramway," by Mr. H. F. Parshall, M.Inst.C.E.

Latest date for the Portsmouth electricity supply plant tenders.

Wednesday, February 23rd.—Second day of the Federated Institution of Mining Engineers. Various excursions, including visit to the works of Ernest Scott & Mountain, Limited, Newcastle-on-Tyne.

Latest date for the Canterbury Council wiring tenders.

Thursday, February 24th.—Latest date for tenders for Harrogate Corporation electrical plant for sewage pumping.

At 8 p.m.—The Institution of Electrical Engineers. "On the Manufacture of Lamps and other Apparatus for 200 volts Circuits," by G. Binswanger-Byng.

Friday, February 25th, at 6.30 p.m.—The Institution of Electrical Engineers. Students' visit to the Shoreditch electricity supply station. Applications at once to the Students' Hon. Sec. (Mr. S. Grant, 28, St. Mary Abbot's Terrace, W.) as the number will be limited to 20.

At 8 p.m.—The Institution of Civil Engineers.—Students meeting. "The Problem of Train Resistance," by C. E. Wolff, B.Sc., Stud.Inst.C.E.

Saturday, February 26th, at 4 p.m.—Physical Society in the Chemistry Lecture Room, Keate's Lane, Eton College. The Rev. T. C. Porter will describe:—1. A new theory of geysers. 2. A new method of viewing Newton's Rings. 3. Experiments bearing on the sensation of light. 4. A method of viewing lantern projections in stereoscopic relief. 5. Winter observations on the shadow of El Teide, with a new method for measuring approximately the diameter of the earth. 6. Temperature of the water of Niagara.

NOTES.

Correspondence.—We have received, just as we go to press, a letter from Mr. Robert Hammond, regarding the Shoreditch dust destructor, replying to the letters of Messrs. Kershaw and Russell, which appeared last week. We regret being compelled to defer publication until our next issue.

Postal Telegraph Factory Staff Dinner.—The staff of the Postal Telegraph Factory, Mount Pleasant, held their fourth annual dinner at the Inns of Court Hotel on Saturday, February 5th, Mr. Martin F. Roberts, the superintendent of the factory, presiding. Among the guests present were Mr. J. C. Lamb, C.B., C.M.G.; Mr. J. Ardron; Mr. H. C. Fischer, C.M.G.; Lieut.-Colonel P. G. von Donop, R.E.; Prof. W. H. H. Hudson, Dr. Mumford, Dr. Walmesley, Messrs. J. W. Eames, W. Slingo, W. V. Morten, and G. W. Hook. The occasion was the 28th anniversary of the acquisition of the telegraphs by the State, and in responding to the toast of "The Chief Office" (proposed by the chairman), Mr. Lamb dwelt upon the progress made in telegraph engineering, and in the general efficiency of the service to the public during the past 28 years. A hope was also expressed that, as many present had assisted at the transfer of the telegraphs in 1870, so, also, many would live to see complete success attending the efforts now being made to render the telephone service equally efficient. In proposing the toast of "Electrical Engineering," Mr. A. Brooker emphasised the importance of the pioneer work done by telegraph engineers, which rendered possible the rapid progress in other more modern branches of electrical engineering, and mentioned that the running of two properly designed alternators in parallel might be more exciting, but was certainly a far less difficult task than the running of two multiplex motors and distributors for eight hours synchronously. In the absence of Mr. W. H. Preece, Mr. J. Ardron responded. Mr. J. M. G. Trezise proposed "The Guests," and referred to the long and remarkable career of Mr. H. C. Fischer, and to the acknowledged efficiency of the Royal Engineers, especially the Telegraph Battalion—a point upon which those present were well qualified to express an opinion. Mr. Fischer and Lieut.-Col. von Donop replied in felicitous terms, the latter acknowledging the advantages resulting from the close connection between the Engineers and the Postal Telegraphs. A varied vocal and instrumental musical entertainment was given during the evening by members of the staff.

Institution of Mechanical Engineers.—The 51st annual meeting of this Institution was held in the hall of the Institution of Civil Engineers, Great George Street, Westminster, on Thursday and Friday last week. The chair was occupied during the earlier portion of the proceedings by Mr. E. W. Richards, the retiring president, who introduced Mr. Edgar Worthington, the newly-elected secretary, to the meeting. The report stated that at the end of last year the number of names on the roll was 2,496, as compared with 2,359 at the end of the previous year. During 1897 227 names were added, the loss by death being 30, and by resignation or removal 60. The result of the ballot for the election of the council was announced, Mr. S. W. Johnson being elected president, and Mr. Arthur Keene and Sir William White vice-presidents. The discussion was afterwards resumed upon a paper read at the last meeting by Mr. Philip Dawson on "Mechanical Features of Electric Traction."

(*Continued on page* 227.)

THE MAKING OF CHLORIDE ACCUMULATORS.

(*Concluded from page* 188.)

The description of the manufacture of the chloride negative plate may be fittingly concluded by illustrating a complete cell showing plates, and this is given in fig. 6.

Comparatively speaking, the manufacture of the positive plate is a simple operation. Contrary to what occurs in making the negative plate, the positive grids are made first. They are cast in moulds by means of compressed air, as is done in the case of the negative plates. The material is antimonial lead, and the moulds are arranged to leave a series of holes in the frames, and into these apertures are pressed cores of lead. The core takes the form of a pure lead rosette, and the process of making this rosette is exceedingly interesting. First of all, long strips of pure lead, about ½ inch in width, are passed through specially designed machines, which will rib and automatically cut it into short lengths. Fig. 7 gives a fair idea of this operation which is known as gimping; the gimped pieces are then collected and carried to adjoining tables, where the lengths are spun by boys into small rosettes (fig. 8). The rosettes are then pressed by hand into position in the plates, the process being indicated in fig. 9. When the plates are filled they are passed through a hydraulic press, which completes the keying of the rosette mechanically, the plate being then practically ready for forming. The formation is effected by coupling up the plates with a set of dummy negatives and passing the current continuously through the cells, the rosettes becoming finally coated with a fine adherent hard crystalline coating of peroxide.

After the formation process the plates are then cast up into sets in a similar manner to the negative. That practically completes the general outline of the manufacture of chloride plates. There are, of course, many details that could not very well find a place in this article, but probably sufficient has been said to indicate the general nature of the process.

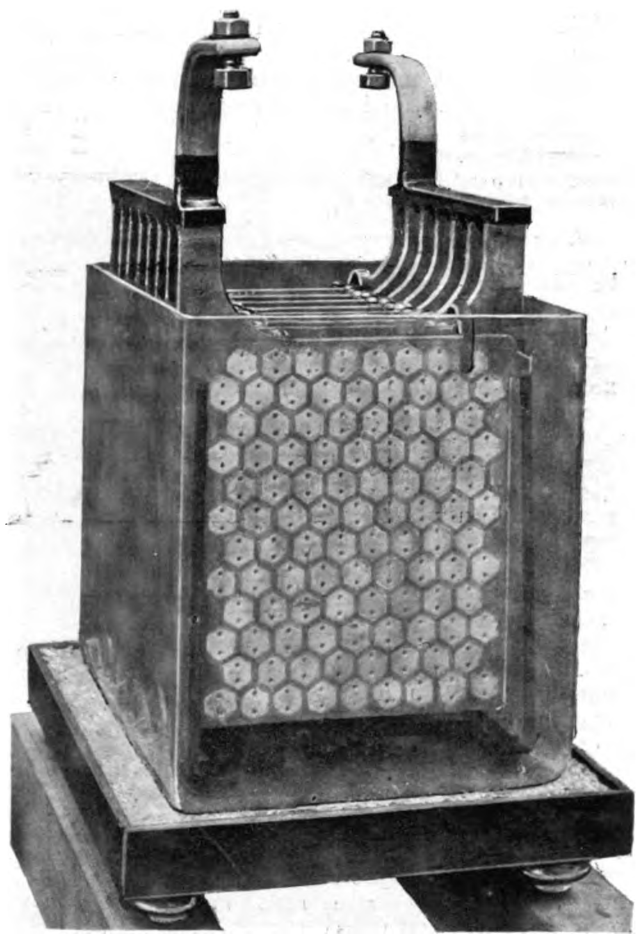

Fig. 6.—Complete Cell Showing Negative Plate.

Fig. 8.—Making the Rosettes.

There are many other things at these accumulator works that one ought to refer to. There is the electrical plant, which, in a way, is interesting, and consists of two 90-H.P. compound condensing engines, each directly coupled to a Mather & Platt multipolar dynamo; then there is a high-speed compound engine, coupled direct to a two-pole dynamo, also of Mather and Platt manufacture. In addition is a motor generator, which is capable of delivering current at 10 volts. The steam raising plant consists at present of two Lancashire boilers, though arrangements are being made for extending it. The generating plant is utilised not only for formation purposes, but serves to light the extensive works and to furnish energy for driving motors, which form quite a distinguishing feature of the place. There is nothing specially interesting about the switchboard. Each unit has a separate panel, and there are separate boards for controlling the energy used in the formation baths and in the lighting and motors. Housed in the same building as the generating plant is a large double-throw pump, which is used for the condensers, a double set of pumps for supplying the hydraulic accumulator, and also two Westinghouse compressors for the supply of compressed air.

There are, of course, the usual workshops necessary in such establishments. There is a large joiners' shop, equipped with modern machinery, and driven by electrical means. There is also a mechanics' shop, fitted with machine tools, and close by are the stores. It is very important that the workmen employed on certain sections of accumulator work should be kept moderately clean, and though we suppose it is not an easy matter to make a man clean by Act of Parliament, little trouble is experienced in this direction at the Chloride Works; moreover, the management insist that every man before he commences or recommences work shall have a substantial meal, and the enforcement of this rule has resulted in a general improvement in the health of the employés.

The testing of accumulators forms a very important part of the work carried on, and a large room is set apart for commercial tests of every description. Moreover, not only is the chloride cell elaborately tested, but all known types of cell are very carefully scrutinised and compared with the home article. With the exception, as we have pointed out before, of purchasing raw materials and the glass boxes, every operation necessary to produce a chloride cell is carried out on these works; there is little doubt that for completeness, for facility and convenience of manufacture, the Chloride Works rank among the best in the country.

Fig. 7.—The Gimping of the Lead Strip.

Some allusion has been made to the directions in which the chloride cell is performing useful work; but perhaps the most interesting of its many applications is the use that is being made of the cell for traction work, both in conjunction with the overhead wire system, and in cases where the accumulator is carried on the car. As an auxiliary to the overhead system, the excellent service of the Chloride cell is not confined to this country. One of the most notable examples is the system of the Union Traction Company, of Philadelphia, which operates some 500 miles of road. In making recent extensions on this line, it was found that it would be necessary either to build a new power house, or instal a battery sub-station, as the required addition to the existing feeder system would necessitate such an enormous outlay for copper, as to render it commercially impossible. It was found that the cost of copper alone to carry out this extension, and double the service on the section, would be four or five times the total cost of a battery installation to fully meet all the requirements, and that a new power house was out of the question, on account of the heavy operating expenses. Before the extension was made, the pressure at the end of the feeder was barely enough to operate cars on schedule time, and the pressure varied as much as 50 per cent.

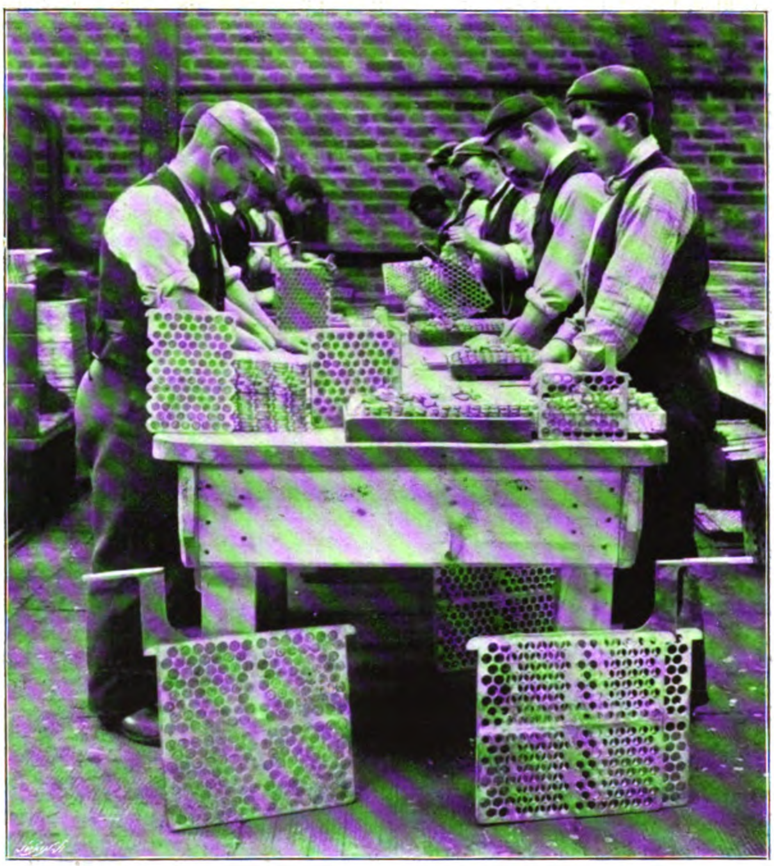

Fig. 9.—Pressing the Rosettes into the Positive Grids.

The load on the section varies from 100 to 700 amperes; the feeder carries a constant load of 400 amperes, the battery discharging or charging to the extent necessary to maintain this condition. The result in actual practice is found to be that the feeder load remains constant at this average current, and is absolutely independent of the fluctuating demand on the line. It is claimed that the battery in these cases enables the generators always to run at full load, and consequently at the highest point of efficiency, and to act as a cushion to the engine in the event of the circuit breaker opening when trouble occurs on the line.

On the Woonsocket line they have been able to show in pounds, shillings and pence what the value of a battery is, and it has been found that the saving in operating expenses amounts to £700 per annum.

In this country it has been already demonstrated on the existing electric tramway systems that one of the most valuable functions of a storage battery is to provide a reserve in case of breakdown.

In accumulator car systems, the Chloride cell has established a good reputation; and is being used on four lines in Paris at the present moment. The working results of one of these systems was published in the Review some months ago. Even on the much maligned Central Tramway system, where these cells have now been used for three years, the record is a good deal better than is generally supposed; indeed, we are not exaggerating when we say that the cost of upkeep of the batteries does not exceed 1⅜d. per car mile.

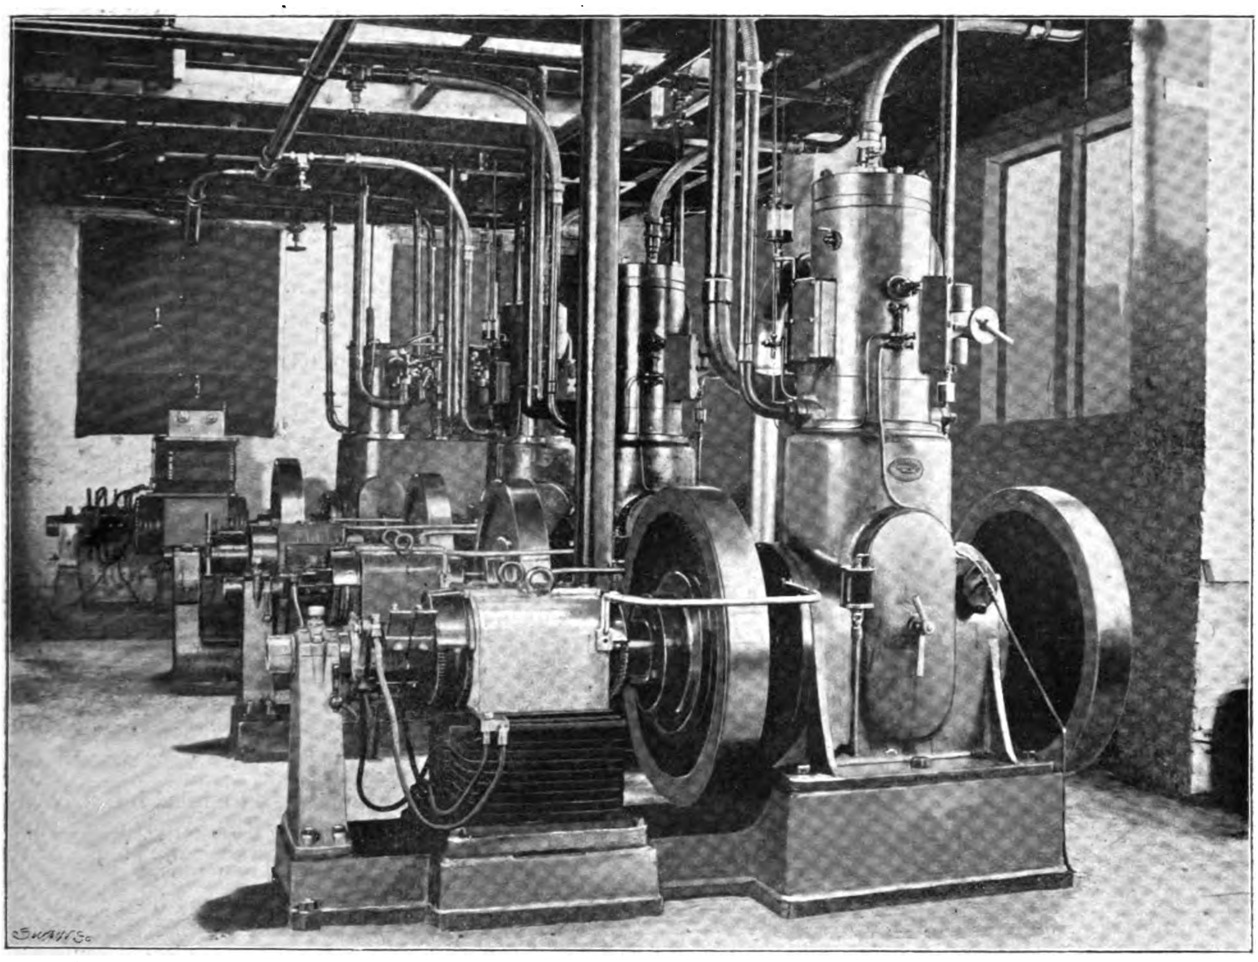
The Americans were always fond of big things, but it was generally supposed in this country that, in the use of storage batteries for lighting, we should not have had to yield the palm to our American friends; yet the Chicago Edison Company are about to put down what is very properly termed the largest storage battery in the world, one that is costing £20,000.

GAS ENGINES FOR ELECTRIC LIGHTING.

It is generally admitted that the internal combustion engine will play a conspicuous part in the cheapening of electricity, but one must be forgiven if at times one thinks the progress made in gas engine construction seems to be a little slow. At the same time, there is abundant evidence that gas engines for electric lighting work have been materially improved during the past few years. They are not only giving less cyclical variation, but the economy of a modern gas engine shows a most marked advance on the performances of, say, four years ago. Compared with steam motors, the size of the gas engine is still insignificant, and the weight of material per effective horse-power is very considerable; but the one great drawback that was urged against gas engines for electrical work, namely, unsteady running, may be said to have completely disappeared.

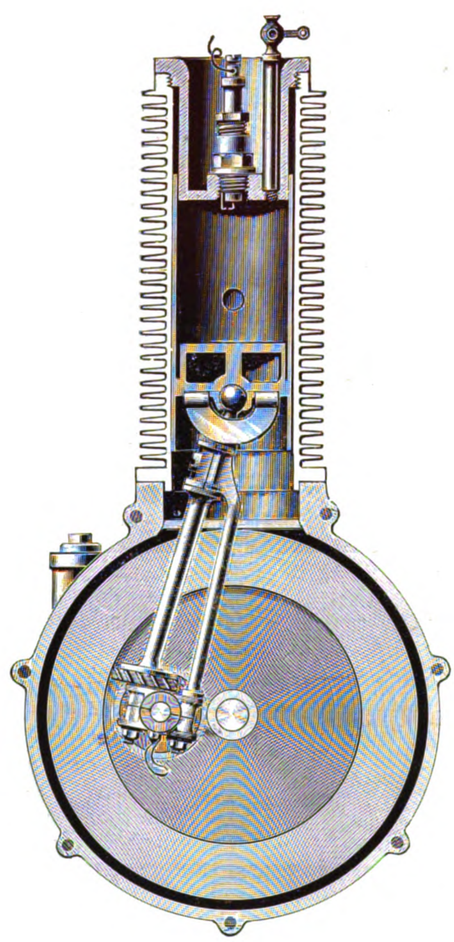
In the use of gas engines for central electricity works, much interest has been recently created by the success that has attended the running of such motors at Leyton, and no doubt we may see an immediate extension of gas engine stations.

It may be a matter of interest to many of our readers to learn that for some two years there has existed at Clapham Road a central station which has attained a distinct measure of success in lighting portions of the surrounding district. The plant comprises gas engines direct-coupled to dynamos, and they vary in size from 17 B.H.P. engines down to 2½ B.H.P. The combined plant is capable of giving 1,000 amperes at 110 volts, the average nightly load being 600 amperes. The works, which are quite of moderate size, were originally started in a small dwelling house, and it may be mentioned here that the lighting plant really forms part of a business that was started by Messrs. Paris Singer & Co., to manufacture the Dawson gas engine. The lighting of a few surrounding shops and houses was attended with so much success, that extensions speedily became necessary, and to meet the ever increasing demand, a small central station was eventually erected. A view is given of the plant erected in this building, though engines of similar capacity are still working in other parts of the works. The most notable feature is that the dynamos are direct-coupled to the engines, and to give an instance as to the smallness of the floor space occupied, three sets of 11 units each only take up a space of 13 feet by 8 feet, and this leaves ample room between the machines. The sets at present in use comprise one 35-B.H.P. double cylinder engine, six sets of 11 units, three of 4 units, and two of 2½ units capacity. There are two batteries of accumulators of the E.P.S. K 66 type, which are run in parallel with the machines at the time of heavy load, and thus become effective in the event of an ignition tube breaking. The battery also takes charge of the night load, and meets the whole of the Sunday demand, the engines being shut down from Saturday night till Monday morning. Water for circulating in the cylinder jackets is pumped from a well adjoining the works to tanks placed above the engine room; after passing round the cylinders the water passes to other tanks, and from thence runs back to the well. Town gas is at present employed for the engines, but we understand that when the load increases, producer gas will be made on the premises, plant for this purpose having been already erected by Messrs. Paisley.



A Gas Engine Station.

Undoubtedly the most interesting feature of the plant is the type of engine, which is extremely simple. It is designated the rotary piston type, and is practically valveless. The cycle adopted is the Otto, and some ideas of the interior mechanism may be obtained from the detailed drawing annexed. It should be explained, however, that this illustration is of the smaller class of engine made by Messrs. Paris Singer & Co., and is designed for motor cars. The action of the engine is practically as follows:—In every two complete revolutions of the engine, the piston is rotated completely round. As the piston is hollow, the work done by the explosive mixture is performed inside the piston. To provide for the admission of the gas, there are two holes in the piston opposite each other, and in the process of rotation, these holes become uncovered at the ports, and thus admit the mixture. During the period occupied by compressing and firing, the piston has been rotated, and at another position of the cylinder the holes become uncovered at the exhaust outlets, and the products of combustion pass out. The two holes in the piston, therefore, serve as a means of taking in the explosive mixture, and of getting rid of the



burnt gases. The rotating action of the piston is obtained in the following manner. For all intents and purposes the connecting rod may be considered as split in two, one portion of which is rigid, and the other portion is free to revolve. A tangent wheel on the front rod is driven by a quick pitch wheel fixed near the end of the crank pin; the piston rod is connected to the piston by means of a universal joint. The explanatory drawing will probably make the action of the mechanism clear.

It would seem as if there might be some gain in permitting the explosion to take place inside the piston, rather than in the cylinder; the cylinder walls are not thereby directly affected by the heated gases, neither is the lubrication of the piston interfered with.

The ordinary ignition tube is employed, the position being altered in the different sizes. A form of inertia governor is used, the regulation of the engine being effected by the hit-and-miss principle.

Probably we shall be able to say something eventually on the cost of producing electric energy at these small works. Our thanks are due to Mr. R. M. Campbell, the works manager to Messrs. Paris Singer & Co., for showing us round the works and explaining the very interesting features of the gas engine, which are now being made in considerable numbers.

ELECTRIC CRANES.

This somewhat well-worn subject has been brought before the Northern Society of Electrical Engineers, Manchester, by Mr. J. G. Statter.

The chief point of interest centres in the description of an electric crane made by the author's firm, which, for some special purposes, seems to have considerable advantages. It is a three-motor crane, in which the motors are connected in series order, and worked by constant current with variable pressure.

The motor brushes are made to rock through nearly half a circle by means of a chain and wheel, and the motors are started, stopped and reversed, simply by moving their brushes. When the brushes are on a diameter at right angles to the pole gaps there is no torque, no counter E.M.F., and no motion; but, moving the brushes to one side or the other causes a torque one way or the other and motion accordingly, so that the commutator and brushes act as their own switches, for stopping, starting, and reversing.

Such a system requires a constant current dynamo, specially designed for the crane, or a motor generator for constant current. The pressure rises and falls in accordance with the load on the motors.

The paper also describes a fanciful method of working a crane by a motor, in which the armature and field magnets both revolve; but as it is admittedly only a toy and of low efficiency, not being completely under control, it is of no interest to describe it here.

The rest of the paper deals with well-known apparatus, three-motor and single-motor cranes, without adding much to the knowledge of these already well-known and common types.

So far as we can gather, the single-motor crane finds most favour with crane makers, as it is the only system which can be readily adapted to existing cranes and to standard designs of mechanically-driven cranes. In fact, many square shaft-driven cranes have been converted, at small cost, and with little alteration, into electric cranes with a single motor. The three-motor system requires a specially constructed crane, and the series system of working with constant current requires not only a specially-made crane, but also a special generator. These, in practice, are serious drawbacks to the two latter systems.

A single motor with an open and crossed belt drive finds much favour with some crane makers, simply on account of its simplicity and effectiveness, and the same simple method is finding considerable favour in applying electro-motors to lifts, as manipulating the lift by belts has been found to be more economical and reliable than working them by purely electrical control, through a most complicated box of cam shafts, bevel wheels, clutches, and switches, all of which require continued attention. Any good motor can be used for crane driving, the details, switches, resistances, and gearing of the motor to its work are the only points in which electrical engineering problems arise.

Royal Institution.—On Friday, the 11th inst., a lecture was delivered at the Royal Institution by Dr. J. H. Gladstone, on the "Metals used by the Great Nations of Antiquity," in which he traced the growth of the metal working arts from the earliest periods of history. In connection with the occasion, a conversazione took place at the Royal Institution the same evening, which was well attended. At this a number of interesting samples of alloys and rare metals was on view, including aluminium from the British Aluminium Company, the well-known Atlas anti-friction metal, Delta metal, and rare metals from the firm of Messrs. Johnson, Matthey & Co., including a specimen of uranium, valued at £7,000.

NOTES.

(*Continued from page* 222.)

Obituary.—Our American exchanges record the death of Mr. O. B. Shallenberger, which occurred on January 24th, at the early age of 38. In 1884 he resigned from the U. S. Naval service, and devoted, from that time forth, his whole attention to electrical science. In the same year he joined the electric light department of the Union Switch and Signal Company of Pittsburg, and in 1885 he took charge of the setting up and operation of the Gaulard & Gibbs apparatus imported from Europe by Mr. Westinghouse. At this time his practical acquaintance with alternating currents began. After Stanley's experiments at Great Barrington, Mass., and other experiments conducted at Pittsburg by Mr. Shallenberger, the alternating current system was adopted, the Westinghouse Company was organised and Mr. Shallenberger was appointed chief electrician. Mr. Shallenberger was one of the earliest to apply the theories then known about alternating currents to practical operation. A contemporary remarks that he was the first in America to succeed in coupling alternating current generators in multiple. The system used for incandescent street lamps in series, with a shunt of high self-induction around each lamp, was one of his early inventions. Probably his most beautiful conceptions are exhibited in his electric measuring instruments. Mr. Shallenberger was consulting engineer for the Westinghouse Electric and Manufacturing Company, and also organiser and president of the Colorado Electric Power Company.

We regret to hear of the death of Mr. J. B. Chapman, acting principal technical officer of the Engineer-in-Chief's Office, General Post Office. Mr. Chapman, who was an old and valued servant of the department, was well known in connection with high-speed automatic working, many improvements which have been made in this system having been largely due to his initiation.

Lectures.—On the 7th inst., Dr. O. Lodge lectured at Leicester, under the auspices of the Literary and Philosophical Society, on "Electric Oscillations." Dr. Lodge said that much remained to be done before the "wireless telegraph" system could be made of practical utility. It was possible to telegraph through obstacles, but these offered more or less resistance. A message had been sent a distance of 9 miles in Germany and 15 miles in England by means of this system, and at present it was unknown up to what distance it was of use.

Mr. T. B. Murray, Glasgow, on Monday last week, lectured to the members of the East of Scotland Engineering Association on "Electric Motor Carriages." The lecturer, in his opening remarks, stated that to Edinburgh belonged the distinction of having produced the first electric carriage, which was built by a Mr. Davidson about the year 1842. Mr. Murray explained the advantages of the Johnston-Murray patent motor for this class of work. At the conclusion of his paper the lecturer showed a series of lime-light views, depicting a few historical vehicles and the latest types of American, French, and English electrical road carriages.

On the 7th inst., at the Royal College of Science, Dublin, Mr. W. Brown, B.Sc., commenced a series of 15 lectures on "The Practical Application of Electricity."

Prof. Wertheimer lectured at the Merchant Venturers' Technical College on "Wireless Telegraphy" on 5th inst., and will repeat the lecture and experiments on March 2nd.

At a meeting of the Manchester Geological Society on 8th inst., Mr. Bigg-Wither read a paper on "Electrical Shot-firing in Mines."

Prof. John Milne, F.R.S., delivered a lecture at the London Institution, Finsbury Circus, a few days ago, on "Geological Changes Beneath the Ocean."

Prof. S. P. Thompson, president of the Wolverhampton Literary and Scientific Society, will deliver his presidential address at the Agricultural Hall, on February 24th, his subject being "The Coming of the Electric Horse." He will be afterwards entertained at a supper at the Star and Garter Hotel, to which the mayor and the local members of Parliament have been invited.

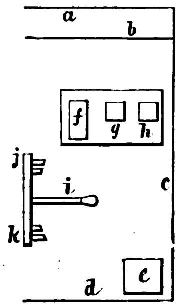
The Telephone and the Electric Tramway Wires in South Staffordshire.—On Wednesday, at the Walsall County Court, before his Honour Judge Griffith, the National Telephone Company, Oxford Street, London, were sued by Messrs. Bedworth & Son, merchants, of 10, Mill Street, Great Bridge, for £37 4s., the price of a horse, the death of which was caused by one of the company's telephone wires giving it a fatal shock. Mr. Ensor appeared for the company, and claimed that the South Staffordshire Tramway Company should be joined with them as defendants, as they were jointly liable. Mr. Disturnal appeared for the tramway company, and Mr. Parfitt represented the plaintiffs. The case was not gone into, but the facts were stated to be that a man in the employ of the telephone company was engaged in repairing one of the wires, and that while so engaged the wire fell across another wire, the latter belonging to the tramway company. This sent through it a current which made the man drop the wire, and after it had fallen plaintiffs' horse became entangled in it, and was fatally shocked. Mr. Ensor urged that the tramway company were bound to insulate their wires, and as they had failed to do this, they were really responsible for the accident. Mr. Disturnal submitted that to make a third party liable in such a case, liability to indemnify must be shown. His Honour held that the falling of the telephone wire on the tramway wire was a trespass, and that the tramway company could not be held liable for that. He therefore dismissed the action against that company with costs. Mr. Parfitt said that, after Mr. Ensor's argument, there could be no defence against plaintiffs' claim, as the parties had agreed that the damages were £35 4s. 6d. He asked his Honour for judgment for that sum. Mr. Ensor said his only defence was, that it was the electricity passing from the tramway wire to the telephone wire which had caused the man to drop it, and it was in that wire that the horse was entangled. He submitted to his Honour that if he were holding a cannon ball, and someone struck his arm and caused him to drop the ball on another person's toes, the man who struck the blow would be liable. This was a similar case. His Honour declined to give judgment on hypothetical cases, but said the telephone company had no right to let their wire rest on the tramway company's wire. Mr. Ensor said that, under the circumstances, he must submit to judgment, which was therefore given for £35 4s. 6d. and costs.

Presentations to Mr. H. C. Fischer.—Mr. H. C. Fischer, C.M.G., who retires from the Post Office service at the end of the month, took formal leave of the officials on Thursday last week, at St. Martin's-le-Grand. Among the presentations from the various departments were the following:—Silver candelabra from Mr. Fischer's personal staff and the controlling and supervising officers (male and female), past and present, of the Central Telegraph Office; three silver fruit dishes, with inscription and monograms, from personal friends in other branches of the Post Office; a brown leather Gladstone dressing bag, containing silver-stoppered cut-glass bottles and silver-mounted fittings; a silver cigar box (cedar wood lined) bearing an engraved centre piece representing a cable with ends showing, presented by the officers of the late Submarine Telegraph Company who were transferred to the service of the Post Office in 1889; a smoker's cabinet, of polished coromandel wood, with silver fittings, from members of the male staff of the Central Telegraph Office; and a silver vesta box, bearing initials H. C. F. and date, from Mr. Fischer's head messenger and his assistant. Mrs. Fischer was presented with a handsome diamond ruby and pearl bracelet.

The Institution of Civil Engineers.—On Tuesday next papers will be read on "The Theory, Design, and Practical Working of Alternate-Current Motors," by Llewelyn B. Atkinson, Assoc.M.Inst.C.E., and "Dublin Electric Tramways," by H. F. Parshall, M.Inst.C.E.

The Ferraris Memorial.—The German fund in aid of the proposed memorial to the late Galileo Ferraris amounts to £190. Of this sum, Dr. Kittler has collected £68, whilst the remainder comprises contributions obtained through the efforts of the editors of the *Elektrotechnische Zeitschrift.*

Ingenious "Booster" Connections.—Mr. James F. Austin, of Philadelphia, writing to the *Street Railway Journal*, says:—"Making the most of things," is the street railway man's watchword now-a-days, and the man who really can make the most of things generally comes out pretty near the top. In a power house not long since, I found a very ingenious arrangement of the generators, whereby one, or three, might be used as the very fluctuating travel demands. In the drawing, the line is shown, the several divisions being designated as follows: *a* and *b*, branches; *c*, main line, and *d* an extension of the main line three miles long and beginning about five miles from the main power station in which were three units; *f*, a modern direct connected generator running at 90 revolutions per minute, and having an output of 1,300 or 1,400 amperes. The smaller generators, *g* and *h*, were of the type of five or six years ago. At *e*, another station was located which could start one of the older generators at will. This company operates about 160 cars, and has a seaside resort at the end,



d, and travel varies from a full load for all the units, to a small load for generator, *g*. In the main power station, connections are such that the three generators can all be operated in multiple, or as travel demands, the line, *b*, can be put on unit, *g*, and the main line and branch, *a*, operate from *f* and *e*. By another combination, the generator, *h*, can be connected up as a "booster," and the main line, clear to and including *d*, may be operated from unit, *f*, and the booster, *h*, without the use of the generator at *e*. The connection of the generator, *h*, is through the switch, *i* (shown in detail), and when the lever, *i*, is thrown in contact with *j*, the generator is running in multiple with the others, but when the lever is thrown to *k*, the connections are such that the machine becomes a "booster," and works in that capacity with whatever feeders may be connected with it. The switch connections are such that either of the branches can be "boosted" or isolated to a single generator at will.

Petroleum Fuel.—The *Scientific American* remarks that it is gratifying to learn that the experiments which the Bureau of Steam Engineering is carrying out in the Stiletto in the use of liquid fuel are meeting with complete success. The great advantages of liquid fuel are, that it may be run into the bunkers or tanks by gravity, thus doing away with the tedious and costly loading by hand. It can be brought into the furnaces without handling, thus reducing the number of stokers, and it produces no ashes. A ton of oil, moreover, contains about twice as much heating power as a ton of coal, and hence the amount of fuel supply may be doubled without adding to the weight of the vessel. With a combination of liquid fuel and the turbine in the same vessel, we may look for some great developments in the present Government experiments.

Informations!—The following note from a correspondent speaks for itself:—"Kindly favour me in asking some one of our numerous readers to give us a few practical hints on the drum bar wound armatures, evolute end windings, the best means in conecting up the joints. You will extreemly oblige C. W."

Heat and Mechanical Work.—The highly interesting article by Marcel Deprez, which appears on page 239, was communicated by the author to the *Revue Générale des Sciences*.

Behr's Lightning Express.—Mr. F. B. Behr informs the *Times* that the Belgian Government has named a commission composed of the following engineers in the service of the State railways:—M. E. Gerard, engineer-in-chief and Chef du Cabinet of the Minister of Railways (president), M. A. Degraux and M. Flamasche, engineers-in-chief of the State railways, and M. Robert, engineer of the State railways (secretary), for the purpose of carrying out a series of important experiments on Mr. Behr's lightning express railway, constructed for that purpose in the neighbourhood of Brussels. Mr. Behr says that in the event of the report of the commission being in every way satisfactory, the Government would agree to the building of an important line on his system. A syndicate has been formed in Brussels, consisting principally of some of the leading bankers in that town, who are providing the money for the purpose. The experiments will begin towards the end of this month, and are expected to last about three months.

Cost of Steam in 1870 and 1897.—One the best papers recently read before the American Society of Mechanical Engineers (says the *Scientific American*), was presented by Mr. F. W. Dean, on the decrease in the cost of steam power between the years 1870 and 1897. This was shown to amount to nearly 40 per cent.; 17 per cent. of this is attributed to the use of multiple cylinder engines, steam jacketing, higher steam pressure and superheating the steam. Five per cent. is due to the use of vertical engines, 7 per cent. to improved boilers, 7 per cent. to economy realised in heating the feed water, and 2 per cent. is put down to the credit of improved construction of grates. Taking the best performances of the two periods named, the least consumption of steam per horse-power per hour in 1870 was 20 lbs., whereas the best for 1897 was 12½ lbs.

Electric Radiation.—Prof. Chunder Bose has communicated two papers to the Royal Society on experiments with electric radiation. It will be within the memory of his recent audience at the Royal Institution that a particular feature of his work in this subject is the reduction of the size of the apparatus employed to that of ordinary optical instruments. He has effected this by using oscillations of wave lengths much shorter than were employed by Hertz or Fitzgerald, though, of course, enormously longer than those of visible light. The experiments described refer to the refraction, and total internal reflection, by glass of electric radiation. The experiments on refraction were designed to test the application to glass of Maxwell's relation between the specific inductive capacity and the refractive index. It was found to be 2·04 for the wave length employed (that for visible light being about 1·5), which would make the inductive capacity 4·16. Different observers are said to have assigned to the inductive capacity of glass of various kinds values lying between 2·7 and 9·8. Hopkinson's figures, given by Prof. Everett, range only from 6·57 to 10·1. The second set of experiments was mainly directed to ascertaining the minimum air distance between two parallel surfaces of glass which would produce total reflection, and appear to have given very precise and satisfactory results. In both sets the oscillator used was the form in which a small central sphere is placed between two small spherical beads, the receiver being a Branly tube. The principal difficulty with the apparatus was so to shield the receiver that it should be affected only by radiation from one particular direction, and we may refer our readers to Prof. Bose's papers for the details of the way in which this was met.

The Brighton Engineer.—The condition attached to Mr. Arthur Wright's appointment as manager of the Brighton Corporation Electricity Works, requiring him to give his whole time to the duties of that office, has been waived, and Mr. Wright will be permitted to take private practice as an advising electrical engineer to other companies or corporations outside the borough.

Accumulator Traction on Common Roads.—Before the Self-Propelled Traffic Association on March 29th, Mr. J. T. Niblett will read a paper on "Recent Improvements in Accumulators, and in their Application to Traction on Common Roads."

Comparison Between Horse-Keep and Motor-Keep.—The *Automotor and Horseless Carriage Vehicle* extracts the following interesting comparison made by M. D. Creuzan, President de l'Automobile Bordelais, in *La France Automobile*:—

Daily Keep of Two Horses.

	Francs.
Food, hay, &c. ...	5.0
Litter ...	1.0
Smith ...	0.30
Harness ...	0.50
Rent of stable ...	0.50
Veterinary, &c.; repairs to carriage, stable and harness	1.15
Total ...	8 45

Daily Cost of an Automotor Vehicle.

Daily journey, 30 miles.

	Francs.
6 litres petrol ...	2.10
Oil, waste, &c. ...	0.15
Repairs ...	1.00
Use of rubber tyres, &c. ...	1.25
Total ...	4.50

Daily saving by using an automotor, 3.55 francs.

The editor of the *Automotor* advises his readers to turn back to its issue for October, and read up the article on "Kelvin's Law of Economy," and apply the above figures or others to any given case, a most instructive and accurate conclusion will be reached, viz, that *it is always much cheaper to use an automotor vehicle.*

North-Western Electrical Association.—The sixth annual convention of this Association was held in Milwaukee on January 19th, 20th and 21st. Mr. H. C. Higgins delivered the presidential address. The following were among the papers read:—"Practice of Theory," by J. C. McMynn; "Electric Lighting for Profit," by Alex. Dow; "Topics of Interest to Central Station Men," by Lieut. F. A. Badt; "Long Distance Transmission," by A. Ekstrom; "Present Efficiency of Incandescent Lamps," by J. E. Randall; "Physical and Chemical Properties of Volatile Oils in Boilers," by W. H. Edgar; "Electricity in Municipal Engineering," by Prof. R. B. Owens; "Municipal Socialism," by F. De Land; "Depreciation," by Prof. Jackson. There was a long discussion on municipal lighting plants.

Treatment of Consumption by Electricity.—According to *Electricity*, New York, a well-known physician, Dr. J. Mount Bleyer, is said to have discovered a method of curing consumption by the use of the electric current. Dr. Bleyer's system is based on the well-known principle that electricity can be made to act as a purifying agent by virtue of the ozone which, under certain conditions, it gives forth. Dr. Bleyer revivifies the blood of the patient by giving ozone. He places pads on the patient's chest, directly over the diseased part of the lung, and a pad on the corresponding point at the back. A current of electricity at extremely high voltage is sent directly through the body for 20 minutes or half an hour. Dr. Bleyer does not specify the amount of electricity he uses, fearing that inexperienced professionals may make the experiment with perhaps fatal results; neither does he say whether he uses direct or alternating currents. It has been proven, it is said, by experiments on rabbits, that the electric current really revivifies the blood by giving it ozone. Advanced stages of consumption cannot be cured by the Bleyer system, but it is claimed that such patients as possess enough of the lung substance as will carry on the physiological processes are susceptible of an absolute cure within a reasonable space of time, by the daily application of the current.

The Royal Society.—Before this society yesterday afternoon the following papers were down for reading:—Prof. A. Gray, F.R.S., and Prof. J. J. Dobbie, "On the Connection Between the Electrical Properties and the Chemical Composition of Different Kinds of Glass;" Dr. E. Taylor, "On the Magnetic Deformation of Nickel."

Multiphase Work.—We learn from a Glasgow daily that a handsome new beam and girder shop has been erected at Glengarnock. It is being driven electrically by Mr. Walter Dixon, of Glasgow, on the multiphase system.

Kruger, the Father of Arts and Inventions.—The Government fees in the Transvaal have not, up to the present, been very high; they have now been increased by the Law, and inventors will have to pay:—

	£	s.	d.
At the deposit of the application ...	1	1	0
At the deposit of an objection ...	2	2	0
At issuing a certificate by the Commission ...	1	1	0
For sealing and signing the Letters Patent ...	5	0	0
Before the expiration of the term of 3 years	20	0	0
" " " 5 to 8 years ...	100	0	0
" " " 8 to 11 years	150	0	0
" " " 14 years ...	200	0	0

The preamble of this new fiscal law is exquisite. Whereas it is desirable to encourage the working of new and lawful inventions, by granting to the inventor, for a fixed period, the exclusive right to exploit his own invention for his own benefit. . . . . President Kruger has a peculiar way of encouraging the inventors!

Electric Light Mains.—From the *Birmingham Daily Gazette* we learn that, "the defects in the supply of electric light at Burton-on-Trent were the subject of an important statement by Alderman Lowe. He said the committee had communicated with about 30 other cities and towns where electric light was used, and had ascertained that in almost every case where the Silvertown cables were used there had been more or less serious defects and breakdowns. Through the kind intervention of Lord Burton, a deputation of the Council had been to London and had a conference with Mr. Frank Bailey, engineer to the City of London Electric Lighting Company, and that gentleman had given them some very valuable information, and they hoped to be able to get Mr. Bailey to visit Burton, and to advise them on the best remedy. He had advised the substitution of the British Insulated Wire Company's cables, and this, Mr. Lowe estimated would cost from £5,000 to £6,000." It is not a little curious that the article in our leading pages this week should have a direct bearing upon the subject of mains, and the above note gives very striking evidence that we have struck the keynote of a matter of vital importance to electricity supply companies. We are aware that the manager and engineer of the Gas and Electric Light Works, Burton-on-Trent, issued a circular letter to various engineers throughout the country, in which he complained of the trouble he was experiencing with high tension mains of Silvertown make, and asking for answers to a set of questions which would be treated *as confidential.* Perhaps Mr. Ramsden will be good enough to communicate to us the replies he received to his circular, as we are desirous of investigating this matter; or if the engineers with whom Mr. Ramsden communicated will send us copies of their replies, we shall be glad to receive them, *absolutely* in confidence. It would be interesting also to learn whether Mr. Frank Bailey had advised the substitution of another kind of cable for those of Silvertown, on the strength of a personal examination and test! Finally, we wish to ascertain whether the mains complained of in 30 cities and towns were jointed and laid by the Silvertown employés, how many years they have been laid, and whether before or after the Board of Trade regulations? We hold no brief, it is scarcely necessary to say, for any cable or other firm; but we cannot forbear entering a protest against a line of policy which seems to have been organised for the express purpose of producing a "scare" in rubber cables.

Reis Memorial.—The Physikalische Verein of Frankfort-on-the-Maine propose to erect a memorial to the late Philipp Reis, the inventor of the telephone. The society, of which Dr. Petersen is the president, have appointed a committee to further the scheme, the carrying out of which is estimated to cost about £1,500.

Forthcoming Book.—Messrs. Crosby, Lockwood & Son announce that the work on "Submarine Telegraphs: their History, Construction, and Working," by Mr. Charles Bright, F.R.S.E., will be published very shortly. The subscription price ceases to apply on the date of publication. Subscription orders should reach them not later than Monday, February 28th.

The Shannon Water-Power Scheme.—The *Times* for Monday contains some particulars of this scheme. A meeting of riparian promoters and others interested in the fisheries of the Shannon was held on Saturday to consider the scheme, from which the promoters anticipate important results in the public electric lighting of various centres in Ireland. The scheme, in which Lord Lurgan, Sir Gerald Dease, and other gentlemen are concerned, is for the erection of electric works and machinery at Landscape, on the Clare side of the Shannon, below Castleconnel, the intake for the supply of water for the turbines being between Castleconnel and O'Brien's Bridge. The canal, a cutting of some two miles in length, will convey 55,000 to 60,000 cubic feet of water per minute for the turbines during the 10 hours of each day that they are to be worked. To meet any deficiency of the volume of water in the summer months, and during seasons of drought, the syndicate proposes to store water at Lough Allen, which has an area of 9,000 acres, the 60,000 cubic feet of water required to work the machinery being by this means available, without possible detriment to other interests, when it could not be had through the ordinary flow from the river. Other safeguards are also mentioned, and the syndicate states that it is prepared to compensate any injury proved to be done to the fisheries by the contemplated works. Lord Massy presided at the meeting, and there was a large attendance, including Lord Lurgan, Sir Gerald Dease, Mr. H. C. Fuller, engineer of the proposed scheme, Mr. V. W. Brown, and Mr. Fitzgerald, C.E. Mr. Fuller explained the details of the scheme, which was subjected to criticism from several gentlemen present. Lord Lurgan asked those present to look on that as a preliminary meeting, and to arrange for conferring with him and his colleagues after a reasonable time had elapsed, and when the details were more advanced. The enterprise was a very large one, he might say a national enterprise, and it should not be lightly cast aside. A further meeting will be held at an early date.

Stone-Throwing at Telegraph Wires.—The Education Department, Whitehall, has been circularising the correspondents of schools on the great damage done to telegraph wires and insulators through mischievous stone-throwing. The following circular, which was issued in 1875 and 1885, is again being sent out:—"The Duke of Richmond is informed that so much damage is done to postal telegraph lines by stone-throwing, that her Majesty's Postmaster-General is compelled to put the law in force against offenders. Most of the damage is caused by mischievous persons; but it is found that much injury is done by school boys, who do not think they are doing any great harm, and are not aware that they render themselves liable to imprisonment, and perhaps to flogging. You are hereby requested to be good enough to caution the children in your school against throwing stones at the telegraph lines, and to impress upon them the risks they run, and the great expense, trouble and annoyance they cause by so doing."

Early Electric Tramway Practice in the States.—We quote the following editorial from the *Street Railway Journal*:—"In the discussion of Philip Dawson's paper on 'Electric Traction' before the (London) Institution of Electrical Engineers, one of the speakers is reported to have denounced with vigour and point 'American haphazard methods. Their standards are no standards at all; they go full speed ahead, and then have to go astern.' There is possibly some basis for this criticism. Nearly the entire burden of experimentation in electric traction has fallen upon America, and it is inevitable that there should have been much duplication of plant in the progress of an industry from birth to what we might call now, perhaps, middle age. Nevertheless, there is one element in the case which is too frequently overlooked by the more conservative engineers and tramway managers both here and abroad, and that is, that the pioneers in the industry who have gone ahead courageously and put in the best apparatus known at the time, have frequently made enough money by doing so to purchase more improved apparatus as it has come out. This is true not only where there has been competition, and where the lines equipped with the better motive power have gained traffic at the expense of their more conservative competitors, but also in cities where there has been no competition, for the development of the 'riding habit' in American municipalities through the introduction of electric traction has been one of the marvels of the American financial world. Sooner or later this feature will, of course, be understood more generally abroad, but meanwhile 'conservatism' will, no doubt, plume itself upon its wisdom, while somewhat forgetful of certain advantages of 'progressiveness.'"

Portable Tools.—We have pointed out that electricity is working in the direction of portable tools where the work is large. *Machinery* illustrates a very convenient portable boring and drilling machine by the Newton Tool Works of Philadelphia. This machine has a base with slide, carrying a stout post. The post carries a horizontal spindle. There are two motors in the machine; one drives the machine and the feed, the other serves simply to raise and lower the head upon the post. The boring bar is driven by a steel worm and phosphor bronze wheel, triple threaded. A lifting shackle is provided for the crane hook to take. The machine is specially adapted for the drilling of the large yokes of motors and dynamos, but is, of course, applicable to any other work. It is a good sample of the new departure in tool making, which electricity has brought about, and which would have hardly been practicable—scarcely, indeed, possible without the new agent of transmission.

NEW COMPANIES REGISTERED.

Rochdale Electric Company, Limited (55,887).—Registered January 31st, with capital £5,000 in £1 shares, to adopt an agreement with W. D. Watson, and to carry on the business of electricians, suppliers of electricity, electrical engineers, electrical apparatus manufacturers, &c. The subscribers (with one share each) are:—W. D. Watson, Falinge Road, Rochdale, silk manufacturer; R. T. Golding, 25, Cambridge Road, Seaforth, Liverpool, chartered accountant; T. Snape, J.P., The Gables, Croxteth Road, Liverpool; T. Watson, Carr Hill, Rochdale, silk manufacturer; Miss M. G. Lendrun, 5, Croxteth Road, Liverpool; Mrs. M. M. Watson, Lydstep, Falinge Road, Rochdale; R. Watson, Oak Cottage, Shawclough, silk manufacturer. The number of directors is not to be less than two nor more than four. The first are T. Snape and W. D. Watson. Qualification, £100; remuneration as fixed by the company. Registered by C. Doubble, 14, Serjeant's Inn, E.C.

Warrington and District Electric Light and Power Company, Limited (55,890).—Registered January 31st with capital £2,000, in £1 shares, to adopt a certain agreement and to carry on the business of electrical and mechanical engineers and contractors, electricians, suppliers of electricity, iron and brass founders, &c. The subscribers (with one share each) are:—R. W. Francomb, Wilderspool, near Warrington, merchant; W. H. Robinson, 49, Wilson Patten Street, Warrington, secretary; J. Cannell, Academy Street, Warrington, physician; A. Curran, Grappenhall, Chester, civil engineer; A. Polley, Wilderspool Road, near Warrington, gentleman; H. W. Francomb, Wilderspool Road, near Warrington, student; C. L. Clarke, 7, South Parade, Manchester, electrical engineer. Table "A" mainly applies. Registered office, 117, Sankey Street, Warrington.

Electrical Works Company, Limited (55,892).—Registered February 1st with capital £10,000 in £1 shares, to carry on the business of electricians, mechanical engineers, suppliers of electricity, and manufacturers of electrical apparatus. The subscribers (with one share each) are:—W. M. M. Forwood, 15, Union Court, Liverpool, solicitor; C. O. Grindrod, 11, Knowsley Road, Rock Ferry, Chester, gentleman; A. E. Haptie, 5, Durham Road, Seaforth, Liverpool, clerk; F. W. Lintern, 104, Northbrook Street, Liverpool, clerk; A. Ruckley, 8, York Road, Seacombe, Chester, clerk; R. Smith, jun., 14, Bramham Gardens, South Kensington, gentleman; J. T. Downes, 8, Marlborough Villas, Wimbledon, clerk. The number of directors is not to be less than two nor more than seven; the subscribers are to appoint the first. Registered by F. J. Leslie & Co., 15, Union Court, Liverpool.

Perth Electric Lighting Company, Limited (55,898).—Registered February 1st, with capital £1,000 in £1 shares, to carry on at Perth, W.A., or elsewhere, the business of electricians, mechanical engineers, suppliers of electricity, and electrical apparatus manufacturers. The subscribers (with one share each) are:—E. Pope, St. Stephen's Chambers, Telegraph Street, E.C., gentleman; J. Doyle, 22, Brompton Square, S.W., gentlemen; J. D. Mackenzie, 12, Redcliffe Square, S.W., gentleman; G. T. Bean, 257, Winchester House, E.C., chairman of company; H. J. Dixon, 257, Winchester House, E.C., secretary; J. J. Daynes, 22, Graham Road, Lower Edmonton, gentleman; F. R. Wolseley, Elmwood, Catford, S.E., gentleman. Table "A" mainly applies. Registered by Williams and Neville, Winchester House, E.C.

Perth Tramways, Limited (55,935).—Registered February 4th with capital £125,000, in £1 shares, to acquire, own and work any concessions, rights and privileges connected with the construction and laying down of tramways in Perth, W.A., or elsewhere, and to equip, maintain and work by electricity, steam, horse, or other mechanical power such tramways. The subscribers (with one share each) are:—E. Pope, St. Stephen's Chambers, Telegraph Street, E.C., gentleman; J. Doyle, 22, Brompton Square, S.W., gentleman; J. D. Mackenzie, Bart., 15, Redcliffe Square, S.W., gentleman; G. T. Bean, 257, Winchester House, E.C., chairman of company; H. J. Dixon, 257, Winchester House, E.C., secretary; J. J. Baynes, 22, Graham Road, Edmonton, N., gentleman; F. R. Wolseley, Elmwood, Catford, S.E., gentleman. Registered without articles of association. Registered by Williams & Neville, Winchester House, E.C.

Buenos Ayres and Belgrano Electrical Tramways Company, Limited (55,957).—Registered February 5th with capital £850,000 in £5 shares (40,000 "A" preference, 30,000 "B" preference, and 100,000 ordinary), to adopt agreements with the Buenos Ayres and Belgrano Tramways Company, Limited, and to acquire, own, and work any tramways, light railways, cars, omnibuses, engines, electrical plant, &c., in the Argentine Republic, or elsewhere. The subscribers (with one "B" preference share each) are:—H. Dixon, jun., 6, Vale Road, Finsbury Park, N., gentleman; G. Proctor, 100, Harberton Road, Whitehall Park, N., gentleman; P. H. Lyne, 7, Ledbury Road, South Croydon, gentleman; A. S. Farmer, Holmside, Arkley, Herts., gentleman, B. J. Tunbridge, Eden House, South Woodford, gentleman; B. G. Gouk, 3, Inderwick Road, Hornsey, N., gentleman; E. Temple, 30, Byron Avenue, East Ham., E., gentleman. The number of directors is not to be less than four nor more than seven; the subscribers are to appoint the first; qualification, £500; remuneration £1,500 per annum, and 10 per cent. of the net profits, after paying 5 per cent. per annum on all shares dividend. Registered by Ashurst & Co., 17, Throgmorton Avenue, E.C.

La Capital (Extensions) Tramways Company, Limited (55,966).—Registered February 7th with capital £100,000 in £1 shares, to acquire, work, and turn to account a concession for the construction and working of tramway lines from a point on the system of La Capital Tramways, Limited, to Mataderos, in the Argentine Republic, and to carry on the business of an electric light and supply company. The subscribers (with one share each) are:—S. H. Granger, 271, New North Road, N., clerk; F. Thursby, 10, Draper's Gardens, E.C., solicitor; C. Hamwerck, 125, Goldhurst Terrace, N.W., gentleman; T. Hinds, 12, The Avenue, Blackheath, secretary; G. H. Short, 13, Cross Street, Hatton Garden, E.C., manager; J. C. Pease, 58, Jermyn Street, S.W., advertising expert; J. N. Bartlett, 2, George Villas, Prince's Road, Romford, clerk. The number of directors is not to be less than three nor more than seven. The subscribers are to provide the first. No qualification; remuneration as the company may decide. Registered by Budd & Co., 24, Austin Friars, E.C.

Self-Charging Electrical Traction Company, Limited (56,043).—Registered February 10th with capital £100 in £1 shares, to acquire, own and work, any patents and rights relating to the production, treatment, storage, application, distribution and use of electricity, and particularly in relation to the use of electricity for the purposes of the propulsion of vehicles. The subscribers (with one share each) are:—F. S. Gaylor, 74, Stockwell Park Road, Clapham, clerk; T. G. Norris, 6, Prideaux Road, Clapham, stationer; P. L. D. Perry, 40, Holborn Viaduct, secretary; R. W. Smith, 40, Holborn Viaduct, gentleman; J. Likeman, 47, Holborn Viaduct, registrar; W. O. Wheeler, 252, Cornwall Road, Bayswater, clerk; A. Burgess, 48, Constance Road, East Dulwich, gentleman. Registered, without articles of association, by Steadman and Van Praagh, 40, Holborn Viaduct, E.C.

Dennelle & Co., Limited (56,049).—Registered February 10th, with capital £10,000 in £1 shares, to carry on the business of French art metal workers, brass or metal founders, metal chasers, silk shade makers, manufacturers of wires, cables, and lines, electricians, suppliers of electricity, engineers, &c. The subscribers (with one share each) are:—R. T. Smith, Linford, Essex, gentleman; C. M. Escare, 23, Whitfield Street, W., art metal worker; J. J. Rawlings, Roseles, Galveston Road, Putney, engineer; E. J. Nicholson, 185A, Earl's Court Road, S.W., engineer; C. H. Fleetwood, 196, High Street, Harlesden, secretary: W. R. Rawlings, 6, Gartmoor Gardens, Wimbledon, S.W., electrician; W. Helliwell, 230, Amhurst Road, N.E., gentleman. The number of directors is not to be less than three, nor more than five; the first are E. M. Escaré, and R. T. Smith. Qualification, 50 shares. Registered by Turner & Co., 61, Carey Street, W.C.

Berrenberg Electric Lamp Syndicate, Limited (56,054).—Registered February 11th with capital £10,000 in £1 shares (100 founders), to acquire, own, and work any inventions for the manufacture of electric lamps and similar appliances, and to adopt an agreement with A. Berrenberg. The subscribers (with one share each) are:—G. H. B. Glasier, Edgecombe Hall, Wimbledon Park, gentleman; A. Halford, 7, Pembridge Square, W., gentleman; J. Howard, Blomidon Cranes Park, Surbiton, gentleman; A. Berrenberg, 11, Crystal Palace Station Road, Upper Norwood, engineer; R. J. Preston, 111, Alexander Road, Wimbledon, solicitor; W. J. Collyer, 13, St. Stephen's Road, Bayswater, solicitor; J. S. Glasbo, Ashmere Road, St. Peter's Park, W., clerk. The number of directors is not to be less than three nor more than seven; the subscribers are to appoint the first; qualification, £100; remuneration as fixed by the company. Registered by Burton & Co., 23, Surrey Street, Strand.

Electrical Inventions and Manufacturing Company, Limited (56,073).—Registered February 12th with capital £5,000 in £1 shares, to adopt an agreement with J. Moores and H. O. Farrell, and to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity, &c. The subscribers (with one share each) are:—H. O. Farrell, 15, Hanging Ditch, Manchester, electrical engineer; C. H. Cox, 24, Fern Grove, Liverpool, clerk; J. W. Bennett, Tower Cliff, New Brighton, manager; J. W. B. Lockwood, 22, Trinity Road, Bootle, engineer; J. Moores, 15, Hanging Ditch, Manchester, electrical engineer; M. H. Barber, 10, Corporation Street, Manchester, electrical engineer; J. Woods, Burnage Lane, Didsbury, Manchester, secretary; S. E. Linsell, 33, Holland Road, Chorlton-cum-Hardy, electrical engineer. The number of directors is not to be less than two nor more than five; the first are J. Moores and H. O. Farrell. Registered by Bowden and Widdowson, 19, Brasenose Street, Manchester.

CITY NOTES.

Waterloo and City Railway Company.

The eighth half-yearly general meeting of the shareholders of the above company was held on Thursday, February 10th, at Waterloo Station, Mr. Wyndham S. Portal presiding.

The Chairman said it might interest the shareholders to know that there were now 732 holders, as compared with 669 at the meeting last August, and with 600 at the meeting in February, 1897. After referring with regret to the absence, through illness, of Mr. A. E. Guest, one of the directors, the chairman said that the report and accounts were very plain, and could be easily understood by any shareholder. The accounts as they stood gave satisfactory results, both as to the rate of expenditure in the past, and the probable outlay in the future. They had received the whole of the share capital of £540,000, out of which they had expended £360,605 down to the end of June, 1897, and a further £113,170 had been spent during the past half-year, making the total outlay to December 31st, 1897, £473,776. That total included the sum of £25,000 for interest paid to the shareholders during the construction of the line as authorised by the Act of incorporation. The principal item of expenditure last half-year—£80,037, was made up of £76,765 to the contractors for the works, and £3,272 to the engineers for their services. He regretted to say that one of their engineers, Mr. Galbraith, whose services they valued exceedingly, was very unwell, and his doctor had forbade him to attend the meeting. They had, however, Prof. Kennedy with them, who would be happy to give any information that might be required respecting the engineering work. The next large item in last half-year's payments was £24,839, which was for the electrical equipment of the railway. The interest and commission item, £3,289, represented the amount chargeable to capital under that head, after deducting the credit of £1,992 for interest received on their Parliamentary deposit and their bank account. The probable future outlay of the line was estimated at about £103,000, and that was more than covered by their remaining capital powers, which amounted to £237,890. The sum of £8,333 in the accounts was the amount which the Act compelled them to deduct from their debenture powers, representing one-third of the £25,000 which they had paid for interest out of capital, so reducing their further loan capital powers to £171,666—£7,046 for interest accrued and provided for was the amount divided among the shareholders for the past half-year. At the last meeting he referred to the question of calls, and it was gratifying to be able to state that there were no arrears in respect of their final call, everything having been paid up. The whole of the share capital having now been fully paid up, they were in a position to avail themselves of the provisions of the Companies' Clauses Consolidation Act, 1845, and convert the shares of the company into a general capital stock. The directors advised that advantage should now be taken of those powers, as tending to benefit the shareholders. The stock would be much more marketable, and in a much more convenient form. As regarded the work done in the construction of the railway, he could not do better than read the short but interesting report of the engineers. That report told them that all the tunnels were finished except a portion of the white glazed tiling in the up City Station tunnel, and in the inclined approach to the Central London Company's subways at the Mansion House. In the down or southern tunnel the permanent way had been laid from Waterloo to the cross-over road at the western end of the City Station, and in the up or northern tunnel the permanent way had been laid from Waterloo to the river shaft, and the remaining length of road laying was in hand. The low level station at Waterloo was finished, and two of the three communications between the high and low level stations were finished, and the other one would be ready by the end of the month. The yard for the terminal sidings at Waterloo was finished and ballasted, and more than half of the sidings had been laid. The whole of the permanent way materials for the sidings were on the ground. In the generating station the first portion of the engine and boiler houses is ready for the reception of the machinery. Two engines had been fixed, and all the boilers were now in position. In addition to the engines mentioned above, the remaining four machines and the whole of the dynamos were nearly ready, and the switchboard work and other apparatus for the station was far advanced. The travelling crane was delivered and in use. The electrical work in both tunnels was now complete as far as the river shaft. Beyond the shaft the contractors for the electrical work were following on towards the City as quickly as possible, and would reach the cross-over road in the down tunnel in about a month. The rolling stock had been delivered to the London and South-Western Railway Company, and was now being erected at their Eastleigh Carriage Works. One train is complete, and was quite ready to be lowered as soon as the lifts were ready to lower it into the tunnels. The signalling arrangements had been approved by the Board of Trade. The contract for the work had been let, and fixing would shortly be commenced. The works now remaining to be completed were (1) the permanent way in the up tunnel between the shaft in the River Thames and the City station, and already 80 per cent. of the permanent way had been laid complete. (2) Portions of the platforms and tiling in the City station and inclined approach tunnel, and the short staircase and landing connecting the inclined tunnel with the up and down platforms. (3) The remainder of the buildings at the generating station at Waterloo. All the above were expected to be ready by the middle of March. The large lift for lowering the rolling stock was making good progress, and was expected to be in working order on or before February 20th. Of the two temporary exits for passengers at the Mansion House (pending the completion of the Central London subways), one was well advanced, and it was hoped would be ready simultaneously with the completion of the Waterloo and City Railway. The other was progressing, but its completion depended upon the levels of the gas and water mains at the eastern end of Queen Victoria Street, the exact positions of which has not yet been definitely ascertained by the Central London Railway Company, by whom those outlets were being constructed. It was to be regretted that the Central London Company's subways at the Mansion House would not be ready by the time their railway was finished, and to bring the line into use at the earliest possible date, temporary exits would be provided. They were disappointed that they had not been able to commence the new year with the line open, but that was no fault of the directors or the contractors, nor of the Central London Company. The underground pipes met with had created difficulties and delays which were unavoidable. Those were now disappearing, and they expected to be able to arrange with the London and South-Western Railway for bringing the line into use by the middle or the end of next month. They would, therefore, shortly be in a position to realise the earning capabilites of the railway, and they had every confidence that it would prove of great public service in providing a convenient and expeditious means of communication between Waterloo and the City, and that it would be a safe and profitable investment to those who had contributed to the undertaking.

Col. the Hon. H. W. Campbell seconded the motion, and the report was adopted.

The Chairman then submitted a formal resolution providing that from March 1st the whole of the share capital of the company be converted into general capital stock and divided amongst the shareholders according to their respective interests.

Col. Campbell seconded the resolution, which was carried.

The retiring directors and the auditor having been re-elected, the proceedings terminated with a vote of thanks to the chairman for presiding.

Westminster Electric Supply Corporation, Limited.

The ordinary general meeting of the shareholders of this company was held on Wednesday last at the offices, Eccleston Place, Belgravia, Lord Suffield, K.C.B., in the chair.

The report and accounts having been taken as read, the Chairman, in moving their adoption, said: Gentlemen, the report speaks for itself, and therefore I won't trouble you with a long speech with respect to it. I think you will agree with me that there is every reason to congratulate ourselves on the working of the past year, and the increase in revenue, which allows us to recommend the payment of a dividend, which is an addition of 3 per cent. on that of the preceding year. I think we ought to call attention to the fact that we have had again to make very large extensions in all our centres—Millbank Street, Eccleston Place, and Davies Street—and you can well understand that the extensive works at these stations have put the working of the business at a great disadvantage. The cost of generating the supply might have been far less if we had not had to contend with these difficulties, which arose in consequence of these extensions to our works. But perhaps, on the whole, it is satisfactory as it is. You will see that the supply of current still continues to increase at a satisfactory rate, and, as far as we can judge, there is no likelihood of a decrease in the number of applications received, for as the old houses in some parts of our district where no electricity is used are pulled down, they are replaced by new buildings, in many places by large blocks of flats, where electric fittings are put in as a matter of course. I think you will agree with me that the negotiations with the holders of the founders' shares has been satisfactory, because there is no doubt that it is to the advantage of all concerned that all the shareholders are now upon the same footing. I think that arrangement is satisfactory to the proprietors generally. I do not think there are any other points I can usefully draw your attention to, but, of course, if any shareholder present has any questions to ask, I shall be most happy to reply to them. I now move the adoption of the report and accounts.

Mr. E. Boulnois, M.P., seconded the motion, which was carried.

Mr. J. Browne Martin then moved: "That a dividend be declared for the past half-year at the rate of 16 per cent. per annum, less income-tax, payable on March 1st, making, with the interim dividend of 8 per cent., 12 per cent. for the year."

Sir Douglas Galton seconded the resolution, which was agreed to.

Mr. R. W. Wallace, Q.C., in moving the re-election of Lord Suffield as a director, remarked that he need say nothing concerning the qualifications of his Lordship, who made an excellent chairman, under whom he and his colleagues were very pleased to work.

Mr. Hayes Fisher, M.P., seconded the resolution, and said that outside the work which Lord Suffield did in the board room, his personal influence had been of great assistance to the company in other ways.

The motion was carried.

Mr. Wallace next proposed the re-election of Mr. Boulnois as a director, and remarked that he did an immense amount of work in connection with the company, and he especially looked after the transfer department.

Sir D. Galton seconded the proposition, which was agreed to.

Mr. Boulnois, in thanking the meeting for his re-election, said he took a pleasurable interest in the proceedings of the company, of which he had been a member since its formation. He had watched its rise from infancy to its present position, and any man might be proud to be associated with a concern which had made such vast strides during the few years it had been in existence.

The Chairman also thanked the meeting for his re-election, and said that he had always devoted a large amount of attention to the company since he had been on the board. He had been associated with it from the commencement, and it gave him great pleasure to see the progress it had made.

Sir Mark Stewart, Bart., M.P., proposed the following resolution, of which he had given notice: "That the directors shall be paid out of the funds of the company by way of remuneration for their services, the sum of £3,000 per annum, or such other sums as the company in general meeting may from time to time determine, and such remuneration shall be divided among them in such proportions and manner as the directors may from time to time decide" He said he did not think his task would be a very difficult one seeing the prosperous nature of the company. They had something like 180 miles of ways, and they paid something like £50,000 a year dividend, and they had an increasing number of lamps, so that the prospect was that their profits would continue to increase. Ever since the company had been started, it had been progressive. The first year it paid no dividend, but since that time not only had the shares gone up in value, but there had been a steady rise in the dividend. The shares were now four times their original value, owing to the splendid position which the company occupied. He knew the company had got a good district to work, but that would have been no use if they had not been fortunate in obtaining the services of good directors, and he must say that seeing the responsibility that was entailed upon them, they had not justly compensated them for their labours in the past. The increase in the value of the shares and in the dividends had not been by great leaps and bounds, but it had been a steady graduated process, which he hoped would continue. He was anxious to move that resolution a year ago, but was asked not to; but he thought the time had now come when they really ought to increase the remuneration of the board as he proposed.

Mr. F. A. White seconded the resolution, and said he did not think that anybody could say that the present remuneration of the board was fair or reasonable for the amount of work they had to do.

The resolution was agreed to, and the proceedings closed with a vote of thanks to the chairman for presiding.

National Telephone Company.

This company's meeting was held yesterday at the Cannon Street Hotel.

Mr. J. S. Forbes proposed the adoption of the report in a lengthy speech, and complimented the shareholders upon the progressive character of the figures in the accounts. Knowing, as the board did, the very great difficulties which surrounded the company, they felt that the profits were very satisfactory. The income had increased over the previous half-year by £67,600, and the expenses by £37,806, so that there was an increased profit balance of £23,474.

The report was adopted.

Dublin United Tramways Company (1896), Limited.

At the half-yearly meeting, held on the 8th inst. in the Imperial Hotel, Dublin, Dr. William Carte, J.P., presided, and, in moving the adoption of the half-yearly report, gave the following particulars of two companies which they controlled:—The Dublin United Company's results were most satisfactory, showing increased receipts, economic working, and remarkable freedom from accidents. Passengers showed an increase of 1,221,502, representing £5,028, the average fare being 1·39d. for the horse system, and 1d. for the electric; 73,376 additional miles were run. In November last electric traction was introduced on the Clontarf line from Annesley Bridge to Dollymount, with satisfactory results. The speed authorised is 10 miles per hour, and no hitch had occurred. The new power house at Clontarf is built on the most up-to-date system, with best equipments, and in efficiency quite equalled any to be seen abroad. The restrictions as to speed, imposed by the Board of Trade, very seriously affected their receipts on the Dalkey electric system. Unfortunately the Board of Trade had not the power to grant an increased rate of speed, so they had applied to Parliament, and expect, in the coming session, to obtain the same regulations for the Kingstown and Dalkey line as were approved for the Clontarf line. The delay in extending the electric system to Nelson's Pillar, from Haddington Road on the Dalkey line and Annesley Bridge on the Clontarf line, has been unavoidable, owing to the difficulties in arranging with the Corporation. Matters are now, however, settled, and within the next few weeks they hoped to have the electric cars working in to the city. The Rathmines to the sea line is far advanced. They had applied for an Order in

Council to admit of additional lines being constructed in the city and suburbs. Their offer to take over the electric lighting of the city had attracted much public attention. The company considered, from the opportunities at their disposal in being able to use the power stations at night for lighting purposes, they would be in a position to carry out this proposition with advantage to the company and to the ratepayers. But, as it could only be done with the consent and approval of the Corporation, nothing could be done at present. Their application to Parliament for electric powers had been defeated as far as the city and the principal townships were concerned, and the township of Rathmines was promoting a Bill for the expropriation and dismemberment of the tramway system. In considering the present prices of shares they must contrast the position of the company now with what it was at the time when the company was formed. Then they had been unsuccessful in getting electric powers; were threatened with dismemberment by the Rathmines Commissioners; doubts were cast on the titles to our lines; and they were harassed on every side. Since then they had got electrical powers over the whole city and suburbs; they have a certainty of all their lines for 42 years, with 30 per cent. to be added to their then value if the local authorities should decide to purchase the tramways at the end of that period. The public enlightenment on the economy and other advantages of electric tramways had also tended to enhance the price. None of these conditions existed when the company was formed, nor did they seem even probable of fulfilment; and, under all the circumstances, they claimed that they could not have done better for the shareholders of the old company than by securing them in a position which has enhanced the value of their shares by 50 per cent., unless they were prepared for their whole project breaking down at its inception.

Cuba Submarine Cable Company.

The half-yearly meeting of this company was held on Wednesday at the offices of the company. Mr. C. W. Parish, who presided, compared the expenses of the six months under review with those that arose in the similar period of 1896, and the difference was practically £578 in favour of 1897. Alluding to the serious falling off in traffic receipts, which was referred to in the report, the Chairman said that had been principally due to the loss on the French traffic. The shareholders would have been fully prepared for that result, for they were clearly warned last year that the French traffic would eventually go by the new cable from Hayti to New York. A still more serious competitor was the cable between Bermuda and Jamaica, which completed the Bermuda and Halifax route. The chairman then dwelt upon the changes that had taken place since the inception of the Cuba Company, and referred to the loss of income that would accrue to them being compelled to reduce their rates in consequence of the British Government insisting upon a 3s. rate on the New Bermuda line. After referring to a difference that had arisen between their allies, the West India and Panama Company, and themselves, the resolution for the adoption of the report was passed by the meeting.

The National Electric Supply Company.

The ordinary general meeting of this company was held last week at Preston, Mr. H. Booth, J.P., in the chair.

The Chairman, in moving the adoption of the report and accounts, said it was a great pleasure to all the directors to be enabled to recommend a dividend which would be satisfactory to the shareholders. Nearly four miles of additional mains had been laid during the year, and £4,560 was spent on capital account. An alternating plant had been fixed at the works to supply current to Ashton and outlying districts, and an equivalent of 5,000 8-candle-power lamps had been added. The expenses incurred in the reduction of capital had been charged to the revenue account for the year. He hoped that in the future the company would be enabled to materially reduce the price of current to consumers.

Mr. E. Pyke seconded the adoption of the report, and said they looked forward to a very good result for the present year.

The resolution was carried unanimously.

A dividend of 5s. per share to be paid on the ordinary shares was then adopted.

The Epstein Electric Accumulator Company, Limited (in Liquidation).

Mr. P. W. Northey, liquidator, receiver, and manager of this company, has issued the following circular from 28, Victoria Street, Westminster, S.W.:—"As you are probably aware, an action was instituted in the month of July last on behalf of the first debenture holders, and in such action I was appointed receiver and manager and have in that capacity continued to carry on the business of the company. Subsequently, an order was made for the compulsory winding-up of the company, and I was appointed liquidator in such winding-up. An offer has been made for the purchase of the Epstein Company's assets by a new company, which proposes to take over the business as a going concern. The terms of purchase, while not immediately satisfying the entire claim of the first debenture holders (£6,000), give them such interest in the new company, coupled with a guarantee of minimum working capital, that the offer is likely to receive favourable consideration on their part. As to the owners of the second Epstein debentures, these will have the option of applying for fully-paid ordinary shares in the new company, not exceeding in face value the amount of their present holding in second debentures at a discount of 50 per cent. Any such options not exercised by owners will be held at the disposal of other second debenture holders who wish to participate in the new scheme beyond their present holding. The actual assets of the Epstein Company, after collection of outstanding accounts, will be approximately £2,000 in cash, besides:—

	£	s.	d.	
Plant	3,164	17	5	as nominally valued in books on Jan. 1st, 1898.
Stock	3,296	17	11	
Patents	70,050	0	0	

While the before-mentioned offer is under consideration, I desire to invite competitive proposals which may be productive of better results, and I shall be glad to give any desired information with a view to the receipt of ulterior proposals before closing with the one received, which will be open for acceptance till February 26th."

Newcastle and District Electric Lighting Company.

The directors report that the supply of current continues to give satisfaction to the company's consumers, the units sold last year being more than five times the quantity sold in 1890, the first year of the company's operations. The installations connected to the company's mains during the year are equal to 4,400 10-candle-power lamps, bringing the total up to about 32,600, and 642,969 units of electrical energy have been supplied, as against 541,139 units supplied in 1896. During the past year, 3,006 yards of main and branch piping have been laid, together with 4,938 yards of main and branch cable. The gross earnings during the year amount to £5,684 19s. 1d., and after paying interest and making provision for depreciation and reserve funds, the directors are able to recommend a dividend of 5 per cent. for the half-year ending September 31st (less income-tax), which, together with the interim dividend paid in August last, makes the dividend 7½ per cent. for the year.

The Northampton Electric Light and Power Company, Limited.

The annual report to be presented at the annual meeting of shareholders on February 24th, 1898, states that the directors are again able to present a favourable report to the shareholders, notwithstanding several circumstances, but for which the company's progress would have been even more marked. The engineers' strike occasioned much delay and inconvenience, and it is fortunate that no mishap occurred during the busiest season. It became necessary, in view of continued difficulties with the local gas company, to appeal to arbitration on the question of the removal or alteration of gas service pipes, which interfered with the construction of this company's culverts on the safest and most approved plan. The Board of Trade arbitrator has granted the facilities asked for, but at the expense of valuable time, and a resulting loss of revenue. The new system of charging for current has been much appreciated, and will conduce to the advantage of both the company and its customers. The special rebate to consumers during the past year has amounted to no less than £488. The immediate result of this is a loss of income; but the use of electricity for lighting and motive purposes has been so popularised, that the tendency cannot be otherwise than beneficial. The ordinary charge for current is 8d. per unit (less special rebate if shown by the "indicator"); for places of worship 4½d., and for motive power 3½d. (the demand in both cases being at times when the plant is least employed). Discount is also allowed for cash. Further developments are taking place at the company's works. In addition to the two new engines and dynamos referred to in the last report, one more engine of 240 H.P. has been erected, with dynamo complete, making in all six engine and dynamo sets. There has also been fixed a new boiler of a capacity equal to all the three original boilers combined, with an economiser and other subsidiary machinery. Further land and buildings have been acquired, and an additional boiler house has been erected, with a storage tank capable of holding 33,000 gallons of water. A supplemental accumulator battery has been added. The system of supply will be changed over during the present year from two to "three-wire," thereby securing greater efficiency and economy. In view of the increasing demand for current, further plant has been ordered, consisting of boiler, engine and dynamo, all of large capacity. The mains have been extended in several directions during the year. The machinery is maintained in a high state of efficiency.

The balances of the revenue accounts for the past seven years are shown as follows:—

	1891	1892	1893	1894	1895	1896	1897
	Loss £460	*Profit* £308	£536	£762	£819	£1,351	£1,409
Less depreciation ...				£100	£250	£500	£500
				£662	£569	£851	£909

(Shillings and pence omitted).

The lamps in use (at 8 C.P. each) during five years have been 4,600, 5,300, 6,130, 8,014, and 11,084 respectively, motive power being accounted for as lamps. It will be seen by the net revenue account that, after paying interest on debentures and temporary loans to the end of last year, there remains £562 13s. 11d. to be dealt with. It is now proposed to pay a year's dividend on all the shares for the year ending December 31st last, viz.: on 6 per cent. preference shares, £232; on 5 per cent. preference shares, £65 3s. 8d.; and on ordinary shares, at the rate of 2 per cent, £201 0s 3d., leaving £64 10s. to be carried forward. Further shares were issued last year, viz.: ordinary shares to the number of 710, and 3,000 5 per cent. preference shares, but the total debenture issue was not increased. It is now proposed to issue 4,290 further ordinary shares at par, and also to raise £3,950 in 4 per cent. debentures, which will be issued at a small premium. The existing shareholders, debenture holders, and customers of the company will have the first option of taking these shares and debentures.

Messrs. F. H. Thornton and R. Cleaver retire from the board in rotation, and will be proposed for re-election.

The India-Rubber, Gutta-Percha and Telegraph Works Company, Limited.

The directors' report for the year ending December 31st, 1897, to be presented at the 34th ordinary general meeting of the shareholders, to be held at the Cannon Street Hotel, London, on Wednesday, February 23rd, 1898, at 12 o'clock noon, states that after provision for doubtful debts, a net profit for the past year of £41,044 14s. 9d. Adding £22,128 6s. 4d. brought forward, and deducting £12,500 interim dividend paid in July, there remains a disposable balance of £50,673 1s. 1d. The directors recommend the distribution of a dividend of 15s. a share, free of income-tax, amounting to £37,500, making, with the interim dividend paid in July, a total payment of 10 per cent. for the year, and leaving £13,173 1s. 1d. to be carried forward. There has been little cable work during the year. The company's general business has steadily increased, and the steamships have been moderately employed. The factories at Silvertown and Persan are in a high state of efficiency. There was a six months' strike in the engineering departments at Silvertown, which caused some inconvenience and expense, but did not greatly affect the company's business. The block of buildings in which the Melbourne Agency was situated was burnt out on November 21st. Other premises have been taken and new stock has been sent out.

Mr. Darwin retires by rotation, but offers himself for re-election as a director.

Scarborough Electric Supply Company.
